## CHARLES SPRAGUE SARGENT

THE SIXTY - FIFTH VOLUME OF "THE GARDEN"

**Is dedicated.**

**T**HERE is one garden in the United States to which all who are earnest in their love for horticulture, and tree and shrub life in particular, look to as an example of the great work that may be accomplished by a master mind — we mean Brookline, Boston, the residence of Professor Sargent, to whom this volume of **THE GARDEN** is dedicated. Brookline is the home of a man who has acquaintance with the best of British gardens and collections, and knows them better than most Englishmen. He is one of America's great landscape gardeners, and his knowledge of trees in their native habitats is perhaps unrivalled.

Professor Sargent is a great traveller and worker, and his enthusiastic interest in the Arnold Arboretum, Jamaica Plain, Mass., is a matter of common knowledge, and the Linnaean Society recognised this by electing him a foreign member on May 1, 1902.

Few men have travelled more than Professor Sargent in the endeavour to know trees and shrubs and plants generally as they grow in their native wilds, and his works are monuments of industry and research. "The Sylva of North America" is a description of the trees which grow naturally in North America, exclusive of Mexico; it comprises fourteen volumes (quarto), 790 plates, and was issued during the years from 1891 to 1902, it is the finest work on trees ever published. "A Catalogue of the Forest Trees of North America, 10th census report, 1880," a work giving descriptions of trees, the value of their timber, with elaborate tables of the weights, tensions, uses, and other important details; "The Forest Flora of Japan;" "Trees and Shrubs," illustrations of new or little known ligneous plants prepared chiefly from material at the Arnold Arboretum, 1902; numbers of reports on forestry; and a translation of Des Cars' book on "Tree Pruning," the best and most practical treatise on the subject are other valuable works of his.

Professor Sargent is an honorary member of the Royal Horticultural Society.

## INDEX.

## A.

Abutilon Savitzii, 53  
 Acacia armata, 245  
 Acanthids, winter-flowering, 104  
 Accident, a remarkable, 312  
 Achimenes, 118, 311  
 Aconite, the Winter, in Lincolnshire, 131  
 Acrostichums, 389  
 Adiantum farleyense, 244  
 Advice, untrustworthy, 12  
 Agrimonias, the, 82  
 Ailanthus, 111  
 Ainsworth, Mr. Samuel, 228  
 Akebia lobata, 338; quinata fruiting, 37  
 Akebias, 304  
 Alder, the, 319  
 Aldersey Hall, 204  
 Allamanda Hendersonii, 137  
 Alleys, green, 96  
 Alliums, the, 218, 234, 252, 266  
 Almond, the, 283  
 Alnus glutinosa, 319  
 Alpine fête at the Rochers de Naye, 259  
 Alpine plants, cultivation of, 22, 410; the requirements of, 22  
 Amaryllises at Chelsea, 294; at Liverpool, 265  
 Amelanchier canadensis, 255, 360  
 American Carnation culture, 301; garden, the, 81; notes, 84  
 Anæsthetics, flower forcing with, 35  
 André, Mme. Edouard, 16  
 Androsace hedreantha, 307; sarmentosa, 385  
 Anemone blanda Florizel, 267; b. var. scythica, 332; coronaria, a form of, 215; Hepatica Torch, 178; patens, 167; Poppy, 339; sylvestris, 73  
 Anemones, Poppy, 316; St. Brigid, at Christmas, 15  
 Anguloas, 275  
 Annual and hardy flowers for dry ground, 253  
 Annuals, 359; for the garden, 178; the importance of thinning, 183  
 Anopteria glandulosa, 197  
 Antarctic regions, gardening in the, 71  
 Anthurium, 118  
 Apelandra nitens, 71  
 Aphis, woolly, on dwarf Apples, 256  
 Apple Adams' Pearmain, 62; Bismarck, 83; Lane's Prince Albert, 369, 417; Lord Burghley, 228; Northern Spy, 71, 120  
 Applea, 64; dwarf, woolly aphis on, 256; seedling, 15  
 Apricots, 80, 225, 311  
 Aquatics, 27  
 Arabis arenosa, 322; the double, 306  
 Aralia spinosa, 235, 269  
 Arctostaphylos glauca, 307  
 Arctotis aspera, 317  
 Arisarum proboscideum, 422  
 Artichokes, 81; Globe, 154  
 Arum palestinum, 239; at Kew, 210; tricolor, 215; the common, 290  
 Ash, 132  
 Asparagus, 13, 154, 341; and frost, 265, 312; ornamental, 28; plumosa, 153; Sprengeri, 153

 Aspidistras, 243  
 Association, the British Gardeners', 31, 143, 207, 403, 421; "Transactions" of the Scottish Horticultural, 144  
 Aster cordifolius elegans, 234  
 Auricula, the, 3, 92, 162, 236, 321, 391 season, the, 279  
 Auriculas at Slough, 282; seedling, 405  
 Azalea indica, 341  
 Azaleas, 188; Indian, 311; how they are prepared for the English market, 102; seedling, 390  
 Azara microphylla, 304

## B.

Baden-Baden, notes from, 160, 265, 348, 416  
 Balcony gardening for the Londoner, 186  
 Bamboo flowering in a pot, 281  
 Bamboos, 188, 310; the flowering of, 109, 145  
 Banana, varieties of the, 72  
 Bananas, 188, 416  
 Barbary, Thunberg's, 85  
 Bartram, Mr. John Stotert, J.P., 158  
 Baxter Park, Dundee, the, 110  
 Beans, Broad, 242; early under glass, 12; French, 28, 189, 258, 311, 359  
 Bedding plants, 46, 118; spring, 341; summer, 374  
 Beech tree pest, the, 411  
 Beetroot, 258, 326  
 Begonia gigantea carminata, 197; Gloire de Lorraine, 119; Gloire de Sceaux, 128

Begonia Mrs. H. T. Dixon, 153; Perle Lorraine, 214; semperflorens gigantea, 193; Triomphe de l'Est, 349  
 Begonias, 153; new, and the weather, 57; tuberous, 137; winter-flowering, 37; Veitch's, 30  
 Belgrove, Queenstown, 281  
 Bifrenaria (Lycate) Harrisonite, 341  
 Bignonia grandiflora not flowering, 210  
 Bird life, the world's, passing away, 266; plague, the, 345  
 Black Currant bushes, raising, 72  
 Bog garden, 225  
 Books, 44, 65, 103, 396, 416  
 Border, flower, a well-coloured, 3; colour in the, 1; colour schemes in the, 35  
 Borders, herbaceous, 46  
 Borecole or Kales in spring, the newer, 312  
 Boronia megastigma, 245  
 Boronias, 275  
 Botanical laboratory at Cambridge, new, 177  
 Bouvardias, 81  
 Brassavola digbyana, 123  
 Brassicas, the clubbing of, 222  
 Briars, hybrid, sweet, 150  
 British plants, uses of, 59, 204, 229, 245  
 Broccoli, 10, 257; Late Queen, 393  
 Broom, the Moonlight, 375  
 Browallia speciosa major, 153  
 Brown, Mr. William, 104  
 Brunfelsia calycina, 365  
 Brussels Sprouts, 207; early, 326  
 Buchanan, Sir David Carrick, K.C.B., 126  
 Buddleia asiatica, 36, 54  
 Bulb growing at Nairn, N.B., 196; in south Lincolnshire, 180  
 Burford, Dorking, 391  
 Burns, Mr. John, 52  
 Butcher's Broom, the, 106; in fruit, the, 215

## C.

Cabbage, 396; early spring, 222  
 Cabbages, bolted, 273, 312, 356, 394, 157, 326  
 Cacti, hardy, 258  
 Caladium Argyrites, 327  
 Caladiums, 28, 99  
 Calanthe, a new hardy, 282  
 Calanthes, 206; at Woolton Wood, 19; deciduous, 259  
 Calceolaria Burbidgei, 2; fuchsifolia or deflexa, 2  
 Calceolarias, 81, 100, 404; herbaceous, 390  
 California, a note from, 177  
 Calliandra Tweediei, 194  
 Calochortus, 252  
 Camellia flower from the open, 340  
 Camellias, 137  
 Campanula abietina, 409; Barallierii, 203; pyramidalis, 206, 274  
 Canarina campanulata, 372  
 Cannabis, 311  
 Cannell and Sous, Messrs. Henry, Swanley, Kent, 81  
 Canterbury Bell in pots, the, 140  
 Capers, French, 65  
 Cardamine rhomboidea purpurea, 40  
 Carmichael, Mr. William, 278  
 Carnation and Picotee, the florist's, 12; culture, American, 301; diseased, 422; houses, 153; Leander, 365; Malmaison, a yellow, 377; new white, The Bride, 202; Souvenir de la Malmaison, 140; out of doors, 169, 226; the, diseases and insect pests, 7  
 Carnations, 153, 416; border, for market, 349; from seed, 234, 273; insects on, 378; in the town garden, 179, 201, 219; in tubs and window boxes, 219; Malmaison, 258, 404; Marguerite, 219; protecting, 333; tree, 13, 60, 219, 228, 416; tree, all the year round, 289  
 Carrots, 61, 226, 258  
 Cattleya house, the, 327; labiata, 189; superba, 372  
 Cattleyas, 29; long bulbed, 275  
 Cauliflowers, 396; Early Dwarf Erfurt, 222; sowings of, 226  
 Cauliflowers, 46, 242  
 Celeriac, 257  
 Celery, 207, 258, 291, 375  
 Celmisias, some of the, 74  
 Celsia Arcturus, 360  
 Cestrum aurantiacum, 233  
 Charities, the gardening, 120  
 Cherries, 395; and Plums, 80, 326  
 Chicory, 359; as a spring vegetable, 196  
 Chile, rambles in, 143  
 Chimonanthus fragrans, 161; training, 232  
 Chrysanthemum culture, pictorial, practical, 170; General Hutton, 134; Mrs. J. Dunn, 317; novelties, the early distribution of, 129

Chrysanthemum W. H. Lincoln, 53; White Queen, 134; white seedling, from Australia, 18  
 Chrysanthemums, 14, 47, 100, 243, 291, 360; decorative, 73; decorative incurved varieties, 133; early, 195, 294; the newer, 231; in winter, 3; late, 16; miniature Pompon, 111; standard, 342; trained specimens, 342; treatment of cuttings, 61  
 Cider making in Devon, 68, 136  
 Cineraria Lady Thiselton-Dyer, 349; stellata, 280, 399; Webb's Snapper, 261  
 Cinerarias, 243, 358, 360; Farnham Royal, 248  
 Citron and Shaddock in vinerias, 89  
 Clematis, a scarlet, 407; alpina, 332; calycina, 11, 53, 109; paniculata, 91; pruning, 28  
 Clerodendron myrmecophilum, 282  
 Cliantus puniceus and C. p. alba, 339  
 Cliftonia ligustrina, 180  
 Climbing plants, 236  
 Clivia miniata, 197  
 Cockscobs, 300  
 Coleome cristata and vars., 308; at Hatfield, 259; pandurata, 392  
 Coffee tree, Kentucky, 133  
 Colchicum crociflorum, 178; hydrophilum, 203; libanoticum, 165; montanum, 90  
 Cole, Mr. William, 158  
 Coleus thyrsoideus, 206; at Glasgow, 144  
 Colletia cruciata, 38, 145  
 Conifers, 416  
 Conservatory, heating, 106  
 Copse to cottage, from, 42  
 Coptis orientalis, 148  
 Cordyline indivisa, 258  
 Cornelian Cherry, the, 233  
 Cornus Mas, 214, 233, 277  
 Coronilla glauca, 90  
 Corydalis angustifolia, 110; new, 335; rutafolia, 266  
 Corylopsis himalayana, 280  
 Covent Garden Market, 49  
 Crinum, hardy, 20  
 Crocus candidus, 266; reticulatus albicans, 250  
 Crocuses in grass, 161; in Prince's Street Gardens, Edinburgh, 212  
 Crups, thinning, 395  
 Croton turnfordensis, 42  
 Crotons, 46  
 Croydon, spring flowers at, 300  
 Cucumbers, 138, 271, 395, 416; winter, 13  
 Cupressus torulosa, 235  
 Currant, Black, Boskoop, Giant and the mite, 129; bushes, Black, raising, 132; winter pruning of, 152  
 Currants, effect of basic slag on, 31; flowering, 369  
 Cuttings, autumn-planted, 78  
 Cyclamen, a new, 372; a remarkable, 303; at Hatfield, 249; culture, 106; ibericum, 177; Persian, Webb's Perfection, 215; persicum, 374; persicum giganteum, 372; cultural hints, 78  
 Cyclamens, 137; and Primulas at Messrs. Sutton and Sons, 173; hardy, 251; Persian, at Farnham Royal, 196  
 Cydonia japonica pygmaea, 349  
 Cymbidium giganteum Wilsoni, 168, 189; trayanum, Bradshaw's variety, 37  
 Cymbidiums, 154  
 Cypripedium bellatulum, 341; concolor, 341; Godefroye, 341; insigne, 18, 101; niveum, 341; Romulus, 372; rothschildianum, 327  
 Cypripediums, 123; and other Orchids, 169; rejuvenating, 84; some hardy, 392  
 Cyrilla racemiflora, 180  
 Cytisus purpureus, 406; racemosus, 365

## D.

Daffodil Alert, 264; notes, 263, 366; yellow stripe disease, 407  
 Daffodils, abnormal flowering of, 280; and Narcissus in an old orchard, 317; and 1903, 300, 337; for house decoration, 304; from Ireland, 300; in moist ground, 323, 365; in the time of, 318; new, 264, 318; seedling, 376, 417; double, 280; the colouring of, and soil influence, 405  
 Dahlia, Cactus, at home and abroad, 117; for exhibition, the, 268, 92; planting preparations, 163  
 Dahlias, planting, 210, 375  
 Daisy flower, a curious, 404  
 Daisies, double, 130; two pretty, 348  
 Danae Laurus, 106  
 Daphne Cneorum, 271, 366; Genkwa, 74; indica and Violets, 234; indica rubra, 188  
 Davallia bullata Mariessi, 49  
 Davidson, the Rev. Charles, 66

Dendrobium, a remarkably fine, 280; culture, 227; devonianum, 308; glomeratum, 123; leaves, spots on, 210; Phaienopsis schoederianum, 393; splendissimum grandiflorum, 140; thyriflorum, 227; wardianum, 287, 363  
 Dendrobiums, 46; at Weybridge, 275; at Woodhatch Lodge, 241  
 Dicentra chrysantha, 9, 18  
 Dickson, Mr. Hugh, 361  
 Dicylra spectabilis as a pot plant, 213  
 Dipladenias, 243  
 Disa grandiflora, 258  
 Dover, lectures at, 91  
 Droitwich Experimental Garden, 333  
 Dropmore, Maidenhead, in early June, 496  
 Drummond, Mr. David, 246  
 Dublin, a flower fête in, 281, 295  
 Dundee could be beautified, how, 37; flower and fruit market, opening of, 249  
 Dunfermline Carnegie Trust, 89  
 Dusseldorf International Exhibition, 281

## E.

Earl's Court Exhibition, gardening at, 176  
 Edelweiss, 366  
 Edgings, 118  
 Edinburgh Botanic Gardens, plants in, 317, 408; lecture at, 249; park, the new, 348  
 Edwardias, 383  
 Eleagnus multiflorus, 355  
 Elm, 133  
 Emerson, Mr. Thomas W., 85  
 Endive, 359  
 "England's National Flower," 103  
 Epiphronitis Veitchii, 168  
 Eranthemum pulchellum, 197  
 Eranthis cilicicus, 203  
 Erica arborea, 255; carnea, Crocus Sieberii, and C. reticulata, 214; mediterranea, 355; wilmoreaana, 188  
 Erigeron trifidus, 408  
 Escallonias, the, 72  
 Eucalyptus globulus, 249, 294  
 Eucharis amazonica, 137  
 Euponymus, Japanese, 85; Siebold's, 85  
 Eupatorium vernale, 90, 91, 155  
 Euphorbia jacquiniiflora, 374  
 Eury latifolia variegata, 132  
 Evergreens, pruning, 28, 311  
 Exacum macranthum, 10  
 Exeter, flowers from, 245; winter flowers at, 112  
 Exhibition at Regent's Park, proposed big gardening, 90  
 Exochorda grandiflora, 363  
 Exotics, rare, in Ross-shire, 75

## F.

Fabiana imbricata, 365, 408  
 Fagus sylvatica, 95  
 Feijoa sellowiana, 317, 357  
 Fendlera rupicola, 355  
 Fennel, sweet, 373  
 Fern nursery, a, 48  
 Fernery, the, 258, 842  
 Ferns, 28; and wild flowers, the preservation of our, 356; destroying, 247; hardy, 60, 192; tree, in Glasgow Botanic Gardens, 396  
 Fidler, Mr. J. C., the late, 52  
 Fig, pot, a valuable, 161; trees, 154  
 Figs, 46, 170, 291, 359, 395; ripe, for ten months, 90; St. John and Pingo de Mel in spring, 161  
 Fitt, J. H., 16  
 Fleurs Nationales et les Fleurs Politiques, 1es, 261  
 Flora and Sylva, Vol. I., 63, 190  
 Flora of the Island of Jersey, a, 84  
 Floral emblems in churchyards, 383; farms, Wisbech, the, 342  
 Flower forcing with anaesthetics, 35  
 Flower garden, correct planting in the, 271  
 Flowers, British, the destruction of, 195; Christmas, from Devonshire, 15; cut, hints about, 377; from Mr. Greenwood Pim, 391; hardy, for house decoration, 113; mountain, of New Zealand, 269, 303; spring, at Reading, 196; wild, from seed, 299  
 Forestry at Perth show in 1904, 129; new schools of, 177  
 Forsythia, a way of growing the, 282; and Muscari, 317  
 France exports to England, what, 36  
 Fraser, Hugh, 66, 85  
 Freesia Armstrongii, 194, 213, 233  
 Freesias, notes on, 414; resting, 244

Fritillaria Elwesii, 307; Imperialis, 317; persica, 351; recurva, 409  
 Frosts, spring, notes on, 287  
 Fruit and vegetables, grading and packing, 62, 80, 102  
 Fruit bloom, the failure of, 51; Colonial-grown, show of, 407; committee, the departmental, 316; cultivation, extension of, 91; culture, Government enquiry on, 70; culture in Scotland, 109; farms in Sussex, experimental, 265; garden, the, 155; growing, extension of, in Scotland, 71; in Nova Scotia, 233; in Queensland, 31; in Scotland, 177; houses, covering walls of, 256; in Britain, 417; industry, Government committee, 282; prospects, 247, 249; in Scotland, 408; the outlook for, 363; the promise of, 387; tree pruning, 14, 44, 60, 169, 208, 226, 263, 308, 356; trees and flowers, 317; mulching, 259; newly-planted, spring treatment of, 222; orchard, the neglect of, 47; planting, 60; root pruning, 15  
 Fruits, bush, 416; some tropical, 187  
 Fuchsia and its uses, the, 337; splendens, 197, 234  
 Fuchsias, 274; indoors and outdoors, 389  
 Fugosia hakeaefolia, 408  
 Fund, Gardeners' Orphan, festival dinner, 332  
 Fungus, the Bird's-nest, 79

G.

Galanthus cilicicus, 57, 88; Fosteri, 40, 250; nivalis var. Scharloki, 203; octobrensis, 88; plicatus Fraseri, 178  
 Galax aphylla, 84  
 Garden, a town, 32; City movement in Scotland, the, 176; diary, my, 18; in Scotland, a, 49; my sea-coast, in winter, 127; near London, a, 39; ornament, 116; plants, descriptive list of, 316; round about a, 9, 97, 135, 167, 239, 350, 392; the grey, 5; vasea at Inwood, 184  
 Gardeners' Association, plea for a, 333; meeting, the recent, 173; young, instruction for, 26  
 Gardenias, 118, 327; failing, 256  
 Gardening for beginners, 358; vocation, the, 422  
 Garuda in Japan, 150

# THE GARDEN

No. 1676.—Vol. LXV.]

[JANUARY 2, 1904.

## HORTICULTURE IN 1903.

**T**HE year that has gone will be remembered for one feature—a pitiless rain, with a temperature that brought winter into the heart of summer. Disastrous floods, harsh winds, and rain day after day destroyed the harvest, and the frosts of spring and early summer spoil the fruit and even vegetable crops. It has been a dreary year for horticulturists and for trade generally, and we hope devoutly that the year that has dawned will bring greater prosperity to the country and joy to those who revel in their gardens.

But horticultural events increase in the face of all obstacles. The past year has been one of exceptional activity in the gardening world, and the Royal Horticultural and National Rose Societies have flourished exceedingly. The access of Fellows to the Royal Horticultural Society is extraordinary, and due both to the greater zest for gardening in these days and to the exceptional return in the way of tickets for exhibitions and the quarterly volumes of the Journal for the modest subscription that will gain a Fellowship. The present year will mark a great era in the history of this famous society, for in 1904 it will celebrate its centenary by the opening of a new Horticultural Hall and a new garden.

The building of the Hall and the gift from Sir Thomas Hanbury, K.C.V.O., of the garden of the late Mr. G. F. Wilson at Wisley, near Weybridge, are certainly among the most important horticultural events of the past year, and the meetings of the society in the Drill Hall, at Holland House, and in the Temple Gardens have been of much interest. We have seen many of the introductions of Messrs. Veitch and Sons from China, and the lectures given on various botanical and horticultural subjects have proved, we think, more interesting and instructive than usual, as a careful study of the printed papers will show. It is also interesting to notice that the papers read at the meetings of the Horticultural Club have not been less interesting than those before the Royal Horticultural Society, and were made more instructive by the general discussion which invariably follows.

Exhibitions seem to multiply, and in spite of the abnormal weather were, as a rule, very successful. The great Shrewsbury show was a triumph, and the displays at Holland House and in the Temple Gardens were well attended. The Metropolitan exhibition of the National

Rose Society was not brilliant. The date was too early, and Glasgow, the city selected for the provincial display, was the gainer; this was probably the finest Rose show of the year.

A few weeks before the great Chrysanthemum tournament began a memorable exhibition of fruit and vegetables brought many horticulturists to the gardens of the Royal Horticultural Society at Chiswick. The vegetables were remarkable, and the papers read in the afternoon on various aspects of vegetable culture and cookery deserve to be widely read. It is wholesome evidence of the sound condition of English gardening when so much attention is directed to the production of vegetables of high class quality and in improving existing types. We have heard much about certain varieties of Potatoes that are to bring profit to every homestead. We shall await results this year. In the evening of the first day of the Chiswick fruit and vegetable show a great company of gardeners assembled in the Holborn Restaurant as one step towards a greater reunion between the members of the gardening calling than exists at present, and a gardener's association is likely to be the outcome of this demonstration.

Special societies seem to flourish, and, perhaps, are agents for good in their own peculiar way, but we dread to think of the future if these special missions attack every favourite flower, fruit, and vegetable. A calmer judgment may, however, happily prevail. We are glad to see that the National Auricula and Carnation societies, and the Daffodil Society in Birmingham, show no signs of decrepitude. These old florist associations are reminders of the past, which we would not willingly let die. The retirement of Mr. Latham after many years of honourable service as curator of the Botanic Gardens in Birmingham is worthy of record, and his successor (Mr. Humphreys) may be trusted to carry on the traditions of his office.

Death has removed during the past year many a familiar and kindly face from the ranks of the living. We mourn the loss of such a devoted gardener as Captain Torrens (who reintroduced the pretty *Schizocodon soldanelloides*), Mr. A. F. Barron, V.M.H., Mr. James Smith, V.M.H., Mr. Andrew Pettigrew, Mr. R. Mackellar, Mr. William Beale, Mr. J. H. Fitt, Mr. William Thompson, V.M.H., Mr. John Peed, and Mr. William Fell, with several foreign nurserymen and gardeners, from whose skill and experience we have greatly profited.

This necessarily brief summary of a few of the more important events of 1903 is sufficient to show that in the horticultural and scientific world there is no standing still; there is work and progress, much to be thankful for, and little to regret.

## COLOUR IN THE MIXED BORDER.

I HAVE been interested to find from several letters in *THE GARDEN* that I must have altered the planting of my herbaceous borders, *i.e.*, from mixed colours to plants of one colour together, before any of those described there. As in my case it has proved a great success, perhaps some others may be as interested in a description of my border as I have been about theirs.

It suggested itself first to me as the only means I could think of that would remedy the spotty effect, rather like an old-fashioned patchwork counterpane, that even the best herbaceous borders I knew gave, however well the individual plants were grown. Sometimes even the colour of a flower seemed to be counteracted if those on each side of it contrasted too violently with it, so I painted a plan of the borders in water colour, remembering how wonderfully a warm colour gains when seen through or past a cool one, and *vice versa*, and also remembering gradually to change the colours as they can be changed in water colours. For instance, I avoided placing yellows next to blues, as, though the contrast might be good, the two colours could not blend without making green. So I remembered the rainbow and tried to follow that, or at all events not to put any colours next their opposites. The result of this far exceeded my hopes and expectations.

The herbaceous borders I altered are in the kitchen garden, which is square, crossing the garden at right angles, but not in the middle, making a T. The garden is generally entered at the left end of the horizontal cross of the T, through a door in a high wall, and having opened that one walks down a step into a sea of blue. I thought, until I searched for and collected together all the blue flowers I knew to plant at that end of the walk, that blue flowers were few and far between. But I no longer think so, for at almost all seasons of the year this part of the border has been a dream of blue. Some of the best effects in the garden have arranged themselves here. Whether from the mass of high *Delphiniums* at the back, with *Commelina cælestis* and *Salvia patens* in front, or even earlier in the year from a group of nearly black *Pansies* close to a mass of *Myosotis* and near dark purple *Aubrietias*, *Scillas*, and *Iris reticulata*. Blue of all shades and purples give place gradually to mauves and lilacs, and so on. The *Iris*, of all purplish shades down to the palest grey (that makes going into half mourning almost a

pleasure) come in so well here. Then come Funkia, Lilies, and Gypsophilum, and then white, and that brings us to the corner on the right hand between the perpendicular stroke of the T and the horizontal cross. There is a bold group of Yuccas here, and underneath them are planted dainty little white Tiarellas. I remember carefully avoiding (as I note with amusement) a sweet smelling flower for this place, from the same consideration for the eyes of lovers of sweet smells as Miss Jekyll did, only I thought of the little eager noses and precious eyes already so near the sharp Yucca leaves of my three little daughters.

The opposite corner has a large plant of pale yellow Tree Lupins, also cream-coloured Paris Daisies and *Bocconia cordata*; then quite white on both sides for 10 feet or 12 feet, making a cool, refreshing interlude from bright colours. It is also rather shady from a tall Pine tree growing near. Here early in the year are groups of *Lilium candidum*, white Pinks in front and double white Alyssum, that enchanting addition to white flowers, later on Tobacco, Japanese Anemones, double white Stocks, &c., with a good plant of *Thalictrum adiantifolium*. Pink begins on the left side immediately past the shade with creeping Phlox, Silene, large Thrift, Raby Pinks, Ivy-leaved Geranium, and London Pride, and not forgetting *Sedum spectabile* for the butterflies, they love it so, and behind these *Dicentra*, Sweet Peas, and Hollyhocks, these two only red instead of pink continue to the end of the path. Indeed, all along the arms of the T on each side of the walk runs a hedge of Sweet Peas, sown one colour alone, and that colour the right one for the flowers planted in front of it.

Pink becomes orange on each side of the walk, then red, then crimson, and at the end I had a Crimson Rambler Rose on one side and a Paul's Carmine Pillar on the other, climbing up and hanging over rough posts of young Scotch Fir trees.

Early in the year large groups of dark red Wallflowers and of tall, red Gesner Tulips, and humble but most effective little double Daisy rosettes, and a few red *Polyanthus* are some that tell here with good effect. Later large scarlet Poppies and *Paeonies* come in well, but it is the late summer when here the reds really answer best. Even after all the rain last summer I remember several stormy afternoons when the sun shone out brightly before it set and the gorgeous blaze of colour of all the red flowers together was most wonderful. I really think red gains more from neighbouring reds than any other colour. The smallest little spike of red blossom beginning timidly to come out on the plant seems to gain additional effect from another equally small red flower close by. But when it comes to a mass of blood red tall Phloxes, Valerians, Bergamots, Cactus Dahlias, and Gladioli, backed by Mars Sweet Peas, and further behind still tall haughty Hollyhocks of dark shades of red; in front brown-leaved scarlet Lobelias, Sweet Williams, masses of red *Linum* (one mass of flowers), Scarlet *Lychnis*, and pegged down Verbenas, and close beyond orange of all sorts and shades, *Hemerocallis*, *Coreopsis tinctoria*, graceful, wild, and fragrant, always reminding me of lovely gipsy girls; Iceland Poppies, Gazanias, common Marigolds, &c., altogether growing in luxurious irregular masses of glowing colour; I felt it had well repaid the gardener his trouble in replanting over 4,000 plants.

Retracing one's steps as far as the upright stroke of the T, the yellows begin again, change to orange, then to red on each side, then again orange and scarlet mixed, yellow, white, grey, and finally to blue at the other gate.

From no place can both instances of red and blue be seen at the same time. One has to turn one's back on one in order to see the other. The only difficulty, of course, is so to arrange the plants as to avoid blank spaces by always having a plant just coming into flower planted closely to one just going off.

I myself am not above putting in a Henry Jacoby Geranium if a space appears inevitable amongst the red, or a yellow *Calceolaria*, if the *Eschscholtzias* should fail, a purple *Petunia* among the purples, &c., but I hope each year to gain in experience, and that this next, the fifth, summer may be the best we have yet had, and the next better still.

MARY BUXTON.

*Dunston Hall, Norwich.*

## NOTES OF THE WEEK.

### FORTHCOMING EVENTS.

January 16.—Société Française d'Horticulture de Londres Annual Dinner.

January 21.—Gardeners' Royal Benevolent Institution Annual General Meeting at the Covent Garden Hotel; Annual Supper, Covent Garden Hotel, Mr. Leonard Sutton in the chair.

January 26.—Royal Horticultural Society's Drill Hall Meeting.

**"The Garden" Almanac.**—We hope that the Almanac published as a supplement to the current issue of THE GARDEN will be found useful to all who take an interest in horticultural matters. The dates of the chief flower shows and meetings arranged for 1904 are included, as well as other general information. We take this opportunity of thanking all who have so kindly assisted us in its compilation.

**Royal Horticultural Society.**—The first meeting of the committees of the above society in 1904 will be held, as usual, in the Drill Hall, Buckingham Gate, Westminster, on Tuesday next. An election of new Fellows will take place at three o'clock. To prevent misunderstanding, it may be mentioned that the committees of 1903 do not vacate office until the date of the annual meeting, 1904, and in like manner all Fellows' tickets of 1903 are available until the end of January, 1904. At a general meeting, held on Tuesday, the 15th ult., seventy-two new Fellows were elected, making a total of 1,412 elected since the beginning of the year 1903.

**Galega Hartlandi (?)**.—On page 441 an illustration is given of a *Galega* sent to me by Mr. Hartland of Cork. I well remember receiving flowers of it last year, and thought it then of probably hybrid origin. Through a printer's error a query was left out of the title to the illustration last week, and without this an impression is conveyed that the name of the plant is fixed, thus raising it to specific rank. I hope Mr. Hartland will not definitely name the plant until its origin has been determined.—E. T. C.

**University College, Reading.**—**Department of Horticulture.**—Four scholarships to young gardeners will be awarded in January, 1904. Each scholarship is of the value of £45 (inclusive of maintenance and instruction). The student gardeners holding the scholarships will be required to attend, from January to September, a course of instruction in the horticultural department and the gardens of University College, Reading. Candidates must be of not more than twenty-two years of age, and must have worked for four years in public or private gardens. Applications for scholarships must be made on the scholarship form, to be obtained from the registrar. This form of application, accompanied by a certificate of work and character, must be sent to the registrar before January 10. Candidates will be required to pass a simple examination in English, arithmetic, and the elements of horticulture. In awarding the scholarships, previous training and experience will be taken into account. The course of training will consist of: 1. Practical horticulture. 2. Theory of horticulture. 3. Account keeping. 4. Lectures and practical work in botany and

chemistry in relation to horticulture; insects and fungoid pests; bee-keeping. The scientific instruction will be given in the laboratories of the college; the practical instruction in horticulture in the college garden. The garden, seven and a half acres in extent, is well provided with horticultural buildings. It contains, besides a large number of pits and frames, thirteen glass houses used for general florist and market work. The scholarship holders will be prepared for the Royal Horticultural Society's examination. Certificates of proficiency will be awarded on the work done during the course, and on the results of an examination held at the end of the course.

**"The Horticultural Directory."**—For many years this publication has been of value to horticulturists. The present is the forty-fifth year of publication, and gardeners will find it as useful as ever. In addition to the exhaustive revised lists of gardeners, seedsmen, nurserymen, secretaries of societies, and others, there are two new features, viz., a list of instructors in horticulture appointed by county councils, and also the names of all who hold or have received the Victoria Medal of Honour.

**Councillor Mackenzie of Edinburgh.**—A recent number of the *North British Advertiser* devoted its article for the week on "Men of Mark" to "Councillor ex-Bailie Mackenzie," better known to horticulturists as the head of the firm of Mackenzie and Moncur, Limited, hothouse builders and heating engineers. From it we gather that Mr. Mackenzie was born in 1836 in Appin in Argyleshire, and educated at the parish school of Appin. After serving his apprenticeship in Glasgow he went to Edinburgh, where he eventually entered into partnership with Mr. Moncur. The success of the firm is well known, so that it is unnecessary to detail what the *North British Advertiser* says on that subject. It devotes, however, a considerable space to Mr. Mackenzie's career as a public man for the past thirteen years, which has been one of continued success. For the last ten years Mr. Mackenzie has been convener of the Electric Lighting Committee, and it is largely to his ability that the present success of electric lighting in Edinburgh is due. As the journal referred to concludes, "Councillor Mackenzie is a capable man of business, and an enthusiastic worker in the interests of the city."

**Two good winter-blooming plants (Calceolaria fuchsiae-folia or deflexa of Bot. Mag., and C. Burbidgei).**—

The prettiest and brightest ornaments of my winter greenhouse at the present moment are the above-named pair of Slipperworts, which are well worth cultivating when flowers are so scarce. The first-named is a native of Peru, and is well figured in the 105th volume of the *Botanical Magazine* on plate 6431. It was introduced into cultivation some thirty years ago by an Irish firm of nurserymen at Newry, now extinct, from whom I received it about 1878, and have grown it intermittently ever since, as it is somewhat difficult to keep unless constantly propagated by cuttings. It is an exceedingly pretty species, of a neat and compact habit of growth, and exceedingly free-flowering. The second-named is a hybrid between *C. Pavonii* (figured on plate 4525 of volume 76 of *Botanical Magazine*), and *C. deflexa*, raised by Mr. F. W. Burbidge, of the Trinity College Botanic Gardens, Dublin. The first-named parent is an exceedingly coarse grower, and hardly suited for pot culture. The hybrid is about intermediate between its parents, being much less coarse-growing than the first-named, though of a free and branching habit of growth, and producing much larger flowers than the second. Another good winter-blooming greenhouse plant, which has also the advantage of being sweet-scented, is *Eupatorium petiolare*, first sent out by a German nurseryman under the name of *E. Purpussii*, after its introducer, Herr Purpuss. Its colour is bluish-white, and it is very free-flowering.—W. E. GUMBLETON.

**Royal Botanic Gardens, Edinburgh.**—The members of the staff of the Royal Botanic Gardens, Edinburgh, held their second annual assembly in the Gardeners' Institute, Picardy Place, on the 18th ult. Messrs. Wilson and Gow, who were responsible for the

admirable arrangements, are to be highly complimented for their success in providing such an enjoyable evening

**Schubertia grandiflora.**—This valuable stove climber is seldom grown to perfection, nor is it grown to the extent that it deserves to be. I consider it is one of the finest stove climbers we have; it produces large trusses of pure white flowers, the scent being that of a Coconut. It is very free blooming, and bears its trusses on stems from 3 inches to 6 inches long, which make it so useful for cutting, unlike so many other climbers that are almost without a stem. This plant enjoys plenty of moisture when growing and a liberal supply of water. Diluted farmyard liquid manure at intervals is beneficial. It flowers on the wood made the same year, and the shoots must not be stopped. Should mealy bug infest it the most stringent and careful measures must be taken.—J. S. HIGGINS, *Rig Gardens, Cornen.*

**Edinburgh Market Gardeners' Association.**—There was a large attendance of the members of this association at their annual meeting in Edinburgh on the 15th ult., Mr. Blackie, the chairman, presiding. Councillor Waterston, chairman of the Corporation Markets Committee, was also present as a deputation from that committee. The ordinary formal business, including the allocation of the stands in the fruit and vegetable markets, was transacted, and it was stated that the relations between the Town Council and the market gardeners with regard to these had been of a pleasant character during the year. The revenue of the market, so far as derived from the market gardeners, had showed a small decrease. Councillor Waterston assured the meeting that the corporation was most anxious to do everything possible to make the market more comfortable and valuable to the gardeners. The important matter of the railway charges for market garden produce was introduced by an address from Mr. Isaac Connell, the secretary of the Scottish Chamber of Horticulture, who referred to this question, which was recently the subject of a paragraph in THE GARDEN, and suggested a combination of the association and the chamber in taking action in this and kindred questions affecting the horticultural and agricultural interests. It was agreed that the association should affiliate with the Scottish Chamber of Agriculture, and a committee was appointed to make the necessary arrangements.

**A well-coloured flower border.**—After the remarks made by "G. J." on page 405, with reference to Captain Reid's article on page 375, it is difficult to offer any suggestions with a view to helping to improve the arrangements proposed. A few alternatives may, however, be suggested. Hints for an edging to the section of pinks and scarlets are asked for, and "G. J.," Mr. Hindmarsh, and "Evelyn" have made some excellent proposals regarding these and other colours. May I suggest the double German Catchfly (*Lychnis Viscaria splendens plena*), *Armeria maritima lauchiana*, *Geum chiloense plenum*, and *Sedum spectabile*? Something "superlatively lovely, free-flowering, and sweet-smelling" for the edging to the Yuccas, &c., cannot be better supplied than by the old double white Pink, which I have seen used with superb effect by a grass path. If *Linum flavum* does well with Captain Reid it would work well in as a part of his groundwork for the yellows. I quite agree that the Winter Aconite comes in too early for this colour scheme. Good blues in either shrubs or flowers are difficult to obtain, but among the flowers there are some of the Aconitums, *Anchusa italica*, some of the Campanulas, the true *turbinata* making a capital edging. Then there are some of the Polemoniads, and some of the Irises are blue enough to use with perfect propriety. If Captain Reid will form one of his edgings with *Iris cristata* (if it does well with him), then he will be satisfied with its general effect. Although I have suggested white Pinks for association with the Yuccas, I am at one with "G. J." as to the danger of taking away any of the effect of these noble plants.—S. ARNOTT.

**Marquis de Pins.**—We have already made reference to this new raiser of seedling

*Chrysanthemum* in our Paris *Chrysanthemum* report the other week. In our esteemed contemporary and namesake *Le Jardin* of Paris, we observe a capital portrait of this gentleman together with a short biographical notice, in which a few details of his horticultural career appear. The Marquis is quite a young man, and promises to have a most successful future in store. No one who visited the Paris show could have failed to have been immensely struck with the extraordinary display of new seedlings that he set up in such perfect style. Grand Japanese blooms of enormous size filled a large raised bed on the ground, the seedlings being staged in five flowers of each variety. Most of the other well known French seedling growers were represented close at hand, but we will make no comparisons. Time will show, and we can only say that we await with some degree of interest the early possibility of these new seedlings of the Marquis de Pins getting into the hands of our leading exhibitors. As a grower he is little better than a beginner, and as an exhibitor was practically unknown in his own country until last year, although he had twice exhibited locally; that was down south, but last year and this he came up to Paris and there staged his novelties in a way that surprised everyone who saw them. We cannot, of course, say what will be done on this side of the Channel to introduce these novelties into our collections, but at any rate we mention several by name that they may be recognised if the opportunity occurs: Béhé, Mme. Lasies, Mme. de la Motte St. Pierre Nyphon, Poupoule, Belle l'Isloise, Souvenir de Montbrun, Angell, Charles Bacque, Congrès de Bordeaux, Mme. Magoe, Mme. de Castelbajac, and Germanie.—C. H. P.

**Chrysanthemums in winter.**—At this season of the year large quantities of flowers are naturally sought for, and thus my desire to note a few varieties grown here, which are indispensable for the festive season as they all bloom naturally and very freely at this time. Princess Victoria, creamy white in colour, has perfect flowers of great substance, expanding beautifully. From the main stems the blossoms are supported on stiff, long stems, and so lend themselves easily for vase arrangement. Golden Princess Victoria and Pink Princess Victoria are sports from the above, and have all its good qualities; the colours, as their name implies, are very decided. These three varieties are a valuable trio, and would never fail to please. The Queen, white erect flowers, is still one of the best, very robust, and an abundant bloomer. Mrs. W. H. Weeks makes a remarkably fine bush plant also, with well-formed flowers. Mme. P. Rivoire is very effective, perhaps the freest flowering variety, with bold, well-developed blooms of creamy white. L. Canning is an excellent white, a very desirable variety, flowering as it does well into January. All the above are good forms of the Japanese type. Duchess of Edinburgh (*Japanese Anemone*) is a charming variety, well adapted for table decorations, the colour being soft blush-pink. Miss Filkins, bright yellow, is a general favourite for all decorative purposes, retaining its freshness fully ten days after being cut; it belongs to the feathery section. King of the Plumes, deep golden yellow, belongs to the same class, the petals being prettily cut and notched.—G. ELLWOOD, *Swanmore.*

**Potato Northern Star.**—Mr. Beckett deserves the thanks of the readers of THE GARDEN for the warning he gives about the above Potato in the issue of the 12th ult. I have never been quite able to understand the extraordinary prices charged for Northern Star, which may have been very good from the seller's point of view, though where the buyer's return is coming from I cannot quite understand. Mr. Beckett says he saw diseased tubers of Northern Star at the Southampton *Chrysanthemum* show, and probably there have been many more about that have not been heard of. Be that as it may, I undertake to say that in another two or three years' time we shall hear enough of disease amongst Northern Star, and perhaps some of the others of the highly-praised new Potatoes of this year. They are all being weakened by that common error practised by nearly everybody with new plants of an

what I have heard and read, Northern Star was largely increased this last season by single eyes, which were cut out, potted in 3-inch pots, and started into growth in heat. When sufficient growth was made the tops were cut off and struck as cuttings. Later on the whole of these were planted out. Seed Potatoes from these plants have presumably been sold this year, but they cannot have the constitutional vigour of the original stock. No greater mistake can be made with a modern Potato—a highly-cultivated plant liable to a terrible disease—than to weaken its constitution at the beginning of its existence by over propagating it. If we tamper with Nature by trying to make a plant do more than it properly can, and thereby weaken its constitution, then Nature turns round, and we pay the penalty in the shape of fungoid diseases and insect pests. In dealing with highly-cultivated plants of any sort—whether flowers, fruits, or vegetables—it ought to be always remembered that we are increasing one part of the plant at the expense of the remainder, and simultaneously with larger flowers or fruits, or better vegetables, we should try to obtain and keep a sturdier habit and a stronger constitution, as without the latter the former will be found to be of little permanent value.—J. C.

## THE AURICULA.

**PRIMULA AURICULA**—called also Bear's Ears and Mountain Primrose by old growers and writers—is one of the oldest florist's flowers in cultivation. It is a native of the mountains of Switzerland, Austria, and Syria, and, although doubtless preferring the sweet fresh air of its mountain home, yet it has most kindly adapted itself to our modern mode of culture, thriving in country gardens or even in the immediate neighbourhood of our large and crowded towns, where it is cultivated with great success, London, Birmingham, and Manchester each having a thriving Auricula society of its own, whose members meet once a year in friendly contest to compete for the prizes offered.

Coming into bloom as it does in the early spring, it has few rivals in other florist's flowers, and the bright colours—blue, purple, maroon, red, some almost black and yellow, with many other shades attract the admiration of the casual observer and engross the undivided attention of the careful and enthusiastic cultivator during the blooming season. Many old writers on the Auricula recommend composts of a stimulating and mysterious nature, and invented nostrums which would almost appear to have been introduced for the purpose of increasing the difficulties of their culture. These old notions have been swept away, and plain, simple methods are now taking their place. We propose giving cultural notes month by month during the year, which we hope may interest those already growing this charming and fascinating florist's flower, and possibly induce others to take up its culture.

### WORK IN JANUARY.

This month is one of apparent rest for the Auricula, but although the plants in many instances by the shedding of their foliage may be reduced to mere cones, they must not be neglected, for there is work imperceptibly going on below for the formation of the truss of bloom for the coming spring. Any decayed leaves must be removed and air given freely day and night except in frosty weather or when keen easterly winds prevail. Little or no water is required, except in cases where the soil is getting dust-dry, and then only sparingly, and for preference on a morning when the wind is in the southern quarter.

*Bishop's Stortford.*

W. SMITH.

[Readers who desire assistance in Auricula culture should communicate with the Editor.

The object of these notes, which will appear each month, is to increase the popularity of the Auricula, and to this end all questions concerning the flower will be willingly answered.]

## THE ROSE GARDEN.

### ROSE ANALYSIS.—III.

#### AN AUDIT OF THE NEWER EXHIBITION ROSES.

**T**HE audit given below has been introduced for the benefit of the varieties of recent introduction, which it is impossible to place accurately in the tables, owing to their limited records, and to the disturbing influence of a single favourable, or unfavourable, season upon those records. Each of the following voters was requested to place the fourteen H.P.'s and H.T.'s on the audit paper in what they considered their order of merit as exhibition Roses, and to deal in the same way with the Teas.

"In calculating the number of votes it should be understood that a first place vote in the case of the former list is counted as fourteen votes, a second as thirteen votes, and so on. In the case of the Teas a first place vote is only reckoned as three votes, a second as two votes, and a third as one vote, as there are only three candidates on that list, as compared with fourteen in the other one.

"**AMATEURS.**—Mr. J. Bateman, Rev. H. B. Biron, Mr. W. Boyes, Rev. F. R. Burnside, Rev. A. Foster-Melliard, Dr. J. C. Hall, Mr. R. Foley Hobbs, Mr. Conway Jones, Mr. H. V. Machin, Mr. O. G. Orpen, Rev. F. Page-Roberts, Rev. J. H. Pemberton, Mr. A. Slaughter, Mr. A. Tate, and Mr. R. E. West.

"**NURSEYMEN.**—Messrs. G. Burch, J. Burrell, C. E. Cant, Frank Cant, A. Dickson, Hugh Dickson, John Green (Hobbies, Limited), W. J. Jefferies, J. R. Mattock, H. Merryweather, jun., G. Mount, G. Paul, W. Paul, W. D. Prior, J. Townsend, and A. Turner.

#### SPECIAL AUDIT OF THE NEWER H.P.'S AND H.T.'S.

Position in Audit.	Name.	Total No. of Votes.	Votes by Amateurs.	Votes by Nurserymen.
1	Mildred Grant (1901), H.T.	391	188	203
2	Bessie Brown (1899), H.T.	367	174	193
3	Frau Karl Druschki (1900)	339	159	180
4	Florence Pemberton (1902), H.T.	273	124	149
5	Alice Lindsell (1902), H.T.	257	116	141
6	Ulster (1899)	233	93	130
7	Duchess of Portland (1901), H.T.	220	100	120
8	Papa Lambert (1899), H.T.	211	88	123
9	Ben Cant (1902)	210	114	96
10	Gladys Harkness (1900), H.T.	178	79	99
11	Lady Moyra Beauclerc (1901), H.T.	173	72	101
12	Mrs. Cocker (1899)	162	70	92
13	Edith D'ombrai (1902), H.T.	149	70	79
13	Mamie (1901), H.T.	149	74	75

#### TEAS.

1	Mrs. Edward Mawley (1899)	88	45	43
2	Souvenir de Pierre Notting (1902)	57	28	29
3	Lady Roberts (1902)	37	17	20

Placed according to their dates of introduction, the above varieties arrange themselves as follows: *Hybrid Perpetuals and Hybrid Teas*—1899, Bessie Brown, Ulster, Papa Lambert, Mrs. Cocker; 1900, Frau Karl Druschki, Gladys Harkness; 1901, Mildred Grant, Duchess of Portland, Lady Moyra Beauclerc, Mamie; 1902, Florence Pemberton, Alice Lindsell, Ben Cant, Edith D'ombrai. *Teas*—1899, Mrs. Edward Mawley; 1902, Souvenir de Pierre Notting, Lady Roberts.

E. MAWLEY, in the *Journal of Horticulture*.

To anyone like myself, who is interested in new Roses, an audit such as the above, giving, as it does, the opinion of the principal exhibitors of the day, cannot but be, not only interesting, but also instructive.

It was no doubt Mr. Mawley's intention to have obtained the views of an equal number of trade exhibitors and amateurs, but he does

not appear to have received an answer from all of those whom he asked to vote, as a careful inspection of the audit will go to prove that fifteen amateurs voted and seventeen nurserymen. The audit speaks for itself, but I think it will be worth while to obtain a comparison between the views of the nurserymen and the amateurs, and to do this it is necessary to deduct two nurserymen's votes from each Rose in the table, bearing in mind the correct sequence as shown by the total number of votes, so that while twenty-eight votes will have to be deducted from Mildred Grant, two only must be deducted from Mamie. This will give us the following approximate result:

Name.	Votes by Amateurs.	Votes by Nurserymen.
Mildred Grant	188	175
Bessie Brown	174	167
Frau Karl Druschki	159	156
Florence Pemberton	124	127
Alice Lindsell	116	121
Ulster	93	112
Duchess of Portland	7	100
Papa Lambert	9	88
Ben Cant	6	114
G. Harkness	10	79
Lady Moyra Beauclerc	12	72
Mrs. Cocker	13	70
Edith D'ombrai	14	70
Mamie	11	74

The written order is the result of Mr. Mawley's combined vote, the second column the order of the Roses in accordance with the amateurs' vote, the last column the order in accordance with the revised nurserymen's vote.

The first thing that strikes one is the extraordinary likeness between the two results. The first five Roses are the same in each list. Ben Cant is the point of greatest divergence, the amateurs preferring it to Ulster, Duchess of Portland, Papa Lambert, and the remaining Roses, putting it at No. 6, while the trade place it below those named, and also below Gladys Harkness and Lady Moyra Beauclerc, making it No. 11. What is the reason of this? Does it come better as a maiden or as a cut-back? And did the amateurs grow it as a cut-back and the trade as a maiden? These points all no doubt contributed to the varied decisions, but I am inclined to think the principal reason is to be found in the fact that the amateur has remembered its colour, and the nurseryman its form, with the result above mentioned. I personally should have preferred it to Papa Lambert and Ulster; and while I think Duchess of Portland a better Rose than either of the three I can understand others thinking otherwise. Mamie comes very pretty at times, and when better known I think we shall see more of this Rose in the future than either of the three Roses immediately above her in the table.

The audit is particularly interesting to me, as it enables me to compare my own views as expressed in former articles to you with those who are better able to form a correct opinion.

Mr. Mawley, in his comments on the analysis of the H.P.'s, referred to the triumph of Bessie Brown over Mrs. John Laing, and deplored same. If this audit is a true forecast, Bessie Brown's triumph will be short lived, and she will have to give way to Mildred Grant, although I am inclined to think myself that Bessie Brown will take a lot of beating, and of the two I have found her the easier to grow and to exhibit, and I should therefore not be surprised to see her at the head of Mr. Mawley's analysis for some time to come. I do not think she need fear any other one of her numerous rivals so far as I know them.

The audit of the three Teas needs little comment. It, however, shows that good Teas

are scarce, that while we have fourteen Hybrid Perpetuals and Hybrid Teas (and that number might easily have been increased) introduced since 1899, there are only three Teas that can be called exhibition Roses, and not a few have their doubts as to whether one of these three is not more closely allied to the Hybrid Tea than the true Tea. It is to Messrs. Dickson of Newtownards that we principally look to give us our exhibition Roses. I wonder whether amongst the five or six new Roses that come from Newtownards regularly every year, their set for 1904 will contain a new exhibition Tea. It is five years since Mrs. Edward Mawley delighted us. Cannot Messrs. Dickson find one Tea this coming year up to the high standard, which they have compelled us to expect from them, or must we possess our souls in patience a little longer?

It should be noted that out of the seventeen Roses chosen by Mr. Mawley as the best of the new Roses, no less than eleven come from Ireland and only three from England, one from Scotland, the remaining three from the Continent; and, further, that the Irish Roses are the product of one firm, Messrs. Alex. Dickson and Sons.

As one who is keenly interested in all Roses, but especially in the exhibition Rose, may I be permitted at this season of the year to express the hope that Messrs. Dickson's "shadow may never grow less." If I know anything of the firm I am sure the quality of their Roses will not be allowed to deteriorate.

HERBERT E. MOLYNEUX.

Brantwood, Balham, S.W.

## THE FLOWER GARDEN.

### ANNUAL PINKS.

**A**MONG the annual Pinks we have this year especially noticed the following:—*Dianthus sinensis flore-pleno* (the double-flowered Chinese Pink), which greatly surpasses the old Chinese Pink, though the latter still retains its place among those most commendable. The petals are very close together, and show the most brilliant and diverse colours. The plants are dwarf, and develop regularly, which renders this variety especially fit for filling beds or for forming borders to beds of plants of rather high growth.

*D. sinensis imperialis fl.-pl.* (the double Imperial Chinese Pink).—This is a larger and more vigorous Pink than all the forms which precede it. Its colours are as bright as they are varied, and to such a degree that from the sowing of a single packet of mixed seeds fifty different varieties may be obtained.

*D. lanciatius*.—This has elegant and light coloured single fringed flowers. For some years past a host of varieties has been in existence. The following are above the average:—*D. l. atrosanguineus* (deep scarlet), *Reine des Fées* (salmon-pink with white borders), *dwarf Queen of the Fairies*, *Salmon Queen* (of a salmon-red), and the *dwarf violaceous*, with large violet-coloured flowers. Some of these varieties have also produced forms with double flowers. We reserve special mention for the *D. laciniatus zonalis*, with its grand flowers of bright salmon-red and "eye" of black-purple, and for a variety which has deep vinous red flowers. These are certainly the most charming and distinct of the annual Pinks. Their stems are long and strong; the flowers remain open a long time.

To conclude, let us add that the cultivation of the annual Pink is of the most elementary kind. Of all annual plants it is one of the easiest to grow. Sow under glass in March and April in order to plant out afterwards in the open air, or sow at once in the open air where they are required to grow in April or May. Only ordinary care is

required. Or, in order to obtain earlier blooms, the seeds may be sown in autumn, wintered under glass, and the young plants planted out in the spring. JULES BURVENICH, in Belgian paper.

### THE GREY GARDEN.

HAS anyone ever made in England an outdoor winter garden of any kind of importance? It may be done, and though it cannot be very full of flower, yet by planting it rightly it may be a complete garden, furnished entirely with plants and shrubs that show either their very best, or one of their best, moods from the beginning of November till the end of February.

Such a space would rather naturally divide itself into two sections, the first of which may be called the green garden. The green garden would be enclosed within the shelter of the finest hardy evergreens, the best of all being our three grand natives, Yew, Holly, and Box. It would also have flowering tree Ivy in neat bushes loaded with winter flower and fruit, and there would be spreading patches of the great white-flowered Christmas Rose (*Helleborus maximus*) and *Sternbergia* and *Iris stylosa* both blue and white, *Pernettyas* loaded with pink, white, and red berry, *Andromeda axillaris* and *A. Catesbæi* in red-bronze

winter dress, and highly coloured *Berberis Aquifolium*. There would also be strong tufts of the beautiful Victory or Alexandrian Laurel (*Ruscus racemosus*) and the *Gaultherias* (at their best in winter). Then clumps of three hardy Ferns that are conspicuous for beauty in the winter months, namely, Hart's-tongue, Polypody, and the Male Fern, which in sheltered places holds its fronds till some time after Christmas. Two native plants would also be important in this garden, namely, *Daphne Laureola* and the wild *Iris fetidissima*, in full deep green winter foliage, and in November opening its large seed pods and showing their bounty of scarlet-coloured seeds.

Satin-leaf (*Heuchera*) and others of its near relatives, *Tiarella* and *Tellima*, will give colour foliage, and the *Periwinkles* will begin the winter with the Mediterranean *Vinca acutifolia*, and end it with the garden varieties of *V. minor*, while the variegated *V. major* will show well among leaves of darker green. *Skimmias* and *Aucubas* will also find a place in the winter garden, carpeted with *Asarum* and *Galax*, and the small *Euonymus* radicans with the clear, bright, variegated leaves. The grand leathery leaves of the *Megaseas* will also be there in bold masses and in five varieties of green and red-bronze colourings. The plants above-named by no means exhaust the list of those

that might be used, though they have among them some of the most important.

This, the green garden, surrounded by evergreen trees, should lead to the grey garden, where a pleasant surprise will await those who have never seen a number of plants of grey foliage brought together. The chief occupants of the grey garden are Lavender bushes, Pinks, and Carnations, quite strangely beautiful in their masses of bluish grey. Many may have noticed how well Carnations, and especially the common white Pink, look in the depth of winter, their blue-grey tufts looking stronger, brighter, and cleaner than at any other time of the year. The great white Thistles (*Onopordon*) and the Olympian Mullein are important plants in the grey garden, and, beside the hedges of Lavender that mark out the chief lines and masses of the design, there are big bushes of Jerusalem Sage and of Lavender-Cotton, while lesser spaces are clothed with spreading sheets of *Alyssum* and *Cerastium*.

The grey garden is enclosed within walls of grey stone, on which are trained Rosemary and the Cretan *Cistus*, shrubs that, though not exactly grey, have foliage of so cool a tone that they suit admirably with the grey-blue silver colouring of the main planting. There is something particularly cheerful and well dressed about the grey garden

BORDER OF ROSEMARY IN FLOWER: ONE USE OF A BEAUTIFUL SHRUB.

that is most pleasant to see in the short, dark days of the winter months.

The use of spaces so planted is by no means restricted to the winter season, for even though they may be sufficiently clothed in their winter dress many are the lovely summer flowers that may shoot up between the shrubs or through the silver carpet, such as *Gladiolus* and *Galtonia*. There would also be quantities of China Roses in the grey garden in summer and hosts of Lilies in the green.

## THE WILD PINKS.

THE members of this extensive genus form a family of plants of great horticultural value, from some of the species of which are derived the well-known Carnations, Pinks, and Sweet Williams, the various forms of which are almost indispensable for furnishing the garden at various seasons of the year, consisting of, according to Dr. F. N. Williams in his enumeration of the species and varieties of the genus in 1899, of 231 species, distributed throughout Europe—with the exception of Ireland and Iceland—temperate Asia, and North and South Africa, with a representative in the extreme North-West of America. Most of them are perennials, with grass-like foliage, a few have a shrubby tendency, while others again are of annual or biennial duration. Growing under various conditions many are inhabitants of lowland meadows and dry heaths, some few are maritime plants, being found on the sea shore, others are found at various altitudes on the mountain chains, some, like the alpine and glacier Pinks, grow very high up, and are amongst the most beautiful of our alpine plants. A great many are charming rock plants, forming tufts of evergreen glaucous foliage, which show to advantage on ledges in the rock garden, covered in spring with numerous flowers, some species with large flowers borne singly on short stems a few inches high, others have taller branching stems, while others are of erect growth, bearing a number of flowers in a compact head on the top of stems 1 foot to 2 feet in height.

Crossing very readily, as the various species do, it naturally follows that many natural hybrids are found, and Nyman, in his enumeration of European plants, records thirteen, which number is probably considerably under the mark. Those species taking the principal share in the formation of these hybrids are *D. deltoides*, *D. superbus*, and *D. barbatus*. The number of garden hybrids is considerable, and when several species are grown in close proximity it is very rarely that they come true from seed, all kinds of intermediate forms appearing in a batch of seedlings. Propagation by means of cuttings is, therefore, the most reliable way of increasing a particular species or variety.

The following selection includes most of the more distinct and well-defined species in cultivation, some being omitted, owing, not to their lack of beauty, but to the slight differential characters possessed by many of them. The genus may be conveniently divided into two principal groups, and these again may be divided each into two sets.

### Group I. With flowers in heads :

A. Flowers clustered, furnished with numerous membranous or coriaceous bracts.

B. Flowers in approximate heads, no bracts of a distinct character from the leaves.

### Group II. With scattered or solitary flowers :

C. Petals not fringed.

D. Petals fringed.

A. — *DIANTHUS ARBOREUS*. — A frutescent species from Crete, where it is found growing on calcareous rocks near the sea. It forms a

bushy plant, thickly clothed with short, fleshy leaves, bearing heads of pink flowers, the petals of which are bearded, and have dentate margins. A late-flowering plant, it does not bloom till October, and except in favourable localities, in a dry position, it will not survive any but the mildest winters in this country.

*D. ATORUBENS*. — A hardy perennial, growing from 2 feet to 3 feet high, with densely-crowded heads of dark red flowers in summer. A good border plant when grown in a mass, the flowers are freely produced for a considerable period, the stems springing from a tuft of long grass-like leaves. It is a native of South Europe, where it is found in grassy mountain pastures, in dry, open situations.

*D. BISIGNANI*. — Known also as *D. rupicola*, this shrubby species inhabits the maritime rocks of Sicily and Naples. It is a showy half-hardy plant, forming a compact bush about 18 inches high, with slightly fleshy leaves not so dense as in *D. arboreus*. The light-coloured flowers are borne eight to twelve in a head. Under cultivation away from the influence of the sea the leaves are less fleshy, whilst the flowers are often larger and fewer in number in individual heads. Requiring a warm sheltered position it produces its flowers in November. It was introduced into cultivation in 1825.

*D. CAPITATUS*. — This Eastern European species is closely allied to *D. atorubens*, differing in the involucre bracts, which are much broader, with a long acuminate point. The flowers are also lighter in colour.

*D. CARTHUSIANORUM*. — An erect-growing plant, with tufts of long grass-like foliage and tall stems 2 feet high, bearing densely-crowded round heads of small red flowers. Though not so showy as some of the other members of this family, it is suitable for the herbaceous border, where a group of it will keep up a succession of bloom for some time. The petals are bearded and have crenate margins. This species is found in barren places in Central and Southern Europe.

*D. CINNABARINUS*. — Although frequently offered in catalogues, the true plant is rarely seen. It is a handsome species, tall and erect in growth, suffrutescent at the base, with tufts of grassy leaves and stout stems bearing compact heads of true cinnabar red flowers. The glandular petals are paler on the under side, and the calyx is also tinted with red. Although a perennial, it is a short-lived plant in this country, and does not ripen seed so freely as the other clustered Pinks, which fact may account for its scarcity. A native of the mountains of Greece and Asia Minor, it was introduced in 1888.

*D. CRUENTUS*. — Found in Greece and other parts of Eastern Europe, this species very much resembles *D. Carthusianorum* in habit, but the slightly larger individual flowers are of a darker blood-red colour.

*D. GIGANTEUS*. — This tall-growing species in good soil sometimes reaches a height of 4 feet, with stout stems swollen at the nodes, clothed at intervals with pairs of long bright green leaves sheathing the stem at the base. The flowers are numerous, crowded in a close hemispherical head, the surrounding bracts being foliaceous or leaf-like. The dark red petals are toothed and bearded. A perennial, slightly woody at the base, this plant is found among rocks by the seaside in Eastern Europe. It was introduced from Bulgaria in 1828.

*D. INTERMEDIUS*. — Closely allied to the above, this species is found on Mount Olympus in Thessaly, with heads of deep rose-coloured flowers. Var. *ambiguus* is the Servian form of this species.

*D. KNAPPII*. — Made a variety of the following species by some authorities, this yellow-flowered species is a most distinct plant. Although the habit of the plant, which is rather loose and straggling, does not commend itself, it is well worth growing for the colour of the flowers alone. Although equally at home in the border or on the rock garden, it is seen to better advantage in the latter, placed rather high up so that its weak-stemmed flowers fall over a ledge. It is a native of Hungary and countries adjoining.

*D. LIBURNICUS*. — A maritime species, it was originally found on the shores of the Gulf of Quarnero in Istria. It is also found in calcareous soil on the Maritime Alps. About 1 foot to 2 feet high, with capitate heads of bearded red flowers, attended by leafy involucre bracts in August. W. IRVING.

(To be continued.)

## THE LILIES.

(Continued from page 426, Vol. LXIV.)

VAR. *MACULATUM* = *punctatum* differs from the type plant in its taller stature and more robust habit. Flowers large, and heavily dotted in the lower half with black, the dots raised on long petaloid processes which aggregate towards the base, forming a distinct black streak. A very free-growing variety; common in cultivation. Flowers in July and August.

CULTURE AND USES. — This Lily is perhaps better adapted for general border cultivation than any other known to us. It thrives well in soils of deep tilth, rich in vegetable mould, and where the subsoil is a loose gravel. It prefers a full exposure, and though it may be associated with other plants it should have plenty of air. Given these conditions, planting the bulbs early, before the old flower-stems have withered, in order that the autumnal roots may re-establish the bulbs before winter, it is not too much to say the Scarlet Turk's-cap Lily can be grown anywhere. Its first year's growth will be slight, but better than if the bulbs were planted later. Half the failures to establish this Lily are due to late planting, the bulbs lying dormant, or nearly so, for a whole year. This is one of the few Lilies that will tolerate a subsoil of limestone formation, and if rocks approach the surface here and there it will like it so much the better, provided it can get plenty of root run. Soils resting on clay in wet districts must be well drained for this Lily. It is not suited for pot culture as it makes no stem-roots of importance.

*L. colchicum* (Hort.). — See *L. monadelphum szovitzianum*.

*L. columbianum* (Hanson) (the Oregon Martagon Lily). — A pretty miniature of *L. Humboldtii*, and an exceptionally good garden plant, proving very easy to grow in specially selected situations. Bulbs ovate, laterally elongated, white, the scales lance-shaped, curved; roots very stout, proceeding from the base of the growing point only. Stems 3 feet to 4 feet high, slender, hollow; roots none. Leaves whorled, as in *Humboldtii*; small. Flowers 2 inches to 3 inches across, yellow, dotted dull red internally, ten to twenty on an elegant spike, recurved, nodding, resembling in their size, shape, and disposition the European Martagons; anthers yellow, fragrant, common in cultivation. It flowers in July and August; inhabits cool and moist sites in the mountain regions of Oregon and British Columbia. A remarkably dainty Lily.

CULTURE AND USES. — In this we have a Lily which would prove very difficult to grow in the plant border. We must find a cool,

shady slope for it, such as the higher reaches of rockeries would afford, choosing a rocky ledge or deep fissure between boulders where the thick roots could find plenty of moisture, whilst the bulbs would be maintained in a drier condition or they would speedily decay. After sustaining considerable losses in bulbs we copied the essential conditions of its native habitat by throwing up huge ridges of soil and

THRIPS.

1 and 2. *Thrips minutissima*, immature. 3 and 4. *Thrips minutissima*. 5 and 6. *Thrips cerealeum*.

inserting the bulbs in the sides, their roots pointing towards the centre of the ridges, their growing points downwards. This suited the plants admirably, and we can recommend conditions similar to these as being necessary for *L. columbianum* in Britain. There are many places in most gardens whose natural disposition would be all that is required: the sides of a cutting or a natural cultivated bank would do, and this Lily is seen at its best, and grown best raised on an incline higher than the eye level. Planting should be done in October at the latest, before the stems have fully withered. Quite unsuitable for pot culture as its first season's growth is not fully developed.

*L. concolor* (Galish.).—A very variable, neat species from the mountains of Japan, China, and Siberia, long cultivated by Japanese gardeners, who have isolated and grown several forms as yet unknown to British horticulture. Of known forms the scarlet self-coloured (unspotted) plant should be regarded as the type. Bulbs generally compound, two to six crowned, very small, white. Stems two to six, slender, wiry, 18 inches long, purplish below, rooting freely from their bases if the bulbs are buried deeply. Leaves sub-erect, 2 inches long, lance-shaped, scattered. Flowers star-like, one to three on a spike, scarlet, unspotted, paler externally, the petals 1 inch long, lance-shaped, not reflexing but expanding fully, inodorous. Common in cultivation. Flowers in July.

*Var. Ohime* (Hort. Japan), the *L. concolor* of *Botanical Magazine*, t. 1,165, has narrow-petalled smaller flowers, spotted black on the inner surfaces, scarlet. The bulbs are generally larger and one to three crowned.

*Var. Coridion*.—Bulbs, stems, and leaves as in *concolor*. Flowers unspotted, rich yellow, fully 2 inches across. There is also a narrow-petalled, spotted variety of this.

*Var. pulchellum* (Fisch. and Mey.).—Bulbs solitary, as large as a small Walnut, white. Stems 1 foot to 2 feet high, green. Leaves ascending or slightly arching, scattered. Flowers one to four, erect, where numerous a spike is formed, colour reddish crimson, densely spotted crimson in the lower half, the petals slightly reflexing. Rare in cultivation. Inhabits South-Eastern Siberia and China. Flowers in July.

CULTURE AND USES.—This Lily succeeds well in any good garden soil, preferring full sunshine and appreciating to the full a low-growing carpet about its stems, but the carpet should be deep-rooting, because these slender Lilies depend mainly upon their stem roots for support. Helianthemums are excellent plants for this purpose. They afford the necessary sun-screen, they do not grow too tall, and their roots feed at considerable depth. Associated with plants such as these, *L. concolor* and its forms can be grown in any plant border or on a rockery ledge. Their brilliant, starry flowers appear to good effect among alpines and dwarf border plants. They may be planted at any time from September to February. The group is not generally suited for pot culture, but we have grown *pulchellum* well in pans under cool greenhouse treatment. Leaf-soil is the only safe fertiliser; manures of any kind are very detrimental.

G. B. MALLETT.

(To be continued.)

## GARDEN DESTROYERS.

### THE CARNATION — DISEASES AND INSECT PESTS.

CARNATIONS, like most other plants under our care, are liable when under cultivation to be attacked by various insect pests and diseases. Sometimes bad cultivation is the cause; but in other instances it is the healthiest plants and those that have been artificially nourished with stimulating manures that are most frequently attacked. It is quite certain that no plants can ever remain in good health if they are not kept free from diseases and insect pests; and the Carnation is no exception.

I will deal first with insect pests, or the attacks of maggots and grubs, the larvæ of insects.

GREEN FLY is a very troublesome pest, and does more damage to the plants than anything else. It does not disturb the plants out of doors to any great extent; but those under glass are frequently attacked. The best way to destroy them is by fumigation, or if this is not possible dip them in a solution of soft soapy water. I keep a large collection quite clean by fumigating at intervals, on the principle that prevention is better than cure.

THE SPITTLE-FLY will also cripple the plants; but this is not common, and can be easily removed. When a frothy substance is seen on the plants it ought to be removed, and an insect resembling green fly will be found in it; sometimes two are together. A little water should be used to wash off the effects of the spittle or froth. A more troublesome pest than either of these is the

CARNATION MAGGOT.—This is the larvæ of a dipterous fly, which has been named *Hylemia nigrescens*. It greatly resembles the common house fly. This insignificant-looking pest is not to be trifled with, as it does great damage to the plants. It does not attack them so much in the greenhouse as those outside. Seedlings and layers out of doors are badly attacked by it, while layers under glass escape. The flies may be seen busy amongst the plants in April and later. They drop their eggs at the base of the leaves, a small maggot is hatched out, which eats its way down the leaves and into the centre of the plants; it works its way down the leaf under the membrane, a whitish line showing the path it has taken; if its track is followed it may be caught, and if its presence

is discerned in the centre of the plant pick it out with a needle and destroy it. It may be found in the form of a small white maggot or in the chrysalis state, when it is of a brown colour. The centre leaves are often eaten through at the base, and may be pulled out so that the chrysalis or maggot may be found. The plant is often worthless; but it is best to get out the maggots at whatever cost, as the chrysalis may speedily develop another fly, which, in its turn, may be the parent of a fresh brood of maggots; the progeny of these are found on the plants in autumn and winter. There is no other way of dealing with it except to hunt it out as I have described. The

EARWIG will sometimes do much mischief; it makes a snug retreat inside the calyx of the flower, where it finds shelter and food at the same time. It eats through the petals at the base inside the calyx, and the presence of the insect is discerned by the petals falling out. It is very annoying to see choice blooms destroyed in this way. Bean-stalks inserted between the flower-stem and the support will act as a hiding-place for them, when they may be taken out and destroyed. The

EELWORM is another troublesome pest, but fortunately this is not very common; the plants assume a crippled appearance, the leaves are not half their usual length, and their base much swollen and whitish. These are caused by the colony of small nematoid worms inside the leaves; sometimes one or two layers are attacked and others are free from it on the same plant. The only way to get rid of them is to remove the affected layers bodily from the plants and burn them. It is supposed that these worms are in the soil and fasten on the plants. The disease is fully described and illustrated in the "Carnation Manual," published by the Carnation Society. The

WIREWORM is one of the most deadly enemies of the Carnation. It, like the *Tylenchus* (eelworm), is found in the soil, and it works underground. It is the larvæ of certain beetles belonging to the family Elateridæ, known under the popular names of skipjack, snap-beetle, and click beetle. The wireworm is well known. It is of a brownish yellow colour, and remains in the larval condition for three or four years. It is seldom found in ground that has been cultivated for a number of years. Wireworms are found in pasture land, where the beetles congregate and deposit their eggs, the larvæ living on the roots until they pass through the usual transformations to the beetle state. All sorts of remedies have been suggested for

APHIDES.

1 and 2. Winged females. 3 and 4. Wingless females.

their destruction; their numbers may be reduced by trapping; but there is no way known to me whereby they may be annihilated. Carrots are the best traps, or, failing these, Potatoes will answer. Thick slices of Carrot or Potato are stuck upon the end of sticks and are buried under ground where the wireworms are to a depth of from 3 inches to 6 inches.

DADDY-LONG-LEGS OR CRANE FLY.

- 1. Male Daddy-long-legs. 2. Female Daddy-long-legs. 3. Eggs. 4. Grub.
- 5. Chrysalides.

After a week or so examine them, and the wireworms will be found half buried in the tubers or the Carrots. Hundreds may be killed in this way. The

LEATHER JACKET is sometimes troublesome. It is the larvæ of the crane fly or daddy-long-legs (*Tipula oleracea*); it is a voracious feeder, and is generally found browsing on the plants at night. It eats the leaves, and sometimes gouges the centre out; it burrows under ground in the day time, or, if over-gorged with the leaves of choice Carnations, will be found lying at the base of the plants; it must be caught and destroyed. The skin is very tough, hence the name of leather-coated grub.

THRIPS (*Heliothrips hæmorrhoidalis*) entirely spoils the flowers if the pest is not destroyed in its very early stages. Those who cultivate choice blooms for exhibition place the plants out of doors, and when the flower-buds are well developed, but even before they show the colour of the flower, the thrips get inside and the rich colours, crimson, red, rose, scarlet, &c., become streaked and blotched with white, and the white of flakes and bizarres is made of a dirty colour like the dust on the roads. Syringing helps to keep them off, but may damage the flowers. The best way is to get them into the greenhouse and fumigate with tobacco smoke. By shaking the flowers over the hand the lively little insects may be seen leaping about; it may be necessary to fumigate twice.

RED SPIDER (*Tetranychus telarius*) is a troublesome pest with Carnations under glass. Its presence is discerned by the leaves taking a sickly colour (greenish yellow), and they will soon lose their vitality. The insect is very small, almost microscopical, and the best way is to

syringe the leaves as soon as the pest is seen; this ought to be before the damage is extensive. It appears on the under sides of the leaves first, but soon swarms all over them. The

FUNGOID DISEASES are: First, the formidable disease designated "rust" by gardeners; its real name is *Helminthosporium echinulatum*. The appearance of the fungus when it is first discerned on the leaves is something like a blister. This is caused by the development of the fungus between the membranes of the leaves. Presently it will burst through the membrane, and the coffee-coloured spores are widely scattered. Now, it is evident that no application of any kind of fungus-destroying mixture can reach it before it bursts out, and after the

powder is scattered it is too late. The only real remedy is to look over the plants at least once a week, cut off all diseased leaves carefully, and burn them at once. The other fungoid disease is "Spot."—This is named *Uredo dianthi*, and is a very common disease. The plants sometimes suffer badly both in frames and planted out in the open garden. If the plants are kept in a well-ventilated greenhouse they are not attacked, and if badly diseased are put in an airy part of the greenhouse they speedily recover. The diseased leaves may be cut off. A dry, airy atmosphere arrests its progress. The plants will grow out of "spot," but not out of rust. The rust would ultimately kill the Carnations if it is not exterminated.

BACTERIOSIS.—This disease seems to have been imported from America. Mr. C. W. Ward, in his book on the Carnation, says: "The disease shows readily upon leaves recently attacked, in the form of translucent dots in otherwise healthy foliage. Later on the dots enlarge and run together and the leaf finally turns yellow and dries up. Recent observations of this disease seem to have determined that it is caused by the attacks of various insects,

such as red spider, thrips, &c., and wherever the plants are kept free from these insects the bacterial disease does not seem to develop." I advise all amateurs who would excel in the culture of Carnations to keep the plants in a healthy, vigorous condition by giving them abundance of light and air. See that they are kept clean. Avoid all over-feeding, and in the case of winter-flowering Carnations avoid a high, moist atmosphere. A dryish, buoyant atmosphere is best, with a minimum temperature of about 50° to 55°. Careful watering and a free outlet for the water is essential.

J. DOUGLAS.

### COLOURED PLATE

PLATE 1263.

#### NEW SEEDLING NARCISSI.\*

IN the accompanying coloured plate the flowers represent a few of my seedlings from first crosses between trumpet and poeticus Narcissi. According to the current classification the one bicolor bloom falls under *N. incomparabilis*, the rest under *N. Leedsii*, the *Ajax* parent in the former case being yellow, in the latter white. The section *N. Leedsii* includes certain varie-

WIREWORMS.

- 1 and 2. *Agriotes lineatus*. 3 and 4. *A. obscurus*. 5 and 6. *A. sputator*. 7 and 8. Wireworms (natural size).
- 9. Wireworm (magnified). 10 and 11. Chrysalis.

ties which up to the year 1884 were classed separately as *N. Vincenti*. It is questionable whether any Narcissi are more beautiful than the finer varieties of *N. Leedsii*, and Messrs. Leeds and Backhouse, out of all their bequest to English gardens, have perhaps given us nothing more valuable than the union of strength and refinement in such flowers as Duchess of Westminster, Minnie Hume, Mrs. Langtry, Katherine Spurrell, and others. It is noteworthy how in these hybrids the infusion of the poeticus blood has altogether dispelled the weak constitution of the other parent, namely, the white *Ajax*. *N. cernuus*, *albicans*, and *tortuosus*, the plants with which Messrs. Leeds and Backhouse seem to have worked, are notoriously difficult of permanent cultivation in most of our gardens, whereas nearly all the *Leedsii* grow and multiply with almost embarrassing vigour. Of newer varieties, perhaps I may claim for my *White Queen* that it still holds the foremost place, but no doubt the future will see a steady improvement in this as in every other division of the genus *Narcissus*. Tall, robust, fragrant, white-petalled, with crowns white or delicately toned with citron, lemon, or salmon, the *Leedsii* Daffodils are scarcely excelled among our spring flowers.

G. H. ENGLEHEART.

STEM EELWORM.

\* Drawn by H. G. Moon.

NOTES ON HARDY PLANTS

THE NARCISSI AT CHATEAU D'OEX.

**I**n the months of May and June the Alps of the Canton of Vaud become white again and as if covered with snow. Seen from Lausanne or Montreux the pastures of the Dent de Jaman, of Les Avants, and of all the neighbourhood are as white as the snow-covered summits. It is a wave of white that, beginning in the lowlands, creeps up slowly but regularly to the highest regions, only dying out in July on the uppermost pastures at an elevation of 4,000 feet.

with pleasure Mr. W. Irving's note about it on page 334. Mr. Irving remarks that "it is not a suitable plant for the ordinary herbaceous border or for exposed situations, but requires a warm, sheltered position in light soil." This is entirely justified by the general experience of the few who seem to have tried *Dicentra chrysantha* in this country. They have not found it hardy, and it is questionable indeed if it will live for many years even at Kew. This is unfortunate, as it is a plant many of us would like to establish on account of its distinct and pretty appearance. Every now and then it has been offered, and once, some years ago, I had a plant, but it failed me, and the infrequency with which it is offered by the nursery trade would point to its having some fault or other,

last winter. If it has been established for any time some of us will make another attempt to succeed with it, inspired by greater hopefulness than we have had for some time.

*Carsethorn, by Dumfries, N.B.* S. ARNOTT.

ROUND ABOUT A GARDEN.

GARDENS FOR PLEASURE.

As a matter of enjoyment, I do not think that it matters much whether your garden is a good one or a bad one, so long as you take an interest in it; for the sum total of pleasure

NARCISSUS RADIIFLORUS IN THE PASTURES OF CHATEAU D'OEX.

It is *Narcissus radiiflorus* of Salisbury, not, as is generally supposed, *poëticus* of Linnaeus, a kind which is very rare in Switzerland, growing only in the neighbourhood of gardens from which it has escaped. *N. verbanensis* (Herb.) is a small and narrow-leaved form with rather yellowish flowers, which grows near the Lago Maggiore and across the Jura in the Canton of Neuchâtel.

The photographs were taken in the pastures of Château d'Oex in the Pays d'Enhaut (Canton of Vaud) above Aigle and Le Sepey. *Floraire, Geneva.* HENRY CORREVOY.

DICENTRA CHRYSANTHA.

I was about to ask if any of your readers had succeeded with *Dicentra chrysantha*, and observed

unquestionably, so far as my information goes, want of hardiness.

There is a figure of this *Dicentra* in the unfortunately short-lived "English Flower Garden" (conducted by the late Mr. W. Thompson) for 1858, which gives a capital idea of the plant, at that time named *Dielytra* or *Dielytra chrysantha*. It had then been newly introduced, Mr. Lobb having sent seeds home to Messrs. Veitch, for whom he was then collecting. It had flowered with them for the first time in September, 1857, and at the time of the issue of the "English Flower Garden" had not been distributed. It never appears, however, to have become for long an occupant of British gardens, although, as I have already remarked, it has been offered every now and then. It would add to the obligations Mr. Irving has already laid us under if he would inform us how long the plant referred to has been at Kew and also if it was in the open all

which the human mind can extract from a piece of ground remains about the same. In India and England I have had gardens good, bad, and indifferent—gardens so small that it was a pleasure to do all the work in them myself, and, on one occasion at least, a garden so large that during three years I never became fully acquainted with the plants in every part of it, nor at any time during that period knew all the men that worked in it even by sight. Yet, looking back, I cannot say that any one garden gave greater pleasure than any other. If you have only room for one Rose bush, you can make the care of it the joy of your life.

THE COMPENSATION BALANCE.

For somewhere at the back of the human mind there is an invaluable compensation

balance, which works out the proportion sum of human happiness so accurately that at the end there is no rebellious fraction of deficit or excess, and we can start with a clean slate for the next sum, contentedly assured that that will work out evenly, too. By this I do not mean that all people get equal pleasure from their gardens. Some regard them as a costly nuisance; others take mild pride in them as an appanage befitting the status of their mansion, and from this stage the pleasure of gardens and gardening ranges in intensity up to the enthusiastic absorption of the triumphant horticulturist, who seems to live for nothing else. Yet in all these diverse minds there is still the compensation balance which makes up for loss of pleasure, through lack of interest, in the garden by added pleasure arising from greater interest in other things. And I think that peaceful contemplation of whatever beauty one's garden may have, which is the crown of pleasure in our work, brings philosophic insight into this truth. We recognise that though seasons change and gardens change with them, the pleasures and worries remain about the same.

#### GARDEN PHILOSOPHY.

You may sit, weather permitting, to enjoy the autumn sunlight and the best vista of your garden on a sheltered seat, as you have sat, weather permitting, in other autumns; and at the back of your mind will be always the half-formulated thought that the year's failures and successes, its clouds and its sunshine, always work out as a fair sum of human happiness, and that there is no need to blot with tears the clean slate on which you propose to begin another year of gardening experience. At the back of your mind, too, lies the germ of unconscious foreknowledge that when the autumn of your own life comes, it will work out as a fair average sum of human happiness, and that the Great Gardener will not be dissatisfied with his work in you. When we dabble with the earth, following man's primæval occupation, we all come to the same human level, and can see the equality and the goodness and the reasonable joy of life. We soak up the knowledge from the soil.

#### THE PARALLEL OF DEATH.

At the same time, who has not felt moments of impatient revolt against the sameness and repetition of the annual results of effort? Foreknowledge of death is always so near to our minds that we resent its suggestion in the annual fall of the leaf and the withering of the flower. We unconsciously resent the new-made beds of earth, which look so like graves, and we put from us the hateful simile that, as we fill the empty places with new generations of flowers, so our places will be as well filled with new generations of men. It is this feeling, not even expressed in conscious thought, which lies, I think, at the back of the common preference for perennials, in a garden of pleasure, over annuals and bedding plants.

#### THE IDEAL PLEASURE GARDEN.

Indeed, the ideal pleasure garden seems to me to be one in which bare, empty earth should never be seen, where there should be no hoeing or digging, save to make room for the introduction of new plants, and where the ground should always be carpeted with green at least. Having carefully arranged the plan of such a garden in your mind, you should *fill* it with plants—flowering shrubs, herbaceous perennials, creeping plants, and bulbs, as nearly in endless variety as you have space for; and after that you should merely regulate its growth, and remove whatever becomes un-

sightly. By helping the weak against the strong, the delicate against the rampant, and snipping off each weed that might thrust itself up to daylight between the plants, you would ultimately get such an unbroken carpet of flowers and greenery as one sees in dreams of enchanted woodland.

#### A LESSON FROM THE RABBIT.

If the rabbit using only his teeth can convert a whole wood into a rank jungle of Nettles and Elder and Ivy by the simple process of gnawing down every plant which he finds eatable, why may not we, using scissors and shears with discretion and industry, convert a common garden into a place where everything flourishes everywhere in proportion to its beauty? How infinitely better, at any rate, would even half-success in such an effort be than the bare, dank flower-beds arranged in depressing parallelograms, which for many months in the year represent the "garden" view of most dwellers in town! Even common wild woodland is prettier and greener in winter than the average suburban garden; and why, when we have all the hardy gems of the world to choose from, should not these small gardens be nooks of fairyland always, instead of looking like miniature cemeteries for half the year?

E. K. R.

## THE INDOOR GARDEN.

### EXACUM MACRANTHUM.

**N**OT so generally met with in our plant collections as it deserves is this beautiful and distinct plant. According to Nicholson the plant was introduced into this country about half a century ago, and even now there are many gardeners who have not seen it. Its rich blue-purple flowers are from 2 inches to 3 inches in diameter, with large conspicuous golden stamens. Its cultivation may be considered more tedious than difficult, as close attention with a view to keeping the plants free from the small yellow thrips, which appear to be its natural enemy, must be given. Its propagation is very easy, as cuttings made from the points of young shoots strike freely during October, or in fact at any time before the embryo flower-buds are formed. The cuttings should be inserted three or four round the rim of a 3-inch pot filled with light, peaty soil. If placed in a bottom-heat of 70° or 75° in a moderately close case or under a bell-glass almost all will root. When rooted pot them singly into as small pots as practicable in a compost similar to that in which they were rooted, and until a little root action is established keep them in a somewhat close case or in the propagating house. Afterwards place them on a raised stage or shelf some 2 feet from the glass, where they will get the maximum amount of light during the winter months, and in a temperature ranging from 58° to 65° by night and to 75° by day when favoured with a little sun. Syringe them carefully once or twice a day when the weather is favourable.

By the end of February the largest plants will be ready for 3-inch pots, and here I may observe that one of the chief points to be noted in the cultivation of this plant is to keep it in as small pots as possible. Although making comparatively strong roots it certainly grows more freely when the roots have reached the sides of the pot. Good drainage is also quite essential, as a liberal supply of water at the root is necessary. Although I have advised peaty soil it must not be understood that the plant will not grow in loam. I find that it roots equally well in either soil, provided the loam is not cut from a limestone or chalky subsoil. From the time of this potting the treatment will vary but little, the house may be ventilated somewhat freely for a stove house, and a light shade during bright sun will be necessary. Should thrips become troublesome dip the plants twice (one

evening intervening) in XL All Plant Wash, and place them on their sides for half an hour, when a sharp syringing with clear tepid water must be given them. Afterwards replace them on the stage or shelf and attend carefully to shading in the event of bright sun. Those plants rooted in October will be ready for their final shift during March and April, when a 5-inch pot will be ample for the strongest plants; in this size pot a plant will carry from ten to eighteen flowers.

Whenever the pots become moderately filled with roots a regular supply of clear manure water must be given them, that made from sheep manure is preferable. The plants will require occasional pinching to keep them bushy as well as to determine their time of flowering. The natural season of blooming for plants rooted in October is from the middle of May to the end of July, and the period of duration about three weeks if kept in an intermediate temperature and shaded from bright sun. Although the plant is described by botanists as an annual, I have grown some plants for two or three years. By cutting them back immediately after blooming, and repotting them shortly after they have broken into growth, they will return a good stock of cuttings, and may be grown on into shapely plants in 8-inch pots by the following year. Seeds may be ripened by the end of August or the middle of September, and I would advise sowing them as soon as matured. I have, however, found that 50 per cent. will germinate when sown in the January following.

J. JACQUES.

### TULIPS FOR EARLY FORCING.

TULIPS, like all bulbous plants when required for early forcing, must have a preparation. It is essential in the first place that the bulbs be of the best, and also that an early start be made by potting, so that root fibres may be produced in abundance. With this achieved the rest may fairly be stated to be within the control of the grower, and indeed this is so to a considerable extent. Another point of equal value is, of course, the choice of varieties most suitable for early forcing; indeed, without a good selection, the grower may find himself in dire straits if, when the bulbs are placed in heat, they fail to respond in due time. For the very earliest work the Van Thols in their many shades are the most suitable. These dwarf and very pretty Tulips are largely grown for the purpose indicated. The immense quantities grown in some establishments alone would certainly surprise those not closely connected with the work. Such as these may be flowered from November onwards. It is worthy of remark, however, that suitable as these are for early forcing in general, they lose not a little even of their dwarfness if over or too early forced. To follow this group in a general way one or two varieties take the lead, and of white none is more suitable and valuable than the well-known Queen Victoria. Naturally grown, this is streaked with rose, but under good forcing the flowers are quite white and pure. A very pretty white single Tulip is L'Immaculé. This responds very quickly to a genial bottom-heat, but it is not so extensively grown as the first, which is also known as La Reine. This is the standard early white single for the market. A good yellow is Yellow Prince, and very fine, too, is Goldfinch, a pure golden-yellow and sweet scented. This will be much grown in the future; it is of good shape and colour. Of red sorts, perhaps Artus and Belle Alliance are among the best for the above work. To force these Tulips with success a bottom-heat frame within the greenhouse is a necessity. The heat should range from 70° to 85°. The temperature must always be moist and uniformly maintained, starting with 70° at the end of a week it may be increased to 80°. With the bulbs in pots or boxes the latter should be set closely together in the frame on a 2-inch thick bed of Coconut fibre, covering them overhead with the same material to a depth of at least 4 inches. This top covering quickly becomes permeated with the heat, and progress is rapid. A slight moistening now and again may be requisite, but the top covering should not be so wet that the material will remain heavily about the top growth.

The root watering must receive attention before covering up. With the lights placed on and the frames darkened these plants may be brought into flower in about three weeks. The covering should not be removed until the buds and growth generally are well through the plunging material. At this time the material may be removed and the plants replaced in the darkened frame for a few days longer. It is most important that these very early forced batches be not exposed to the lower temperature of the greenhouse before the flower-buds are of full size. If taken out when half grown it is quite likely the whole may be ruined by fogs. Nothing is more injurious to the tender flower-bud of the Tulip in such circumstances. Half-developed flower-buds remain as if paralysed, as indeed they are to a great extent. Fully developed buds may be gradually inured to the cooler conditions as required. Later batches are less likely to suffer from this cause. E. J.

## TREES AND SHRUBS.

### MAGNOLIA GRANDIFLORA.

**T**HIS evergreen Magnolia is most satisfactory in this country as a wall plant, and in the south and west of England grows well and flowers fairly freely under those conditions. It is a noble tree, and the large, white, cup-shaped, fragrant blooms are particularly handsome. A high wall facing south, and recesses between house windows, where it is sheltered from cold winds, and also has room to develop, form good positions for this Magnolia. To have an idea of the height and vigour it will attain, *M. grandiflora* should be seen in some of the Riviera gardens. There it forms a tree some 40 feet to 50 feet high, and is one of the most striking objects even in these exceptionally rich gardens. The thick leathery leaves, deep green above and rust colour below, alone make the tree a handsome one; but when in late summer the flowers appear, filling the air with their fragrance for yards around, and especially in the evening is this noticeable, then it forms indeed a noble garden ornament. So far as the South of France is concerned, however, it is unfortunate that this Magnolia flowers in summer, and thus is never seen at its best by visitors, who rarely arrive there before Christmas.

### CLEMATIS CALYCINA.

**T**HE chief interest of this Clematis centres in its evergreen foliage and early flowering. For general usefulness, however, it is surpassed by most of the other species. It is a native of the Balearic Islands, and was named by M. Richards, a French botanist, *C. balearica*, Aiton's name, *C. calycina*, the name under which it is figured in the *Botanical Magazine* (t. 959), being the one which is kept up. It grows to a height of 9 feet or 10 feet, and makes a dense tangled mass, the leaf-stalks twisting round and binding the branches together. The leaves are very dark green in colour, and vary considerably in shape; usually, however, they are ternate, the divisions being again very deeply divided. The flowers vary considerably in size, being from 1½ inches to 2½ inches across. In colour they are greenish white, with a tinge of purple occasionally appearing on the inside of the sepals. The plant continues to grow very late in the year, young soft shoots with flower-buds being produced in December when the weather is mild. Early in December flowers are often to be seen,

while if the weather is mild in January and February numerous flowers are to be found. Though perfectly hardy in the open about London, it is better grown on a wall, the extra heat obtained by this means producing better flowers. At Rose Hill, Falmouth, there is a nice specimen of *C. calycina*, and in the mild climate experienced there it is said to flower remarkably well, the flowers being clean in colour and of good size. W. DALLIMORE.

### JASMINUM NUDIFLORUM.

**F**EW shrubs flower more freely than this old favourite, and throughout winter it is one of the brightest things to be seen in the outdoor garden. As a rule a really good show of flowers is not obtained before Christmas, though a few may be open early in December. The mild weather experienced this autumn has, however, resulted in its being forced into bloom before its usual season, and now and for the past week it has made a very creditable display. Although usually grown on a wall, this is by no means necessary for its successful flowering, for if planted against a rough fence, old tree trunk, or against a group of rough tree branches, it makes a pretty informal mass, the long wand-like shoots smothered with golden blossoms arranging themselves in a free and graceful manner. Planted in company with Ivy, either on a wall or on a large tree root, it is also very pretty, the green leaves of the Ivy setting off the flowers. In some places it is used for hedges, and when left to ramble freely it looks very pretty, but these hedges are too often spoiled by being pruned late in the year, so shearing off most of the flowers. When any pruning is required it should be done immediately the flowers are over. This gives a good long growing season. W. D.

### AROMATIC SHRUBS.

**I** SPENT portions of February and March in the Riviera, but owing to illness I was unable to do much plant-hunting. During the time, however, I spent some days at Cap Martin, and as the hotel is in the very midst of the natural woods I was able to get some walks in them without fatigue. It would be hard to find more delightful woods; they go down to the sea, and walks have been

made through them, and the hotel proprietors have had the good taste to leave the woods as much as possible in their natural state. As I walked through them I was struck with the abundance of sweet-scented shrubs, the whole underwood being a mass of Myrtle, Rosemary, Pistacia, and Thyme, with a mixture of Rue. There were other sweet-scented plants, but these were the chief shrubs, and I noted many things in connexion with them which I think worth recording.

The shrubs I have named are well known, but each of them has a botanical and historical and literary interest. The five belong to different botanical families, but they have some rather curious points in common. They are all strictly southern plants, none of them being really wild north of the Alps. Rosemary has been reported from one place in Switzerland, but the botanists are agreed that it is an alien. They all, with the exception of Rosemary, bear their old Greek names, which they have carried with small changes into every country in Europe. The Greek name of Rosemary is not exactly certain; it was probably Libanotis, but it very early got the name of Rosmarinus, and is so named by Horace, Ovid, Virgil, and Pliny, and it carried the same name into every European country. The five are lovers of the sea, and while one shows it in the Rosmarinus, another of them brings to our memory Virgil's description "*amantes littora myrti*"; and though all southerners, they have all long been special favourites in English gardens, the Myrtle, Rue, Thyme, and Rosemary having been grown in England from the very earliest times, and the Pistacia was grown by Evelyn in the seventeenth century, and it was probably grown much before his day, as he speaks of it as a well-established shrub, and lays no claim to its introduction. And as a last point of resemblance they are all highly aromatic shrubs, so much so that if anyone was asked for an instance of an European aromatic shrub he would certainly name one or more of these, perhaps all; and that brings me to the proper subject of my paper.

I confine myself to the five shrubs I have named; and I said that each has its special botanical, literary, and historical interest. I must say a little on these points, but it must be very little. The Myrtle was a favourite both with the Greeks and Romans; with the Romans especially it was almost

MAGNOLIA GRANDIFLORA.

as great a favourite as the Rose; it was more abundant in Italy and Liguria than in Greece, and the best was said to come from Egypt. It is not found wild north of the Alps, and is never far removed from the sea, and it is very possible that this connexion with the sea may have been in Shakespeare's mind when he contrasted "the morning dew-drops on the Myrtle leaf to the great sea" ("Anthony and Cleopatra"), and in his time the Mediterranean was always known and spoken of as the great sea. The name and the plant very early came to England, and the name was soon transferred to the Gale or Bog Myrtle, with which, however, it has no connexion. The Rosemary has very much the same history, but was a greater favourite in English gardens than the Myrtle, because of its greater hardiness, and it very soon found its way into English literature. It had a great celebrity as a bee plant, and in the Riviera, as at Narbonne, it has the credit of giving a peculiar flavour to honey. The Rue, like the Myrtle and Rosemary, as an European plant is strictly Mediterranean, though it has become naturalised in several other parts. It was certainly in England in the eighth century, and was reckoned among the most valuable plants for medical purposes, but for all commercial purposes it has long been supplanted by its near relation the Orange; they both belong to the same natural family, the Rutaceae, but the Orange as a Riviera plant is the head of the family.—H. N. E., in *The Pilot*.

(To be continued.)

## CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

### THE FLORIST'S CARNATION AND PICOTEE.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—I was very pleased to read the remarks of the Rev. F. D. Horner; it reminded me of our discussions in the gardening Press a quarter of a century ago. The most redoubtable champion amongst us was Mr. E. S. Dodwell. One of Sir John Tenniel's most characteristic caricatures of the late Mr. W. E. Gladstone took the form of an exceedingly fierce rough terrier dog, with the motto, "Who said atrocities?" Such was our friend Mr. Dodwell when any one touched the Carnation not exactly to his mind. We all liked to read his remarks; and we are delighted with those of our friend Mr. Horner, although he has nothing of the rough terrier dog. I do not see where I am wrong, because both generically and specifically there is no difference between a Carnation and a Picotee; they both belong to the same genus, *Dianthus*, and also have the same specific form—*Caryophyllus*. Surely Mr. Horner will not contest this? They differ in the colour of the flowers, as I stated. Lower down Mr. Horner quotes me as stating that "really there is no difference between a Carnation and Picotee." If you separate a man's words from the context you may make him say almost anything you like. He omits "except in the colour of the flowers." Mr. Horner knows very well indeed that I know the Carnation and Picotee as well as he does; that many of the best Picotees, both yellow and white ground, were raised by me from seed. On December 12 one of the leading exhibitors was showing me his plants; he told me that Fortrose, a rose-edged Picotee, was the best in existence, and that he had won "premier" with it three or four times; moreover, it won "premier" for me when I first introduced it. In yellow ground Picotees my seedling, Mrs. Robert Sydenham, held the highest position for many years.

I have won many prizes for Carnations during my thirty years or more of exhibiting, but never was disqualified owing to my mistaking a Carnation for a Picotee. Even a "colt," as they designate young exhibitors in the North, never could make such a mistake. I have frequently described the difference between a Carnation and Picotee; but

the point seems to be, are they or are they not generically and specifically distinct? I maintain they are not. If my good friend maintains that they are specifically distinct, will he kindly let us know the two distinct species. The florist Carnation is marked with flakes and stripes on the petals, so was the Picotee for many years, but the old florists found chance flowers with the margins of the petals marked as well as the other part, and in the course of years (generations, in fact) they selected and selected until in white grounds we have Ganymede, Mrs. Gorton, Zerlina, Somerhill, Mrs. Sharpe, Fortrose, &c. In yellow grounds we have Childe Harold, Alcinous, Gertrude, Mrs. Walter Heriot, Othello, Lady St. Oswald, &c. I have sent up the names to the Editor all in their various classes. I thank Mr. Horner for all the useful information he has given us, and especially in his statement that the Picotee is prone to produce weak bars, streaks, and dots over the ground colour. Pray, my good sir, what is this but the Picotee harking back to its primal source? In my work of seedling raising (and I have raised thousands of Picotees from seed) I have raised scores of self-coloured Carnations directly from Picotee seed.

One of the best Picotees twenty-five years ago was Her Majesty. It has pure white flowers, with a very narrow margin of purple; this was carefully crossed with another Picotee of a similar character. This cross produced self-coloured Carnations, one of which was sent out as Purple Emperor. Surely, when self-coloured Carnations are raised directly from undoubted crosses of white ground Picotees nothing more is needed to prove their descent from one primal source. JAS. DOUGLAS.

### UNTRUSTWORTHY ADVICE.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—Most of those who study the Horticultural Press do so in order that they may learn, from the writings of acknowledged experts in the different sections of gardening, the correct treatment of their favourite subjects, the peculiarities and requirements of plants new to them which they may wish to possess, and the best methods of increasing the attractions of their gardens. The amateur generally believes implicitly in the reliability of the advice thus given, and with good reason, for the writers are, almost without exception, from their wide experience, well qualified to speak with authority upon the subjects of which they write. Occasionally, however, one chancance upon an instance where this reliability is conspicuous by its absence.

Such a case attracted my attention a few days ago while scanning the gardening column in a daily paper of wide circulation. The paragraph in question was devoted to wall plants, and lists were given of tender, half-hardy, and hardy subjects for covering walls. In the list of tender wall plants was included the absolutely hardy North American *Aristolochia Siphon*, also *Acacia affinis*, and *A. dealbata*, which two are held to be synonymous at Kew.

Among half-hardy wall plants the North American *Tecoma* (*Bignonia*) radicans, *Forsythia suspensa*, and *Jasminum nudiflorum* were named, all three of which are hardy, and *Berberidopsis corallina*, which bears glowing red flowers, was stated to produce "berries only." In the list of hardy wall plants were to be found *Carpenteria californica*, *Buddleia globosa*, *Benthamia fragifera*, and *Veronica*. None of these four can, I think, be termed absolutely hardy. I have seen a large shrubby *Veronica* growing at the foot of a wall killed in a severe winter, even in the south-west. *Benthamia fragifera* is certainly not hardy except in the south, and is no more fitted for a wall plant than is an Elm, for in a genial climate it becomes a forest tree 60 feet or more in height. *Heliotrope* is given as a half-hardy wall plant and classed with *Jasminum nudiflorum*, but is less hardy than any of those named in the list of tender wall plants, being susceptible to a few degrees of frost when not grown with other climbers that shelter it or given artificial protection. Such advice as this, if acted upon, would only lead to disappointment; but, happily, one does not meet with such

glaring misstatements in papers entirely devoted to gardening interests. S. W. FITZHERBERT.

[We quite agree with our correspondent. The horticultural contributions to the general Press are generally so inaccurate that we fear those who act upon the advice go sadly astray.—Ed.]

## THE KITCHEN GARDEN.

### EARLY BROAD BEANS UNDER GLASS.

BROAD BEANS are not great favourites in many houses, and this may be owing to various causes. The pods are too large, the seeds too old, and the flavour harsh. These objections do not apply to Broad Beans sown at this season either in pots, boxes, or frames, and finished in the open. Grown thus, and if the pods are gathered young, the Beans when cooked are equal to Marrow Peas. The latter may be thought a strong assertion, but it is true. Many may think it out of place to give glass culture to this vegetable, but this is not so. We often bestow more labour upon vegetables of less value. The Broad Bean is of better quality in May and early June than in July and August. To get an early crop I would advise sowing now, and give cold frame culture for the next two or three months, say till the end of February. Frames may not be available. Many shifts may be made, but by the term sown under glass, I mean where protection may be given for a time, so that such structures as cool fruit houses, Peach cases, or anywhere giving shelter, and when the plants can be grown near the light. I prefer frames if they can be spared, as the plants can be grown near the glass and given plenty of air in suitable weather. The old system of sowing Beans in November is not practised much now, and it has little to commend it as the results were so uncertain, and I do not advise sowing in heat. I have seen the seeds sown much later and germinated in a warm house, but it weakens the plants. It is far better to sow much earlier and give a longer season's growth without heat at all. When sown in pots, I prefer a good-sized pot—5 inches or 6 inches—and four seeds in the smaller size named. If sown thicker, early thinning should be resorted to.

Beans like a good holding soil, but the top soil should not be too heavy at this season of the year. We use a liberal quantity of wood ashes with heavy loam, and this promotes a sturdy growth. Seed may also be sown in boxes, and these plants, when large enough, are carefully lifted with a ball. Pots are much the best, as here the mass of earth and roots is intact. The plants are housed till the weather is suitable for planting out, which depends upon the season, but plants not given any heat are much harder than those raised otherwise, and they do not flag or feel cold winds if well moulded up at the time of planting. Plants sown under glass are much dwarfer than when grown in the ordinary way, so that it will repay the cultivator to reserve a warm corner for this crop. The rows may be much closer (15 inches to 18 inches), but the plants should nearly touch in the row, so that no space is lost. At planting each lot should be made firm, and they do best in a deep drill, but the soil should be made rich and be prepared some time in advance of the planting, so that any food placed in the soil is in good condition for the roots to lay hold of.

A south border will be a good place, and it is surprising what a quantity of pods plants raised thus will give, and some weeks in advance of the seeds sown in the open. The Bean is usually a long time germinating in cold soil. As regards varieties, I like the medium long green pods best. I do not think the very long podded sorts are so good. By this, I mean such as the Mammoth varieties, the small section of which—the Early Mazagan, Beck's, and Dwarf Green—are liked by many, but I prefer the ones named. If the plants are kept dwarf, almost any of the early varieties may be relied upon. Much depends upon the soil and culture given. G. WYTHES.

WINTER CUCUMBERS.

VARIOUS notes upon the important crop of winter Cucumbers have recently appeared in THE GARDEN. As all growers know, a good deal of skill and close attention are necessary to obtain a fair crop of Cucumbers during the winter months, and especially in the neighbourhood of large towns, where the atmosphere is impure. Keeping the growths fairly thin, so as to admit as much light and air as possible, taking care not to crop the plants very heavily at once, but endeavouring rather to keep them in moderate bearing for a considerable time, adding fresh light soil as new roots appear, careful watering, a moderately moist atmosphere, and preventing the formation of seed are the chief objects to have in view to keep winter Cucumbers in good health.

GARDENING OF THE WEEK.

KITCHEN GARDEN.

**W**HILE the gardener's life is one of continual forecasting, this is the season when he might with profit indulge in a retrospect of the year that has passed. During that period many alterations and improvements will have been thought of. This is the season when any change in the plan of cropping or style of garden can be best carried out before the rush of spring work comes on. The new year bids fair to open with fine weather, permitting digging and trenching operations to be pushed forward. All vacant plots should be trenched or dug as soon as possible. Where it is intended to grow Onions the ground should be deeply trenched and a liberal supply of well-decayed manure dug in. A good dressing of soot scattered on the ground before trenching, and a slight one after that operation, will benefit this important crop. Borders with a southern aspect should receive immediate attention and the ground prepared for the first seed sowing. For the earliest Peas trenches about 18 inches deep should be thrown out the full width of the border and some well-decayed manure placed in the bottom, or, as some growers prefer, leaf-mould. The soil should then be turned back, and the trenches so treated marked with a short stake at each end.

SEAKALE.

Pots may be placed over crowns in the open and the whole covered over with rough well-fermented manure and leaves. A supply should also be lifted for forcing in the Mushroom house, this, according to requirements, to be repeated every third week.

ASPARAGUS.

Where this vegetable is in demand it may now be forced with ease either in the Mushroom house or on hot-beds. See that the crowns are at least three years old. If grown on hot-beds place about 3 inches of soil on top of the heating material for the crowns to rest on; give the crowns a covering of about 5 inches of light soil. Airing on all favourable occasions must be carefully attended to.

Take every advantage of dry or frosty weather to collect and burn all garden refuse. Inspect stock of Pea and other stakes. Place manure on all ground still to be dug. THOMAS HAY.  
*Hopetoun House Gardens, Queensferry, N.B.*

INDOOR GARDEN.

FIRST review the temperatures of all plant houses and ascertain whether for the time being they are too high or too low, as an undue degree of heat in either respect is productive only of disappointment. A too high temperature at this early season is obnoxious even to exotics, for they are forced into

an unnatural effort to make growth, with the result that they soon become attacked by thrips, aphid, &c. A night temperature of 60°, with a rise of 5° during the day by artificial aid, is high enough for the East Indian Orchid house, whilst the plant stove may fall as low as 55° at night and rise to 60° in the daytime. Begonia Gloire de Lorraine will flower satisfactorily in a night temperature of 50°, with a rise of 5° during the day. The greenhouse, in which usually there is a varied collection of plants, should have a night temperature of 45°, the temperature during the day being regulated according to circumstances.

TREE CARNATIONS

will do well in a temperature of 50° at night and 55° during the day, but that for Malmaison Carnations may fall to 45° at night, and should not be higher than 50° during the daytime. Give air on all favourable occasions to the occupants of the two last-mentioned houses. A thorough cleansing of the plants from insect pests, as well as the interior of the houses in which they are situated, at this time of the year is of paramount importance. Wash well the woodwork, glass, and walls of the structures with hot water and soft soap, and

light. Plunge the latter in a gentle bottom-heat at first with an atmospheric temperature of 65° to 70°, raising it to 80° as growth advances. Retarded crowns may be started in a cool, close frame, and afterwards be removed to a light, airy position on the greenhouse shelf. J. P. LEADBETTER.  
*The Gardens, Tramby Croft, Hull.*

FRUIT GARDEN.

FRUITING PINES.

To provide a supply of ripe fruit in May and June no time should now be lost in getting the Pine stove ready for the earliest Queen plants. Thoroughly wash and paint the pit if necessary, remove all dirt from the tan or leaves, and add fresh material to produce the bottom-heat required; this should range from 85° to 90°, if it exceeds the latter the pots should be shaken a little to allow the heat to escape by the sides of the pots. Where hot-water pipes are used a steady bottom-heat is more easily maintained. When the bed is ready for the plants, select the Queens which are thickest at the collar and open in the centre, as these are most likely to show fruit before making fresh growth. Remove a few of the short lower

A HOUSE OF WINTER CUCUMBERS IN A MARKET NURSERY.

finally, directly the walls are dry, coat them with lime-wash. To provide

CUT FLOWERS

bring into heat in batches to suit requirements early Roman and Italian Hyacinths, Paper White, double Roman, and Snowflake Polyanthus Narcissi, with the old double Daffodil (*N. Telemonius plenus*), *N. princeps*, Freesias, Snowdrops, Crocuses, Chionodoxas, Tuberoses, and single Duc Van Thel Tulips. A vinery that is just started is a capital place in which to introduce an early batch of *Rhododendron præcox*, an old but too rarely grown plant; *Azalea mollis*, *Spiræa confusa*, Lilacs Charles X. and alba virginialis, *Staphylea colchica*, the pink-flowered *Prunus triloba*, *Azalea Deutsche Perle*, *Deutzias*, *Choisya ternata*, *Spiræa astilboides*, Solomon's Seal, and *Delytra spectabilis*. The forcing—if it may be called such—of

LILIES OF THE VALLEY

has become an all-the-year-round duty, for between retarded and ordinary crowns they can be had in flower every day in the year. The crowns, whether retarded or not, must be covered lightly over with loose Moss to keep them moist and to subdue the

leaves from the stems and any loose soil: top-dress with rough fibrous loam, adding a little bone-meal and soot; it must be firmly rammed round the bases of the plants. Plunge the plants about 2 feet apart and water thoroughly with clear water. Keep a moderately moist atmosphere by damping the paths and walls and filling the evaporating pans. Water may now be sprinkled on the surface of the beds on bright days only. Maintain a night temperature of 65°: on sunny days the maximum may reach 80°, a little air being given at 75°. Close early, and get all the assistance possible from the sun.

SUCCESSION PLANTS

must be kept in a steady bottom-heat of 70° to 75°. They must not be allowed to get dry at the roots or they are sure to show fruits when the temperature is raised. The treatment of later plants is the same as that already recommended.

WINTER CUCUMBERS.

Owing to an insufficiency of light and an excess of moisture these have required much care and attention. A thin mulchiog with rich soil (and a little Thompson's Manure added) to plants which

have been fruiting some time will be of great assistance. Remove any old growths, and introduce young shoots from as near the base as possible and keep the crop down to a reasonable limit. Seeds should now be sown of Improved Telegraph or some other approved variety, one or two seeds in a 3-inch pot and plunged in a bottom-heat of 75°. When the seedlings are well through the soil place them nearer the glass. Make up a bed of fresh leaves and place mounds of soil about 3 feet apart. Plant out the seedlings when they have made three leaves and encourage a vigorous growth. Pinch the growths but little, keep a night temperature of 68°, and maintain a moist atmosphere. F. JORDAN.

*Impney Gardens, Droitwich.*

## ORCHIDS.

In commencing this series of notes on work in the Orchid houses, it is my intention to write precisely what we are practising at Gatton. Although the methods now adopted are so contrary to those advocated a short time ago, I shall write with every confidence that growers who will break away from the old-fashioned methods will soon see a marked improvement in their plants. The new style of potting, like all other new introductions, will not find favour with some. They will prefer to continue in the way we were all following a few years ago. I have no hesitation in saying that there will be very few of that class left in the course of another year or so. Many Orchids that were supposed to live for a few years after being imported to this country are now being made to grow freely, such as *Oncidium varicosum* Rogersi, *O. lanceanum*, and *O. tigrinum* that were fast dying under the old methods, have been given fresh life and made to produce fine bulbs and leaves, and carry fine spikes of flowers since they were treated differently.

Such cases as those where sadly deteriorated Orchids have been restored to health and vigour are convincing proof of the desirability of changing from the old method to the new before one's plants have begun to deteriorate. I shall from time to time as the seasons for repotting come round give the form of compost, and the advantages gained by cutting away useless back pseudo-bulbs when repotting, and the importance of using a natural drainage. We have found a very great improvement in our plants since we gave up the old method of potting, they have stouter bulbs, leaves of greater substance, and consequently the flowering season does not reduce the vitality of the plants to anything like such a degree as was the case in the past.

### PREPARATION FOR POTTING.

All should see that they have in stock good fibrous peat, loam, sufficient sphagnum moss to last till April, some good Oak leaves (1902) that have not been subjected to fermentation, and a fair quantity of thoroughly sterilised rhizomes that have been taken from the peat; it is of great importance to ensure thorough sterilisation of the rhizomes, otherwise harm instead of good may accrue from their use. I am convinced that these rhizomes, which have been so freely thrown away in the past, will play a most important part in Orchid culture in the future.

Although this is only the first week in the new year the time for repotting or resurfacing will soon be here. Valuable time is often lost through having to wait for this or that material, and often the roots are too far advanced for repotting to be done without injuring them. W. P. BOUND.

*Gatton Park Gardens, Reigate.*

## FLOWER GARDEN.

### WALL PLANTS.

THE recent rough winds will probably have detached some branches of climbers and other shrubs trained against walls. Soon after the winds have abated these plants should be looked over and all loosened shoots made secure. In the case of high walls and dwelling-houses it is not wise to attempt any ladder work while the wind is blowing, as it frequently has a nasty habit of

curling around corners in a dangerous manner. *Chimonanthus fragrans* and *Jasminum nudiflorum* will now be opening their earliest buds, and if bad weather is anticipated some protection should be afforded. For this purpose fronds of Bracken are most useful, or sprays of *Quercus Ilex* and short branches of the common Silver Fir. If required for house decoration branches of the Jasmine cut and opened in water in a warm house will be found to be of a better colour than when cut direct from the plant. The Winter Sweet also opens well in water. Single flowers floated in finger bowls or small glasses are delightful; the warmth of the room draws out the fragrance surprisingly.

### LAWNS.

As often as time and weather permit the lawns should be well swept when necessary and rolled. Worm casts are not nearly so troublesome as they were a month or so ago. If there are any bare or rusty-looking patches, and it is not desirable or convenient to relay turf, a sprinkling of any approved artificial manure will speedily improve the appearance of the grass. If the manure is mixed with twice or three times its bulk of fine dry soil or dry sand it can be spread more evenly. Except in a few favoured localities, it has of late been much too wet to attempt such work as relaying turf, but advantage should be taken of any spell of dry and mild weather to complete this work before the year is far advanced.

### SNOW.

When the workmen live at any distance from the gardens they should be given to understand that in the event of a fall of snow on any Saturday evening or Sunday morning they are expected to come on the Sunday and do such necessary work as clearing paths and shaking the snow from young conifers and any other evergreen trees and shrubs which are likely to be broken by the weight of snow. A supply of long poles should be kept in a convenient place. If any branches are broken off the wound on the tree should be made smooth and coated with tar, thick paint, or any approved mixture to prevent the ingress of moisture or microbes.

### EMPTY VASES.

After heavy rains all empty vases standing out of doors should be examined to see that the drainage holes are clear, otherwise water will collect which if frozen would probably burst the vases. Two or three fallen leaves are often sufficient to stop the free passage of rain water.

A. C. BARTLETT.

*Pencarrow Gardens, Bodmin.*

[Readers in the Midland and Northern Counties need not fear to follow the advice given by Mr. Bartlett, for Pencarrow Gardens are in the north of Cornwall, where the cold is often most severe. —ED.]

## CHRYSANTHEMUMS.

IN spite of all that has been said to the contrary as to the Chrysanthemum not being as popular as it was a few years since, there is not the slightest doubt that it still retains its exalted position as the Queen of Autumn flowers, and so long as novelties of the various sections are annually introduced, so long will the public taste be gratified. The great diversity of form and colouring creates fresh enthusiasm, and though some regard the large, massive flowers as worthless, the great majority see much to admire in them.

### PROPAGATION.

Ultimate success so much depends on a good start being made that too much care can hardly be bestowed on the propagation and selection of cuttings. The first week in the new year will be quite early enough to begin striking the cuttings to produce exhibition flowers by November next, providing the old stools have been properly treated, as by that time the shoots should be clean and sturdy. The soil, which should be got in readiness and thoroughly mixed a few days before it is used, must be of a fairly light, porous nature. Light, fibrous loam and well-decayed leaf-soil in equal parts, with a plentiful supply of coarse

silver sand, will make a suitable mixture, care being taken to have it in a nice workable condition, *i.e.*, neither too wet nor too dry. The cuttings should be inserted singly in 2½-inch pots, which should be thoroughly cleansed, and well drained by placing one inverted crock over the hole, covering this with very finely broken pieces, over which should be placed a little fibre, free from soil, taken from the loam heap. Ensure the compost not becoming mixed and clogging the waterway. As I have often pointed out, this is of the utmost importance when potting Chrysanthemums in every stage. The soil should be pressed in moderately firm, and the surface covered with a little silver sand before inserting the cuttings. Small frames or hand-lights are well suited for rooting them, and these should be placed on the stages, either in an earlyinery, orchard, or greenhouse, and three-parts filled with Cocoanut refuse, when the cuttings may be attended to with ease and comfort, whatever the conditions of the weather outside.

Before taking off the cuttings thoroughly fumigate the plants to ensure freedom from insect pests. Choose the strongest, short-jointed growths, selecting, as far as possible, root-suckers, as these are less liable to produce premature buds. Prepare the cuttings in the ordinary way, which should be about 3 inches in length. Do not take off more at the time than can be speedily put in, never allowing the foliage to flag. Each cutting should be correctly labelled as it is put in, thoroughly water in, and keep close for a few days. These will probably require to be damped over daily in early morning, but at the same time this should not be done so as to cause the foliage to damp. It may be necessary in very dull weather to remove the lights for an hour or so during the morning. Immediately the cuttings begin to push forth young roots the lights should be carefully opened, and if this is done the young plants will quickly gain strength. Undue forcing in the early stages of their growth should be rigorously avoided, and every encouragement be given to induce the growths to be made in as natural a manner as possible, and this can only be assured by assigning to them a cool, light, and airy position, such as shelves near the glass, after the pots become filled with roots. An up-to-date collection can only be maintained by adding annually a few of the best novelties and excluding some of the older ones, which are played out and superseded by others. It is yet full early to propagate Pompons and general decorative varieties; but the old plants which are required for stock should be well treated, and arranged either in cold frames or cool houses to ensure a plentiful supply of free healthy cuttings later on.

### LATE-FLOWERING VARIETIES

have done remarkably well this season, and many which were specially treated to flower now are giving a wealth of blossom which is simply invaluable in every establishment where cut flowers are in demand. Never allow these to become infested with green fly, and to assist the blooms to develop properly frequent doses of manure water should be given. E. BECKETT.

*Aldenham House Gardens, Elstree, Herts.*

## THE FRUIT GARDEN.

### FRUIT TREE PRUNING.

THE old story of the man and the ass perpetually "renews its youth like an eagle," at least as far as the tending of contending advice goes. Here we have in the last number of THE GARDEN Mr. Tallack sitting on Mr. Owen Thomas. It is to be hoped he will not find it a prickly seat as in the case of

"The old idiot whose folly  
Induced him to sit on a Holly."

Joking apart, the question is really a very important one. There is hardly a more important crop than that of Apples, and it is of the keenest interest how best that crop is to be secured. Mr. Tallack has noticed that I expressed my intention of following the advice of Mr. Thomas, though

somewhat unwillingly, as my own experience ran rather counter to it, but my modesty led me to think he was more likely to be right than I was. I also said it would be extremely desirable to have the question ventilated and dealt with by the most experienced Apple growers in the kingdom. Mr. Tallack is the only one who has responded, and that only *longo intervallo*, and I therefore now call upon the editor to endeavour personally to elicit such an opinion. No more interesting subject can occupy his pages.

While on this subject I wish to bear my testimony to the value of Mr. Petts' articles in some late issues. A book on pomology dealing exhaustively on the subjects, on which he of course merely touches the fringe, is much needed, and would be of great practical use. Amateurs as a rule know very little about the Apples they ought to plant. If in the book I suggest—and perhaps Mr. Petts might take up the idea—there were, say, 100 of the best Apples treated of—soil, climate, and requirements all taken into the fullest examination—hundreds of purchasers would know what to do instead of groping blindly in the darkness as they do now. I suppose, as he says, there is no absolutely perfect Apple. Were I to be called on to name the variety which comes nearest to it I would say Bismarck, a great cropper, a splendid grower, a most hardy variety, a very handsome, well-shaped fruit, and possessing Mr. Petts' favourite quality of weight. If some hybridiser were to produce a Bismarck keeping till June he would deserve an Olympian crown.

County Cavan.

D. K.

ROOT PRUNING FRUIT TREES.

It is not unusual for those who purchase trees to complain after a few years that, though the trees have grown nicely, they have failed to produce fruit. When a tree is of sufficient size to bear, and shows no disposition to do it, root pruning will cause it to bear. Many will prefer to wait a few years more rather than check a tree's growth by root pruning it, but others are too impatient to wait. It is on record here that a nurseryman had to "put the law" on a customer who refused to pay for Pear trees furnished because there was no "fruit on them within two or three years," which statement made to him at the time of purchase led him to take the trees, he averred. He lost his case, however, the nurseryman properly contending payment was due when the trees were delivered, and that the statement that the trees would bear in two or three years was but an opinion solicited and given without charge, and had nothing to do with the sale of the trees. This man was certainly in a hurry did he look for much fruit in that time, but it is not at all uncommon for Bartlett Pears to bear in a year or two from planting, and every year thereafter. Customers who may wish to do it may safely root prune their trees to promote fruitfulness. The practice is to dig a trench around the tree a few feet from the trunk and sever all the very large roots met with, or a goodly portion of them at least. This, if done in spring, will surely cause fruit-buds to set, to give flowers the following season. It could be done at any time between now and spring. This root pruning practice is but the following out of what all florists and gardeners know, viz., that a potbound plant will flower before one that is not potbound. It is the check to growth that causes the formation of flower-buds in both cases.

JOSEPH MEEHAN, in *The Florists' Exchange*.

SEEDLING APPLES.

AMATEUR gardeners may be better employed than in raising Apples from seed with a view to securing new varieties. Not only have they to wait some years before they see any results, but too often they are not judges of the merits of any seedlings they may raise. Again, it is found that any true line as to the merits of any seedling fruit cannot be obtained from a pure seedling tree. All fruits that are put into commerce have of necessity to be worked on stocks either by budding or grafting, and it is only when so worked and grown for a few years that a true test of the merits of a fruit can

be formed as to quality, cropping, keeping, &c. But really few persons—except they have special facilities for such purpose or are growers on a large scale—know of the qualities of the many named Apples we have. Many new ones are from time to time being put into commerce, but it is doubtful whether one now excels in any way varieties of from twelve to twenty years old. A. D.

PLANTING RASPBERRIES.

THE earlier this is done the better, so that the canes may form new fibres before the soil loses what little warmth it may have accumulated during the past disappointing summer. It is usual after planting to put a mulch of strong manure round them, which serves the double purpose of lessening the severity of the frost upon the new and tender rootlets, and of preserving the moisture in the surface soil the following summer, the Raspberry, when it is doing well, making a mass of surface-feeding fibrous roots. I made a Raspberry plantation in the autumn of 1902, and my experience may serve as a warning to some others. I got them in early and mulched them, cutting down the canes in March to about 9 inches in length. I was expecting good strong suckers to come up from the ground for next year's fruiting, and, after waiting a long time, I removed the mulch around some and found that the slugs had devoured some of the young shoots entirely, whilst others were being nibbled as fast as they grew. The mulch had served as a harbour for the slugs, which were very destructive after the wet summer of 1902, which was followed by an almost total absence of sharp frost in the winter. The result of my giving the slugs this protection was that of some three dozen canes put in only four or five have made good fruiting canes for next year, another eight or ten have just a feeble growth and are probably worthless, while the remainder are quite dead. *Experientia docet*. Slugs are more plentiful than ever this year, and the cold summer may be followed, as used to be the tradition, by a very sharp winter. When I plant the new canes I shall mulch them as before; but as soon as March comes the mulching will be taken away and buried in some deep trench, slugs and all, while some soot will be sprinkled round the canes to destroy any slugs remaining. A. PETTS.

NOTES FROM THE MARKETS.

COVENT GARDEN MARKET.

DECEMBER 22.—This was a very busy morning, there being a large trade in pot plants. Some complaints were made that cut bloom was not going so well as might be expected, but I found there was a general advance in prices. The supplies in all directions were good. Of pot plants Azaleas are now coming in, and are very good. Genistas were well flowered. A good supply of Begonia Gloire de Lorraine and Turnford Hall was seen. Hyacinths are hardly of first quality yet. Marguerites continue to be plentiful, also Chrysanthemums, but higher prices are now asked. Poinsettias were seen in abundance, and many of them were very good. The trade for Ferns and Palms appeared to be more brisk this morning, though the supply would exceed the demand considerably. Heaths were going out well. E. hyemalis is still very plentiful.

*Cut flowers*.—It would be difficult to give prices, but I found there was a general advance. *Lilium longiflorum*, which were quoted on Saturday at 6s., had gone up to 8s., and some salesmen were asking even more than this. Callas had also advanced at the same rate. Some very good English forced Lilac was seen. Eucharis, Tuberoses, Gardenias, Lily of the Valley, and Roses seemed plentiful, but there were very few Carnations after early morning. In Chrysanthemums the bronze, red, and yellow made higher prices than white, though the best quality whites were selling well. There were

plenty of Violets. Altogether the market was well supplied, and trade seemed likely to be very brisk. A. HEMSLEY.

KEW NOTES.

INTERESTING PLANTS IN FLOWER.

Temperate House.

ACACIA LINIFOLIA, A. platyptera, A. suaveolens, Chrysanthemum decaisneanum var. setumense, C. marginatum, Hibbertia dentata, and H. perfoliata.

Orchid Houses.

Erides Roebelenii, Angræcum pellucidum, Bulbophyllum auricomum, B. Pechei, B. strongylanthum, Calanthe microglossa, Catasetum splendens, C. tridentatum, Epidendrum chioneum, E. elegans, E. ramosum, E. Wallisii, Lælia albida, L. autumnalis, Listrostachys humata, Masdevallia melanopus, M. tovarensis, Maxillaria punctata, Odontoglossum maculatum var. downianum, Oncidium ornithorhynchum, O. varicosum, Platyclinis cucumerina, P. rufa, Pleurothallis pachyglossa, Restrepia striata, and Sarcanthus secundus.

T Range.

Aphelandra nitens, Barleria flava, Eranthemum tuberculatum, Ipomœa Maboni, Jacobinia chryso-stephana, J. ghiesbreghtiana, Jasminum gracillimum, Lachenalia pendula, Lindenbergia gaadiflora, Plectranthus crassus, P. chiradzulensis, Tillandsia Lindenii, and Vellozia equisetoides var. trichophylla.

Greenhouse.

Carnations in variety, Chrysanthemums, Epacris and Ericas in variety, Geraniums, Lily of the Valley, Narcissus (Paper White), Roman Hyacinths, Tulips, Peristrophe speciosa, Senecio grandifolius, and many other things.

THE EDITOR'S TABLE.

WE invite our readers to send us anything of special beauty and interest for our table, as by this means many rare and interesting plants become more widely known. We hope, too, that a short cultural note will accompany the flower so as to make a notice of it more instructive to those who may wish to grow it. We welcome anything from the garden, whether fruit, tree, shrub, Orchid, or hardy flower, and they should be addressed to The Editor, 5, Southampton Street, Strand, London.

A CHRISTMAS GATHERING OF FLOWERS FROM DEVONSHIRE.

Mr. S. W. Fitzherbert sends for our table the following flowers from the open garden:—

Jasminum nudiflorum	Agathaea celestis
Pentstemons	Scented-leaved Pelargoniums
Scabiosa caucasica	Rose Marie Van Houtte
Pittosporum Tobira (very sweet)	Calceolaria Burbidgei
Cosmos bipinnatus	Lithospermum prostratum
Christmas Rose	Cyclamen Comi
Pink and White Valerian (Centranthus ruher)	Cytisus racemosus
Solanum jasminoides	Iris stylosa
Achillea umbellata	Zonal Pelargoniums
Campanula muralis (portenschlagiana) major	Mesembryanthemums in many colours
Chianthus puniceus	Erigeron micronatus
White Paris Daisy (Chrysanthemum frutescens)	Monthly Rose
Enothera Youngi	Habea suaveolens
Ivy-leaved Pelargonium (Mme. Crousse)	Eupatorium weinmannianum
Schizostylis coccinea	Winter Heliotrope (Tussilago fragrans)
Annual Antirrhinum	Polyantus Narcissus
Convolvulus Cneorum	Shrubby Veronicas
	Escallonia montevidensis

ST. BRIGID ANEMONES AT CHRISTMAS.

Messrs. Gilbert and Son, Anemone Nurseries, Dyke Bourne, sent a boxful of their beautiful St. Brigid Anemones with foliage, all gathered from the open ground. We have recently described the warm and varied colourings of the flowers, and

our correspondents write that the Anemone beds "look as though it were April, rather than December."

#### LATE CHRYSANTHEMUMS.

Mr. George Ellwood sends from the Swanmore Park Gardens, Bishops Waltham, a few flowers of the principal late-flowering varieties to show their great value at this season. Their names are familiar, but those who do not know the varieties should make their acquaintance if a wealth of graceful flowers is desired in midwinter. Mrs. W. A. Weeks, Princess Victoria, King of the Plumes, Pink Princess Victoria, L. Canning, Annie Heard, Duchess of Edinburgh, Golden Princess Victoria, and The Queen. Also Persian Cyclamen flowers representing an excellent strain. Mr. Ellwood recommends slitting the stem in an upward direction to keep the flowers fresh as long as possible.

## OBITUARY.

### THOMAS W. WEATHERED.

THOMAS W. WEATHERED, who died December 4, was born in Stockport, Cheshire, England, on August 3, 1819. He came to the United States in 1840 and took a position as superintendent for R. H. Hoe, Esq., in New York City. In 1849 he associated himself with Anthony Hitchings in the business of greenhouse heating in Crosby Street. In 1859 he formed a partnership with E. Cherevoy, and the Weathered and Cherevoy hot water boilers soon took a high place in the esteem of greenhouse men. Mr. Cherevoy died in 1870, and Mr. Weathered continued the business until 1888, when he retired, leaving it to be conducted by his sons. Mr. Weathered was a great traveller. He went to California gold hunting with the famous "49ers," and it has been his custom annually up to the present year to make a pilgrimage to his old home in England. In business affairs he was the soul of honour and uprightness. Socially he was cheery and companionable and his disposition was kindly and considerate. Of a large family of children two sons and one daughter survive, the elder son being C. B. Weathered, the treasurer of the New York Florists' Club.—*American Florist.*

### MME. EDOUARD ANDRÉ.

We much regret to learn that Mme. André, wife of M. Edouard André, the widely known French horticulturist, died suddenly in Paris early in December. M. André will have the sympathy of his numerous English friends.

### JOHANN OBRIST.

A LARGE train of sympathising followers attended the burial of Herr Johann Obrist, head gardener of the Royal Botanical Gardens at Munich, medallist of the Order of Merit of the Bavarian Crown, whose mortal remains were laid to rest on December 19. After the burial service, Professor Dr. K. Göbel, Director of the Royal Botanical Gardens, gave an address, and in the name of all the officials and employes of the botanical gardens deposited a beautiful wreath at the grave. Professor Göbel pointed out how much the institution had been indebted to this thoroughly competent official, whose death had taken away all too early from the arduous duties (Obrist was only forty-nine years old) to which he had always attended with rare energy. From early youth, Professor Göbel continued, Obrist had been an enthusiastic admirer of the alpine flora, and had in this sphere gained a most extensive knowledge and an amount of experience, both of which many a learned scientist might well have envied him. His pet child was the Alpine garden, which was established a few years ago on Mount "Schachen" in the Wettersteiner range of the Bavarian highlands, and which he knew how to tend with the greatest care and self-sacrifice. As a token of recognition for the valuable services rendered there, for which it would be most

difficult to find an official substitute, the speaker was commissioned to lay down a wreath in the name of the "Society for the Protection and Care of the Alpine Flora." Among the other numerous floral tokens of sympathy was also a wreath from the Bavarian Horticultural Society of Munich, of which the deceased was a member. Herr Obrist in his younger days had the advantage of having served for eight years partly at Innsbruck and partly at Vienna under that celebrated botanist Professor V. Kerner, by whose directions he spent three summers on Mount Blaser, near Innsbruck, at a height of 7,000 feet, in a hut expressly constructed for the purpose. There he experienced many an adventure and gained information which came useful to him in his practical work in after life. His name is well known as a collector of alpine plants, and also as a fellow worker in that laborious and excellent publication "Max Kolb, Die europäischen und überseeischen Alpenpflanzen. Stuttgart, Eupen Ulmer, 1890."

### J. H. FITT.

It is with much regret that we have to record the decease, after a long and painful illness, of Mr. J. H. Fitt, at Welwyn, Herts, at the age of seventy-three, he having been born at the same place on November 1, 1830. For no less than fifty-four years he had charge of the Frythe Gardens at Welwyn, after commencing his career as a gardener at Stagenoe Park, whence he went to Bayford Bury, Hertford, to the famous gardens of Mr. Baker, subsequently serving under Messrs. Paul, of Cheshunt, up to the time of his long engagement at the Frythe. For some years, until his illness incapacitated him, he formed one of the Royal Horticultural Society's floral committee, where his kindly face will be much missed. Combined with a thorough knowledge of horticulture in all its branches, was a special acquaintance with our native Ferns, of which he had a large and choice collection, and in this particular cult he will be equally missed by a host of sympathetic friends.

## SOCIETIES.

### CROYDON HORTICULTURAL SOCIETY.

THE last of the series of lectures arranged for 1903 was given at the society's rooms, Sunflower Temperance Hotel, on the 15th ult., when, before a good attendance of members, Mr. J. Gregory of Croydon, in a very descriptive and interesting manner, delivered a lecture on "Some Gardens I have Visited," illustrating it with lantern slides, prepared by him from photographs taken by himself from time to time during his long career in the horticultural world, and truly many of them reflected great credit on his endeavours as a photographer and slide maker. Mr. Gregory was one of the chief promoters of this society, and his energies, displayed at all times for the well-being of this excellent institution, are widely known. He started with a few notable features found in gardens in the immediate neighbourhood of Croydon, some of them dating back years ago, before the builders' hands had split them up, and those which now stand out prominently in this town, and are recognised to be types of beauty. Following on with ample illustrations, he showed the grandness of those beautiful gardens found in and around London, such as Holland House, Gunnersbury, &c., afterwards extending to the more distant radius of Friar Park, Henley-on-Thames, where everything that man's hands can do in assisting Nature is exemplified. Many parts of Northamptonshire, such as the ancient Holmby House, made memorable by history of the Cromwellian period, were dwelt upon. Several views of this historical residence, also of Hazelbeach Hall, where, latterly, the lecturer was head gardener, were much appreciated, especially those depicting the stately trees with branches weighed down by a heavy fall of snow that occurred in May, 1891, and he remarked how the photographs were taken at four o'clock in the morning. For an hour and a half he entertained his audience with a pleasant discourse, which called forth warm and hearty applause at its conclusion. The thanks of the meeting were also conveyed to Mr. J. H. Baldoek of Croydon, who on this and several previous occasions has kindly placed his services, with the lantern, at the disposal of the society.

### READING AND DISTRICT ROSE SOCIETY.

THE first annual meeting of this society was held in the Mayor's parlour of the Town Hall on the 12th ult., Mrs. Benyon, Englefield House, Reading (the president of the society), occupying the chair, and there was a good attendance of members. Mr. W. L. Walker, the hon. secretary and treasurer, presented a satisfactory report and balance sheet, the latter showing an amount of £11 to be carried over to next year's credit. Mrs. Benyon was unanimously

re-elected as president, and Mr. W. L. Walker as hon. secretary and treasurer, and the committee appointed is a strong one from the rosarian's point of view. Mr. J. T. Strange, Aldermaston, Reading, is a well-known rosarian, and among those having seats on the committee are such successful cultivators and exhibitors of the Rose as the Revs. F. Page-Roberts, Allan Cheales, and C. S. Turner, with Messrs. R. C. Mount, Rigz, Dunlop, and Ashby. The date of the show in 1904 was fixed for July 13, to take place in the Abbey Ruins, Reading, which is the spot where the southern section of the National Rose Society held such a successful exhibition in 1896. It may be of interest to many to know that this portion of the ruins was formerly the banquetting hall of the monks of Reading Abbey, and it constitutes a unique site for an exhibition of this character.

### SHERBORNE GARDENERS' SOCIETY.

THE monthly meeting was held recently at St. John's Hall, under the presidency of Mr. John Dean. Mr. James Crook, of Forde Abbey, near Chard, gave a highly interesting and instructive paper on "The Progress of Horticulture." Mr. Crook also drew attention to the advantages of joining the Royal Benevolent Institution for the Relief of Aged and Distressed Gardeners, and to the Society for Assisting Gardeners' Orphans. The matter was discussed, and it was decided that the committee should go into the question, and lay full particulars before the next meeting. A hearty vote of thanks was passed to Mr. Crook for his paper, on the motion of Mr. Lane.

### IPSWICH GARDENERS' SOCIETY.

ON Thursday, the 17th ult., Mr. Richard Dean, V.M.H., read a paper, prepared by request, before the members of the above society on "The Carnation: Its History, Types, and Culture." Mr. E. Notcutt, the president, occupying the chair, the company being large. The leading points of its history were briefly touched upon; its development was dealt with more largely. Mr. Dean said that in reference to what is known as the florist's Carnation there are two distinct types of flower intimately related to each other, for they are simply two forms of the same subject—the Carnation and the Picotee, the former of which is placed by the florist into distinct divisions, viz., bizarres and flakes. In the estimation of the florist the bizarre stands higher than the flaked flower. The bizarre Carnations are placed under three classes: The scarlet bizarre, the most important, the petals flaked with scarlet and maroon on a white ground; the crimson bizarre, with crimson and rose; and the pink and purple bizarre, having purple and pink, also on a white ground. The flaked Carnations are also in three classes: The purple flake, each white petal being flaked with purple; the scarlet flake, with markings of this colour; and the rose flake, similarly marked. When exhibited a flower of any one of the foregoing classes loses in value on the exhibition stage when a petal is wholly white or coloured, and in the case of the bizarre when one colour only is present on the white ground. No two petals on one flower are altogether alike; this diversity of marking is one of the charms of the Carnation. The edged Picotees represent a winsome division, as there is something so soft, tender, and fair about them that they might be regarded as the feminine of the more masculine Carnation. The edged Picotees are grouped into four classes, viz., the red edged, the purple edged, the rose edged, and the scarlet edged, and these are further divided into heavy edges, medium edges, and light edges. The self-coloured flowers are a large and brilliant class, ranging from white to almost black. The fancies contain everything that is outside the class flowers, excepting those which are self-coloured. They may be of white or creamy grounds, or of any colour or colours on a coloured ground, but must lay claim to form, substance, and colour. "Run" flowers may be either self-coloured or go into the fancy division. They are blooms on which the white ground colour is partly or wholly suffused with some other tint. The yellow grounds, now so popular, were described, and also the new race of yellow Picotees derived from them of late years. A great deal of interest was shown in the coloured illustration of the yellow Picotee which appears in Thomas Hogg's "Treatise on the Carnation" (1824), and it was handed round for inspection. The tree or winter-flowering varieties were described, and also the spring and summer-flowering Malmaisons, now so popular, and which has received accessions of so many new varieties during recent years raised by Mr. M. K. Smith. The annual Marguerite type was also passed in review.

In dealing with the culture of the Carnation the lecturer spoke in high terms of it as a town flower, thriving under conditions amid which other plants failed; it does not mind smoke, as has been abundantly proved. The harder cultivation of the flower was warmly advocated, the bed prepared according to the directions given, and autumn planting of the same advocated as plants placed in the open air in autumn were stronger and gave better results than those wintered in frames and planted out in the spring. The necessary cultural after-planting to the time of blooming was mentioned, and also the best means of propagation, remarking that it would be well if many gardeners would grow a few Carnations in pots for blooming under glass and so secure some specially fine blooms. The method of pot culture was given and many valuable hints thrown out. The special culture necessary in the case of winter-flowering varieties, and also of the Malmaison, was given in detail in reference to the latter, early layering was recommended that the plants may become sufficiently advanced by September to be planted in larger pots.

The raising of seedlings was also touched on and directions given, and certain pests, such as weevils, rabbits, grubs, green fly, &c., mentioned; also such diseases as gout and the spot, and remedies suggested. A reference to Carnation shows brought the lecture to a close. Many questions were asked, and on the motion of Mr. W. Messenger, of Wolvestone, a hearty vote of thanks was passed to the lecturer and also to the chairman.

# THE GARDEN

No. 1677.—Vol. LXV.]

[JANUARY 9, 1904.

## THE NATIONAL POTATO SOCIETY.

**T**HE national importance of the Potato as an article of food at once places a society formed for its improvement beyond such criticisms that might perhaps legitimately be urged against it were the special product which has called it into existence of lesser value, and for this reason we welcome the formation of a society whose objects are the improvement of the Potato, and the dissemination among growers of information concerning the best varieties and other points of importance. That the proposal to form this society was viewed with general favour by growers and others interested is evidenced by the attitude of the large gathering that assembled last week to hear the initiative proposals set forth. The chief of these are to establish trial stations in various parts of the country, where varieties of Potatoes may be grown and compared and their true value thus ascertained; to form a proper system of classification for the purposes of exhibition; to encourage shows because of their great educational value.

So much conflicting evidence is circulated with regard to the merits of varieties of Potatoes that the inexperienced grower is in a quandary, and the only method by which he can escape is to grow them, and thus profit by actual experience. But experience is a hard master, and it is to save disappointments and failures, and the loss of time these entail, that the Potato Society has been formed. The great value of the Potato to all classes of the community makes the huge losses that are caused by disease all the more deplorable, and the cry to-day is for a Potato which, while being of good quality, shall have such constitutional properties as to make it practically disease proof. Here again this society proposes to give assistance. At the suggested trial stations in different parts of the country, special note will be taken of those that resist disease the best, as well as of other properties, such as good quality, yield, &c. The need for a proper system of classification is painfully evident to those who visit horticultural shows; as Mr. W. P. Wright pointed out at the recent meeting, it is not unusual to see the same variety shown in a class for round and also in a class for kidney Potatoes. Whether these experimental stations, which it is proposed to establish, will be best carried on in connexion with the various County Councils

and under the supervision of their instructors, or whether, as was suggested, they shall be undertaken by the growers themselves, and periodically visited by inspectors sent from headquarters, may well be left in the hands of the committee. So that the trials may be absolutely independent it was resolved that members of the trade be not elected upon the committee. It was decided, however, to appoint a sub-committee of members of the trade to deal with purely trade questions.

We are glad that the national aspect of the question has not been lost sight of, for the Potato is much more important to the cottager than to the well-to-do householder. Bearing this in mind, it was agreed at the meeting held last week to have a minimum subscription of 2s. 6d., so as to encourage cottagers and allotment holders to become members, and so participate in the advantages that such a society may reasonably hope to bestow. The other side of this question is also worth referring to, cottagers and other small growers might in their turn be able to give most valuable information to the society concerning the behaviour of certain varieties under certain conditions. Altogether, we think the National Potato Society begins life under conditions that augur well for a useful and successful future. It cannot fail to enlist the sympathy of all who recognise the national importance and value of the Potato. Mr. W. P. Wright, who may be said to be the originator of the scheme, and may reasonably be supposed to know most about it, has been elected secretary of the society.

## RIVIERA NOTES.

**TWENTY** years ago or more *Uhdea bipinnatifida* was recommended as a fine foliage plant for the sub-tropical garden, which was then just in vogue. Its large and deeply lacinated leaves were rough in texture and perhaps a trifle coarse, so it never became popular. The plant, however, is of real beauty when fully developed, and I, for one, had no idea of its value and importance until I saw it in a friend's garden at Bordighera the other day. There I saw what at a distance might have been an immense *Dahlia imperialis* in full flower, and as the last days of December are too late for that stately plant to be still in flower I went close up to where it grew, rather under the shade and shelter of a big Palm, and by the leaf I was able to identify my old friend. But what a marvellous development of that rather coarse plant! It is the flower rather than the leaf that is the true beauty of the plant, and the

big branching sprays of its white Daisy flowers with white centres are the finest thing I have yet seen in a December garden. It is well worth a trial in England under glass, where there is plenty of head room, for nothing could be finer for bold decorations during the months of December, January, and February—the very time when a fine bold plant is needed to make a contrast to *Camellia* and other winter-flowering shrubs. Its hardiness is just that of the *Heliotrope*, but it needs little heat when in flower, judging by its behaviour on the Riviera, and I fancy it will be much more amenable to cultivation in England than its better known forerunner the *Tree Dahlia imperialis*.

**SALVIAS** live so badly when cut and in a warm room that it is rather a surprise to find *Salvia Bethelli* or *involucrata* will really last for days in water. Its pretty cherry-red bracts and pink flowers are a relief to many forced flowers, and its leaves are so handsome that it is quite as indispensable as *Eupatorium weinmanniana* or any other well-known decorative shrub that needs little attention beyond general good culture. Small plants, however, are not to be recommended.

**RED CLIMBING ROSES** are so scarce out of doors in January that Dr. Rouges and the newer *Noella Nabonnand* are much to be recommended. They open their buds so well in a low temperature, and respond so well to severe autumn pruning in this climate, that they deserve a place in every garden. Another good winter-blooming Rose is *Kaiserin Augusta Victoria*, whose blooms open so well, while the new and lovely *Souvenir de Pierre Notting* proves quite useless; its buds neither open nor colour properly unless under glass even in this climate. It is most difficult to prophesy the behaviour of any new Rose when grown for winter flower, and one greatly regrets that so beautiful a Rose will not give good winter flowers. On the other hand, that tender and lovely yellow Rose *George Schwartz* opens admirably, and in a few years must, I think, be a great favourite here.

**SAVING SHRUB SEEDS.**—How few gardeners take the trouble to save seeds of any shrub, and yet how many possibilities there are in a few seeds I realised the other day, when two seedling *Chimonanthus* from *C. grandiflorus* produced a few flowers for the first time. Neither is quite the same as the parent, and one is both far brighter in colour and larger in size than the finest form I have ever seen, while retaining all the fragrance of the type. If only it proves as free flowering, it will be quite an acquisition, and will tempt one to save seed for another experiment.

**IRIS TINGITANA** opened its first flower to the New Year. In this climate it is simply a question of water and manure if flowers are desired. It must have a good dry rest, but if rain does not fall in September it will not start until moisture reaches it, so that one can easily have a succession of blooming plants.

Iris Vartani is another delightful Iris, but of very small stature. Its sky blue falls and slender standards are prettier and earlier here than *I. reticulata*, which it closely resembles, except in colouring. How welcome these fresh spring flowers are even here, where autumn and spring join hands and dance in the bright sunshine!

Vice. E. H. WOODALL.

## THE EDITORS TABLE.

### WHITE SEEDLING CHRYSANTHEMUM FROM AUSTRALIA.

Mr. W. H. Cooke, Kingston Hall Gardens, Derby, sends blooms of a white seedling Chrysanthemum he has received from Australia. They are of good form, fairly large, pure white, and evidently last a long time. Mr. Cooke says that all who have seen this consider it to be a first-class decorative variety, and we can readily believe it. The plants had not been disbudded, yet the flowers were some 4 inches across. This variety is a Japanese incurve. In the words of an expert who saw it the other day, "it is a flower that should certainly not be lost sight of."

### CYPRIPEDIUM INSIGNE.

Mr. Mark Webster, Kelsey Park, Beckenham, sends flowers of this favourite Orchid with the following note. The flowers are a very fine form of *C. insigne* (synthetense): "For a number of years this deservedly popular winter-flowering plant has been grown with more than ordinary success at Homewood, the residence of W. M. Bullivant, Esq. Calling on Mr. Thomas Crosswell (the gardener) the other day, I was shown six plants in 9-inch pots filling one side of a house; the pots were on bricks, and were completely hidden by the foliage. Each specimen measured 3 feet through, and looked as if cast in a mould. The flowers were not supported, but hung round in a circumference of 12 feet. The plant I counted carried fifty-five single and three twin blooms. This season the twins are not so numerous as usual, eighteen having been carried on one plant at one time. These plants have not been potted for eight or nine years. Weak farmyard drainage, Clay's Fertiliser, soot-water, and guano are occasionally given. The roots grow over the rims of the pots in a perfect mat. Plants carrying nine large blooms in 4½-inch pots are grown for indoors and table decoration."

### BEAUTIFUL FORMS OF PRIMULA OBOCONICA.

Mr. Gumbleton sends from Belgrove, Queens-town, Ireland, fine forms of this *Primula* "raised from Erfurt seed received from Messrs. Haage and Schmidt. I think them good." The flowers are large and charmingly varied in colour, from almost white to warm rose, a very beautiful series of shades.

## NOTES OF THE WEEK.

### FORTHCOMING EVENTS.

January 16.—Société Française d'Horticulture de Londres Annual Dinner.

January 21.—Gardeners' Royal Benevolent Institution Annual General Meeting at the Covent Garden Hotel; Annual Supper, Covent Garden Hotel, Mr. Leonard Sutton in the chair.

January 26.—Royal Horticultural Society's Drill Hall Meeting.

### The history of the blue Primroses.

Some twenty-five years ago Mr. G. F. Wilson raised Scott Wilson, a Primrose much talked of and admired as a new break and forerunner of a new plum-coloured strain. About two years afterwards he kindly gave me a plant of it, and we both tried to raise real blue ones. Mr. Wilson went on selecting carefully and sowing, but, as far as I have heard or observed on my visits to Heatherbank, he did not try any other proceedings. I had obtained

from Ware's plants of the "Old English blue Polyanthus" a variety with flowers of a pale sky blue with a tinge of grey, and thought that by crossing this with Scott Wilson, not only blue Primroses, but also blue Polyanthuses might result. I at once tried the cross. I had remarkable success, for I obtained about 50 per cent. bright blue shades, and also a few Polyanthuses. My strain has improved year by year, and there are even new breaks to come. As to reversion I may state that in my experience offsprings of hybrids or crosses have a certain tendency to revert to the old forms, though this can be prevented to a large degree by constant selection of seed. Another fact is the change of colourings. A plant of a blue strain may produce crimson, violet, or plum colours, whilst the colour becomes much more of a blue shade in spring, the colouring being the effect of a changing temperature, thaw, and sunshine.—MAX LEICHTLIN, *Baden-Baden*.

**Dicentra chrysantha** (page 9).—My experience with this plant is that it is quite hardy, but short-lived. With me it has never lasted more than six or eight years. I have never been able to increase it by seeds, cuttings, or layers. I have now lost it, and should be glad to know where it can be got.—H. N. E., *Bitton*.

### THE LAVENDER OF LIFE.

The world goes all too fast, my love;  
I am tired of the restless race,  
And my heart has gone back to the Roses  
In a quiet garden place—  
To the moat and the mossy sundial,  
And the Yews, where the shadows wheel,  
To the love at the lattice window  
And the song at the spinning-wheel.

The world goes all too fast, my love,  
With its dance and revel and wine;  
And my heart has gone back to the Holly-walk  
And an Oak-framed love of mine—  
Gone back, gone back for a hundred years,  
From a world of greed and strife,  
To the harp and the brodered tapestry  
And the lavender of life.

W. H. OGILVIE, in *Country Life*.

**Jacobinia chrysocephala**.—Introduced from Mexico and put into commerce over thirty years ago, this delightful winter-flowering plant after a time almost dropped out of cultivation; but within the last three or four years there has been a great revival in the matter, and it is now generally met with. This is as it should be, for the plant in question is of easy propagation and culture, and it lasts a long time in bloom, added to which the rich golden orange hue of the blossoms is remarkably effective during the half-light too often experienced throughout its period of flowering. The best coloured flowers are those developed in a clear atmosphere; and those shown on Tuesday last by Messrs. Veitch, which were grown at their Feltham nursery, were particularly well developed. This plant was first distributed under the generic name of *Cyrtanthera*, then it became a *Justicia*; but now it is settled to be a *Jacobinia*. In the same genus are now included two plants, at one time even more popular than they are now, viz., *J. ghiesbreghtiana*, known in olden days as *Sericographis ghiesbreghtiana*, which produces a quantity of scarlet tubular-shaped flowers at this season of the year, and *J. pauciflora*, which will be comparatively unknown, but as *Libonia floribunda* is generally grown and justly valued for its winter blooming qualities.

**The National Potato Society**.—No longer is this society a suggestion—it is in existence, a living reality. True, its condition is far from being a finished one; indeed, it is yet something of a framework which has to be clothed with solid flesh, but the formation and creation of even a Potato society cannot be done in a day. It has a temporary and excellent chairman in the person of Mr. A. D. Hall, the chief of the Berkhamstead Experimental Farm, with Mr. G. Gordon for vice-chairman, and Mr. W. P. Wright as secretary. A large committee has also been formed, including many of those who are engaged in the work of horticultural instruction in the counties. Subscriptions are of a moderate nature, as the minimum is as low as 2s. 6d. With such a basis there should be no difficulty in collecting, in many hundreds, members from out of the Potato growers, large and

small. What will constitute the special work of the new society has yet to be largely determined. It is for the committee elected for the present year only to determine that and to put things into shape. When it is remembered that we have no garden product, and but one other field product which has for us such importance as the Potato, there should be no difficulty in finding not only a wide field for operations, but also means for their conduct, so that a very important impression be made on Britain's Potato crops and supply, and a great food product be enormously increased. At the present moment our home produce is a very limited one, and we are greatly dependent now on foreign supplies. It is folly to decry these useful importations; they represent a valuable food supply. Largely the present deficiency is due to a most unfortunate season, one that has proved to be singularly adverse to Potatoes, and which we may well hope we shall not have repeated. It is to this shortness of crops of the past year that we owe the efforts which it is feared may have been too successful to boom one or two new varieties of Potatoes in a way that has surpassed all previous experience. These varieties have been described as marvels, and prices paid for them astounding. This sort of eulogy has doubtless trapped many rather credulous persons into purchasing them at costs that never can be remunerative. One of the aims of the new society doubtless will be to establish trial or testing plots in diverse parts of the kingdom, where new and good old varieties would be grown side by side for comparison in so many diverse soils and positions, and thus secure for the public guidance judgments as to any variety's merits that would be reliable and the reverse of misleading. It is not enough that trials of this nature should be for such object only. It would be well to ascertain also what varieties do best in certain soils and situations, how far particular soils affected starch production and flavour, how far also soil or position affected disease affinity or resistance; and especially could admirable tests be obtained as to the effects of change of seed tubers from one description of soil to another as compared with similar varieties unchanged. Results could also be obtained as to the effects of diverse methods of wintering seed tubers on crop production. Exhibitions of Potatoes would, of course, form a feature of the society's operations, as also some sort of classification of varieties. All this, of course, would necessitate considerable outlay, and it is hoped that some county councils will be induced to co-operate with the society in providing trial plots and labour through their able gardening instructors. The Board of Agriculture, the Royal Agricultural and the Royal Horticultural Societies it is hoped will also render valuable assistance.—A. D.

**Aberdean Chrysanthemum Society**.—The annual exhibition will take place in the music hall, November 18 and 19 next.—M. H. SINCLAIR, *Secretary and Treasurer*.

**North of Scotland Root, Vegetable, and Fruit Association**.—The annual meeting of this association was held at Inverary, on the 26th ult., and was presided over by Councillor Low. The secretary's statement showed the satisfactory balance of £32 4s. 3d. to the credit of the association. After some discussion, it was agreed to have a two days show on the first Friday and Saturday of November, 1904. The schedule of classes was revised, and several additions made to an already valuable and satisfactory series of prizes.

**"My Garden Diary"**.—This familiar booklet, issued by Messrs. Sutton and Sons, is a valuable garden companion, tastefully produced. It is full of useful gardening reminders for each month of the year, and there are spaces for memoranda. At the end there are "Notes on Bulbs," "Notes on Lilies," and "Secrets of Success with Flower Seeds," all of which are filled with information of value to everyone who gardens. The lists of "Bedding Annuals," arranged as tall, medium, and dwarf; "Climbing Annuals," "Everlasting Flowers," and "Edging Plants from Seed" will also be found most useful. Some remarks upon how to destroy certain garden pests conclude "My Garden Diary."

**Addition to the Glasgow public parks.**—At the last meeting of the Glasgow Town Council a recommendation by the parks' committee that the lands of Ibroxhill, adjoining the Bellahouston Park, he purchased was considered, along with a proposal that a portion of Bellahouston Park should be fenced. After some discussion the recommendations of the committee were agreed to by a large majority. Ibroxhill will be a valuable acquisition and will add much to the amenity of Bellahouston Park, while the portion of the latter it is proposed to feu can be disposed of in this way without seriously affecting the value of the grounds. The cost of the Ibroxhill lands will be almost defrayed by the sale of these feus.

**Trials at Wisley.**—An explanation as to the difference between the mention of trials at Wisley and the facts in relation as stated, is that the announcement in the Journal was printed some time prior to the issue of the number, and at that time it was fully believed that the trials would take place. Since then it has been found that owing to so much of the field ground being in so foul a condition it will not be possible to get it into a state fit for trials so soon as next spring. There can be no doubt but that great as is the gift of the garden, the Royal Horticultural Society finds it to be a horse that has to be looked hard in the mouth, and the more it is examined the greater the need for labour and expenditure. It is much to be deplored that the customary trials should fall through for a year. It may well be thought that at least a couple of acres could have been thoroughly cleared and got ready for trials; but doing so seems to have been beyond the capacity of even the Royal Horticultural Society.—A. D.

**Broughty Ferry Horticultural Association.**—The course of lectures arranged by the Broughty Ferry Horticultural Society, in combination with the County Technical Education Committee, continues to be much appreciated by those interested, and there was a good attendance at the eighth lecture of the course, which was held in the Grove Academy on the 16th ult. Mr. W. G. Anderson occupied the chair. The lecturer for the evening was Mr. A. D. Richardson, landscape gardener and consulting forester, Edinburgh, and formerly at the Royal Botanic Gardens there. He took for his subject that of "Continental Forestry," one upon which Mr. Richardson is well qualified to speak from his own experience and observation. Mr. Richardson dealt fully with it, pointing out the systems adopted and their advantages and shortcomings in a lucid manner. A capital series of lime-light illustrations added much to the interest of one of the best lectures of the course. A good discussion followed, and the lecturer was heartily thanked for his services.—S.

**Hybrid Gesneras.**—During the last few years a great improvement has been obtained by hybridisers of these plants. The colours are more numerous and distinct, and the plant has bold, pyramidal spikes of bloom often reaching 18 inches in length. The foliage alone is very handsome, being beautifully marbled in various shades. The value of these plants for indoor decoration alone should certainly give them a wider popularity, for scarcely any flowering plant stands longer under such conditions. The flowering season can be extended over a long period, when a good number of tubers are in hand, by potting up successive batches from the middle of January to April, the latter potting lasting well into November. The compost for tubers should be composed of equal portions of fibrous loam, lumpy peat, and coarse leaf-soil, with sufficient sand added to make the whole porous. The tubers start more satisfactorily by being dibbled thickly in boxes of leaf-soil and sand, placing them in a moist and warm temperature not less than 60°. When an inch or so of growth is made they should be carefully potted up in the above compost, placing five plants in a 6-inch pot. Be sure and warm the soil nicely when potting takes place to avoid chills, return the pots to the same temperature, and take care to shade them from bright sun. They will not need much water till fairly established, when copious supplies must be given. An occasional application of farmyard

manure water, diluted, is beneficial from this stage till the flower-spikes are fully developed. When the flowers begin to open keep the atmosphere drier or remove the plants to the conservatory. When ordering seed procure it from the best possible source, and so avoid disappointment when the flowering time arrives. In January or early February the seed should be sown in pans of rich light sandy soil, barely covering the seed with the fine particles; place the pans in a moist, warm temperature. Sheets of glass or paper should be placed over the pans to prevent evaporation, for nothing is more harmful to seedlings of any kind than variable conditions of the soil. When the seedlings are large enough to handle, transfer them carefully with a pointed stick into pans filled with similar compost. Repeat this operation as the young plants require it, for it will be found they will vary greatly in size. After each operation always bear in mind to fill up with soil where the young plants were taken from. Place them in the same quarters, carefully watering and shading. As they advance in growth treat them the same as advised for old tubers, but use smaller pots; 3-inch will generally be found large enough. Grow them rapidly on to form full-sized tubers by autumn, when they must be gradually ripened off and stored away in the pots in a temperature not lower than 45° nor above 50° for their rest. Should a scarce variety appear, leaves taken off with a bud at the base would increase the stock quickly, inserting them in sand under hand-lights plunged in bottom-heat.—G. ELLWOOD, *Swanmore Gardens*.

**Calanthes at Woolton Wood.**—The Calanthes, so well grown at this establishment, are now shown to advantage in a large span-roofed structure; the sorts are *Calanthe Veitchii*, *vestita oculata*, and *v. rubra*. There are nearly 100 pots with upwards of 400 spikes, many over 4 feet in length, and in addition there are a few own-raised seedlings, which have a distinct colouring in the lip. The pots are arranged thinly with Ferns and other greenery as a base, the whole forming a charming display at this dull season. Another advantage is the length of season, which in this case covers a period of from October to early in February, and, in addition to being so beautiful as decorative plants, they can be utilised with charming effect for dinner table or general house decoration. *Calanthe Williamsii* promises to continue the succession by showing bold spikes that will follow later on. Mr. R. Todd is to be congratulated upon his successful culture of this useful winter-flowering plant. In addition to the Calanthes a large number of *Cypripediums* are now in bloom, including many raised in these gardens, showing considerable variety in colour, size, and form.

**Then and now.**—The various notes from Covent Garden Market which have of late appeared in THE GARDEN are of great interest to me, for some thirty years or more ago I was employed in a (at that time) prominent market establishment, and the subjects then grown were in numerous instances very different from those of to-day. The system of retarding has in many cases completely revolutionised some classes of plants—for instance, the Lily of the Valley, which we were for several seasons the earliest to take into the market. The system then adopted was to get good, well-ripened Berlin crowns, pot them eighteen in a 4½-inch pot, just leaving the points out of the soil, and plunge in a close propagating case in the stove with a bottom-heat of 80° to 85° and a moisture-laden top-heat of 75°. With all this we were considered fortunate to get a few in flower by the first or second week in December, but the main object was to get a good crop by Christmas, when high prices were realised. At that time 1s. a spike was the ordinary price about Christmas—that is, first hand. There were in those days no species of *Lilium* at this season, for all those now in the market are the product of retarded bulbs, and it was some ten years after that before we first got *Lilium Harrisii* from Bermuda, by which means we were enabled to get the long Trumpet Lilies early in the new year. The Arum Lilies (*Richardia*) then as now were very popular, and of other flowers *Camellias* were grown far more than they are at the present day. Very few zonal *Pelargoniums* were to be met

with at this season, the first to attain a considerable amount of popularity for winter blooming being the semi-double Wonderful, sent out about 1875. *Chrysanthemums* were few in number compared with to-day, while *Marguerites* and *Freesias* were almost unknown. *Epiphyllums*, whose flowers readily lent themselves for use in the formal pin-cushion-like bouquets then in vogue, were taken into the market in considerable numbers, and much the same may be said of the climbing *Tropaeolums*. One variety—Mrs. Treadwell—was very popular for the supply of cut flowers in midwinter, a position it held till ousted by the zonal *Pelargoniums*. Of foliage plants, the principal Ferns of those days were *Adiantum cuneatum*, *A. decorum*, *Pteris tremula*, and *P. serrulata*. *Pteris cretica* was at that time gaining in popularity, but the major variety was quite unknown to the market grower. Palms were at that time very little met with, far and away the most popular being *Latania borbonica*, for the now universally-grown *Kentias* were valued at guineas. Next to *Latania* perhaps came *Areca lutescens*, *Seaforthia elegans*, and *Corypha australis*. A very pretty plant, and a one-time universal favourite, is *Cyperus alternifolius*, but this is now very little grown to what it once was. In the days when small Palms were so scarce, *Curculigo recurvata* was often grown as a substitute; now, however, it is almost forgotten.—T.

## ON THE LAGO MAGGIORE.

THE Italian Lakes (Como, Ceresio, Maggiore), these three together, form a specially favoured region known scientifically as the insubric zone. Sheltered as it is from the northern blasts by the great wall of the Simplon and Gotthard Alps, and protected by their southern-facing slopes, these conditions of shelter and warm exposure are of themselves extremely favourable. But the main source of the rich flora and special character of the region is the enormous volume of heat that is given off by the deep waters of the lakes, and the almost entire absence of cloudy days. The lakes are of great depth, and it will be seen that from this immense mass of water an abundant supply of warmth is given off, the water of the lower depths constantly rising to cool on the surface and bringing with it an appreciable degree of warmth. To this is added soil of a special chemical composition, almost entirely wanting in lime, and we have the explanation of the phenomenon that produces a flowery oasis at the foot of the Alps, while further south, as at Milan, the climate is much colder and the vegetation of a more northerly character.

I have travelled about these lakes at all seasons, and from one year's end to another have never seen them without flowers. Rising one above another are the most wonderful gardens, and a luxuriant exotic vegetation is to be seen in all directions. The great Borromeo family were the founders of the gardens which were here established several centuries ago; they were the first planters of rare and beautiful trees and shrubs on the shores of the Lago Maggiore. The Borromeo Islands, which, with the adjacent shores, were the sites of the gardens of the lordly Milanese families, have furnished examples of a luxuriant wealth of gardening that all the world has desired to adopt and reproduce.

But to bring about all that the region has now to show there was need of the labours of specially intelligent and enterprising horticulturists, who should introduce and distribute suitable exotic plants. I believe that the superb vegetation that we now see on the shores of these enchanting lakes is largely due to the work of two generations of the Brothers Rovelli. I have just lately visited this firm's excellent and interesting horticultural estab-

lishment, now in the hands of the young *Docteur es Sciences*, Renato Rovelli, grandson of the original founder. A brief sketch of it may, I hope, interest readers of THE GARDEN.

The garden stands out upon a spur of land that juts out into the waters of the Lago Maggiore, forming a cape, the greater part of which belongs to it. The highest point is from 25 mètres to 30 mètres (nearly 100 feet) above the lower portion of the garden. It has become a delightful spot, shaded by magnificent Mexican and other Pines, and commanding a superb view of both shores of the lake.

The vegetation is quite Mediterranean, and to see the long-leaved, domed tops of the Eucalyptus swaying above groups of *Jubæa spectabilis* and *Acacia dealbata* one might be at Cannes or Mentone. The Japan Medlars (*Eriobotrya*) are self-sown, and young plants of it are to be seen on all sides. *Ficus repens* climbs about the walls, and the air is fragrant with the scent of *Olea fragrans*. Much taste has been shown in the laying out of the pleasure ground. Here are to be seen the strange but pleasing outlines of *Abies lasiocarpa* 30 feet high, *Pinus lambertiana* 45 feet, *Pinus winchesteriana*, *fremontiana*, *Koraiensis*, *daveana*, and *longifolia* from 20 feet to 50 feet in height. The curious dark-complexioned *Pinus insignis* finds itself a near neighbour of the *P. Cembra* of the high Alps. The strangely-sinuous *P. russeliana* spreads out its tortuous, serpent-like branches on all sides, in strong contrast to the stiff 60 feet high spire of *P. palustris*. *Pinus patula* spreads its great arms widely abroad near an *Abies Fortunei* 45 feet high, while a *Thuja gigantea* of 65 feet shows off by contrast the strange shape of a *Cupressus torulosa*, also a giant. *Sciadopitys*, *Torreya*s, various *Podocarpus*, American and Japanese Oaks—all are interesting and show great vigour. *Laurus glandulosa* and *L. camphorata* are 60 feet high. *Magnolias* are of great size, and *Pueraria* throws its great unctuous branches about on all sides. All these form delightful groupings of highly pictorial effect.

There are also several acres whose planting seems to consecrate them not only to botanical science, but to poetry and other fine arts, and it is with indescribable pleasure that I enjoy and admire them at each fresh visit. It would seem that the shades of a Ruskin or a Goethe must haunt the hidden recesses of this beautiful pleasure ground.

Rare species are in abundance. I will only name a few of their number: *Quercus Mirbeckii*, *Banisteri* and *dealbata*, *Juniperus squamata*, *Ilex depressa*, *Castanea japonica*, *Abies clambasiliana*, *Fitzroya patagonica*, *Illycium religiosum*, *Tristania nerifolia*, *Colletia biconensis*, a collection of *Grevillea*, and a number of *Ilex*.

The glaucous heads of *Acacia dealbata* rise above *Benthamias*; the delicate and beautiful *Pinus canariensis* and many kinds of rare Bamboos border the paths through the groves. The undergrowths are of bushes, such as *Lagerströmia indica*, *Olea fragrans*, *Thea viridis* and *sinensis*, *Camellia*, *Weigela*s 12 feet to 15 feet high, *Hypericum patulum* attaining a height of 9 feet to 10 feet, *Arbutus Andrachne* 35 feet, &c. In place of turf there is *Ophiopogon japonicus*, and in places the ground is covered with the Winter *Heliotrope* (*Nardosmia fragrans*), or by the Caucasian Borage (*Borago orientalis*).

Special grounds are reserved for a more prosaic class of cultivation, for stocks of *Camellia*, *Azalea*, *Chamærops*, *Ficus*, *Laurus*, *conifers*, &c.

The speciality of the garden as a nursery is the cultivation of the famous *Pseudo-larix*

*Kæmpferi*, the most capricious of known conifers, but which does well here at Pallanza.

M. Enrico Rovelli, the uncle of the actual proprietor of the garden, has established himself on the other side of Pallanza, where he has acquired a magnificent property. Here he grows specialties, such as Carnations, *Musa*, also flowers in general, conifers, &c. He is a skilful landscape gardener, and has planted delightful pleasure grounds.

The fine avenue of *Magnolia grandiflora* which borders the lake all along the length of the quay is the outcome of the generosity of the Rovelli family. From one year's end to another the blossoms scent the air, while their lustrous evergreen heads show out against the clear blue sky, and their dark trunks against the azure of the pure lake waters.

Happy land, beloved of the sun! land of flowers and sweetest perfumes. Would that one might dwell therein for ever!

*Floraire, Geneva.* HENRY CORREVON.

## THE FLOWER GARDEN.

### LILIUM JAPONICUM.

FEW Lilies have given rise to so many differences of opinion as *Lilium japonicum* of Thunberg, but it is now I see, according to the "Kew Hand List," identified as the Lily so long grown in gardens as *Lilium Krameri*. On this point I am not in a position to say a word, being without the ample reference at the disposal of the Kew authorities, but of the two varieties included under the head of *L. japonicum*, I quite fail to see their relationship to the Lily in question, except as far as they are all members of the same genus.

The first, *L. japonicum Alexandræ*, attracted considerable attention ten years ago, when it was awarded a first-class certificate by the Royal Horticultural Society, being shown by one of two exhibitors as *L. Alexandræ*, and by the other as *L. Ukeyuri*. It was at that time generally believed to be of hybrid origin. The probable parents suggested were *L. auratum* and *L. longiflorum*, and certainly the general appearance of this Lily would bear out such a theory, for neither in bulb, foliage, or flower does it bear the least resemblance to *L. Krameri*. I am aware that at the time it was first exhibited Mr. Baker ignored the supposed hybrid origin, but at all events it may have been a natural if not an artificial hybrid.

The second variety to mention is *L. japonicum Colchesteri*, of which *L. odorum* is one of the synonyms. This has really nothing whatever to do with *L. Krameri*, its nearest relative being *L. Brownii*, with which it was at one time often confounded, but from which it differs in the thinner leaves, shorter flowers, with the interior of a yellowish tinge, rather than the ivory white of *L. Brownii*. This last-named species is assigned specific rank, and its native country given as China and Japan, but concerning this there seems some doubt, as the origin of *L. Brownii* of gardens and as grown by the Dutch is wrapped in obscurity, and among bulbs imported either from China or Japan I have never flowered any that would be confounded with it.

The comparatively new *L. rubellum* is in the "Kew Hand List" classed as a true species. Why, it is impossible even to guess, taking as one's standpoint of species and varieties *L. japonicum* (*Kramerii*), with the so-called varieties *Alexandræ* and *Colchesteri*, for *rubellum* is in every respect closely allied to *L. Kramerii*, there being the same bulb, style of growth, and almost of flower, while both have a knack of disappearing after the first season. Great things were at first expected of *L. rubellum*, but it has proved little, if at all, more amenable to cultivation than *L. Kramerii*.

To try and clear up some of the confusion I have referred to Mr. Baker's paper on "New Lilies" read at the Chiswick conference in 1901, and find *L. japonicum Alexandræ* thus referred to: "Bulb

like that of *L. longiflorum*. . . . Differs from the type by its broader leaves and longer style, and, I would add, in almost every other respect.

The second variety of the "Kew Hand List," *Colchesteri*, Mr. Baker calls *L. Brownii odorum*, which, if *Brownii* be the species, is certainly its proper place, but this opens up another element of doubt, as *L. odorum* is supposed to have been introduced many years before the advent of *L. Brownii*, hence if priority of nomenclature counts for anything the species should be *L. odorum*, and the other a variety thereof.

In taking exception to *Alexandræ* and *Colchesteri* being regarded as varieties of *L. Kramerii*, I may perhaps be allowed to call attention to the fact that everyone now regards *L. sulphureum* as a grand Lily and a very distinct species, yet at first it was, to the surprise of all, named *L. wallichianum superbum*. It was only universal criticism that induced our botanical friends to give it the specific rank that it should have occupied from the first.

H. P.

### HARDY CRINUMS.

THE Crinums are an African genus of stately bulbous plants numbering about 100, but of these eight only can be grown in the open, and then the best of them need winter protection. They are robust plants of a gross-feeding type, ornamental in all the stages of their growth, and their flowers borne on tall scapes in the form of loose umbels are at once graceful and refined, and their colour tints vary from white to deep pink. With the exception of the old *C. capense* their use in gardens has been entirely overlooked, notwithstanding their acknowledged beauty, especially when grown in large clumps, and the fact that but little care is needed in their cultivation, save during winter, when with such plants as *C. Moorei*, *C. Schimperii*, and *C. yemense*, a covering of light, dry leaves is necessary to ward off excessive frosts.

The soil for Crinums should be light, deeply tilled, and well drained, and in most cases it is a wise plan to establish the bulbs in pots before planting in their permanent quarters, for it is necessary to bury the necks of the bulbs up to the leaf bases in order to protect them from cold, and dormant bulbs planted deeply generally start badly owing to the coldness of the soil at the planting season. Raised beds in the front of glass houses, at the foot of a south wall, or a warm, dry border suggest themselves as likely places to suit Crinums; but soils that are poor and hungry should be avoided. On the other hand, wet and naturally cold soils should be raised above the general level and sloped towards the sun, so that moisture cannot stagnate. Spring is the best planting season, and if the bulbs are turned out of pots they will grow away and flower well the first season. If planted as dormant bulbs their first flower-spikes are, as a rule, produced too late in the year for proper development, and thus a whole season is lost. The hardest plant of the lot is

*C. capense* (known also as *C. longifolium*).—It has long, glaucous, tapering leaves 2 feet to 3 feet long; cone-shaped bulbs with shortened necks, from the sides of which the flower-scapes arise in summer, reaching a height of 2 feet to 3 feet, and bearing long-tubed, pink-tinted flowers in umbels of six to ten, shaped like an attenuated funnel, and with arching tubes of a greenish tint. They are sweetly fragrant, but are somewhat sparingly produced until the plants develop into large clumps, when twenty to thirty scapes appear at the same time. The flowers are often 6 inches long and at least 3 inches across the petals, but as they are naturally drooping and do not expand fully they never give so fine a display as the hybrid *C. Powellii*. A pure white form is widely grown. This Crinum may be grown in any plant border without protection in most parts of Britain, but it reaches its finest stature in the southern counties.

*C. Moorei* (*C. makoyanum*) is the finest species than can be well grown in the open. It is not hardy, and protection will need to be thorough if it is left out all winter, or the bulbs must be buried quite a foot deep if they are to be considered safe. For general purposes it is better to lift the bulbs in

November and store them in a frost-proof building till planting season comes round again; the bulbs keep perfectly fresh if stored in sand or fibre. It has stout bulbs 1 foot to 2 feet long; broad, arching, deep green leaves, 4 feet to 6 feet long, and tall thickened flower-scapes, which vary in height from 3 feet in the open air to 6 feet when well grown under glass, and they bear from six to twelve rosy pink flowers with long arching tubes and broad

*C. Schimperii*.—A rare species, with shortened bulbs, erect-growing leaves arranged in two ranks, and long-tubed flowers, which resemble those of *C. capense album* in general outline. It grows well without protection in any warm border. The flowers are pure white, 9 inches long, in clusters of six during August. It is a pretty plant, quite unknown to general cultivation. The flowers are delightfully fragrant, especially at sunset. It hails

All the *Crinum*s are easily raised from seeds, but four years must elapse before the specimens can flower. Offsets are freely produced by those species that do not naturally rest; the others are less free in natural increase. M.

## THE ROCK GARDEN.

### ROCK GARDEN-MAKING.

XV.—ROCK-BUILDING WITH REGARD TO THE PLANTS TO BE GROWN.

**I** WILL deal briefly with another most important subject, namely, the construction of rocks with regard to the plants that are to adorn them. It cannot be denied that, however effectively the rocks may be arranged, their beauty can easily be marred or enhanced by the subsequent position of the plants. It is for this reason that "masonry" rock gardens are always a failure. Whoever designs and arranges the rocks is the proper person to direct the planting also. More than this, even during the construction of the various rock-beds, &c., which compose the rock garden, it is absolutely necessary for the designer to have a clear idea of what kinds of plants will give the best effects for the various parts of the work. I have pointed out in a previous chapter that in rock-building much effect can naturally be produced by way of contrast. A projection adjoining a deep recess will emphasise the latter, for the same reason as a high point will be emphasised by an adjoining depression. But supposing after completion of the work the planting is entrusted to unskilled hands and without regard to artistic effect, the probability would be that the recesses and depressions alike would be filled up with plants that grow to a considerable size, and small plants would be used for high points and projections; in other words, the bold effect originally intended would be utterly ruined by a mode of planting which has decreased instead of increased the intended contrast. As a rough kind of guide (liable to exceptions) it may, therefore, be suggested that tall or vigorous-growing plants should adorn the highest and most prominent parts of the rock garden, while the

NO. 1.—THE WRONG WAY OF PLANTING ALPINE PLANTS.

N.B.—The roots are able to spread too close to the surface, and would be quickly affected by too much drought or too much moisture.

petals, which expand fully, so that the flowers measure 6 inches across. Very large bulbs bear three or four scapes at the same time, and such specimens are not difficult to obtain or to grow. Under greenhouse treatment *C. Moorei* flowers at various seasons, both when in full growth and when dormant, but in the open it flowers in August and September, when growth is at its height. It is one of the finest bulbous plants I know.

*Var. album* (syn. Schmidtii) is a lovely white flowered form, quite as vigorous and easy to grow as the type plant. Both these *Crinum*s require abundance of water when in full growth, and they appreciate the assistance of liquid or artificial manure when about to flower.

*C. Powellii*, a very hardy hybrid between *C. Moorei* and *C. longifolium* (capense), is an invaluable border plant, growing and flowering very freely, and forming huge clumps bearing dozens of flower-scapes in the course of a few seasons' vigorous growth. It resembles *C. Moorei*, but the leaves are narrower, more channelled, and ascending. The flower-scapes average 3 feet to 4 feet in length, and are thrust a foot above the ample leafage, bearing a fine umbel of rich rose flowers with long, tapering, arching tubes, and broad, funnel-shaped limbs 5 inches across. They are pleasingly fragrant, and last long in good order. Strong clumps often bear a succession of spikes, and I have gathered good flowers within a few weeks of Christmas from plants in the open. There are two seedling forms, *album*, a beautiful long-tubed, pure white variety, and a pale pink form known as *intermedia* and *rubrum*, of very soft and refined colouring. These *Crinum*s require a warm situation and a deep soil of good tilth, and they are better able to establish themselves thoroughly if planted in spring. They may require protection in abnormally severe winters, but generally they are able to survive mild winters without any covering whatever. In any case where covering is used it should be removed immediately it is not required or the woolly tunics of the bulbs will decay through want of air, and a layer of sound tissue often decays with it. One can recommend *C. Powellii* and its forms as garden plants of more than ordinary interest, bright and showy to a marked degree; the flowers are fragrant, refined, and shapely, appearing at their best towering in graceful umbels above their own lustrous leafage.

when in vigorous growth. I do not know the plant's origin, and it appears to be a hybrid.

*C. yemense*, a plant of recent introduction, is a real gain. It has globose deciduous bulbs, leaves that resemble those of *C. Powellii*, but shorter, and it bears in midsummer clusters of pure white flowers, the tubes of which are curved, and the petals broad and spreading. The plants do not appear to produce more than one scape annually, but that is always strong, and the umbel contains twelve to twenty flowers, reaching a span of 18 inches when fully developed. Its short bulbs and deciduous character render protection easy, and a layer of light dry leaves shaken over the bulbs when frost approaches will be sufficient protection. As a pot plant this *Crinum* is invaluable. It is not so bulky as some, and the grand inflorescence of beautiful flowers reminds one of the *Yuccas* in their effective display. It is considered to be a form of *C. latifolium*, a tender but very beautiful species that one often recognises in collections of rare and choice plants. One hears much of a beautiful series of hybrid *Crinum*s raised in South European nurseries that are described as very hardy and embracing some newer shades. If they are as varied in colouring as one is led to understand, and they are likely to prove as hardy as those we have already, there is room for them in the more sheltered corners of English gardens. *Crinum*s are known to intercross more readily in warmer climates than our own, and many tender species could be used by the hybridist that would be difficult to manage here as pot-grown specimens.

NO. 2.—THE RIGHT WAY OF PLANTING ALPINES.

N.B.—The roots cannot spread close to the surface, but are compelled to go down to a considerable depth, where the soil is cool and moist.

lowest and receding parts should be furnished with plants only a few inches in height, which, by forming a carpet between the higher rocks, would emphasise the bold effect; while for the boldest parts of the rock garden bold plants and even rock shrubs might be most suitable. There would be no class of plants so well adapted for the lowest parts of the work as alpine plants.

## THE REQUIREMENTS OF ALPINE PLANTS.

By alpine plants in the general sense of the word are meant dwarf mountain plants from various parts of the world. While the majority of them, perhaps, have their native home in the Alps of Southern Europe, others of equal beauty and of equally easy culture have found their way to the British Isles from the Himalayas, from China and Japan, and even from the Rocky Mountains and other portions of America.

Before considering the best ways and means of cultivating these plants in our rock gardens, we shall do well to study them in their native home, say, for choice, in the Alps of Switzerland. Who among the travellers in that charming country has not been struck by the abundance of alpine flowers and their glorious colours? Who has not admired the dense cushions of stunted foliage bedecked, as with jewels, by exquisite flowers in the greatest profusion, and often in places where growth of any kind would seem almost impossible owing to scarcity of soil and intense cold. But alpine plants differ from most other plants, and in the course of ages they have adapted themselves to the peculiar circumstances of their surroundings. In high altitudes they have to withstand a broiling sun, while their roots are down ever so far in narrow chinks and fissures, where the scanty food they find would be cool and moist. Even during the height of summer their foliage is frozen stark and stiff every night, and what little growth takes place has to be accomplished during a few hours at mid-day. The expansion and contraction of the cells of such plants during day and night must be enormous, and enough to tear the tissues of ordinary plants. But these sturdy mountain gems are specially constructed to meet all emergencies; their cells are small and their cell-walls are abnormally thick. This accounts for the toughness of the tissues. For six or eight months during the year they are covered by soft, downy snow, and when in spring the balmy southerly winds known as the "Föhn" melt and disperse the snow, the alpine flora awakes from its winter rest as if by magic. In an incredibly short space of time all is life and beauty, till in October the downy snow again provides a protecting covering for the tiny gems.

Such is the life of alpine plants at home. They enjoy an abundance of the purest possible light, and though they may be short in stature, their roots, in order to find the nourishment required, have been compelled to penetrate deeply into the narrow crevices of the rock, and it is not at all unusual to find that plants only 1 inch or 2 inches in height send their roots to a depth of several feet.

## CULTURE OF ALPINE PLANTS.

In order to apply the lessons we are taught by Nature with regard to alpine plants, I have sought to further illustrate my meaning by means of the accompanying sketches bearing on the planting of alpine plants in the rock garden. Diagram No. 1 shows the wrong way of planting. In this sketch it is assumed that the plant has been put in like an ordinary bedding plant (as is so often done) between upright stones some distance apart. Now what must be the consequence of such planting? The stones would exclude light and air, which are so essential to the well-being of the plant; but, worst of all, an alpine plant planted in the manner indicated by the sketch would spread its roots close to the surface of the soil, where—since a natural covering of snow cannot be depended upon—the slightest excess of moisture or an excess of drought would be fatal to its existence.

In sketch No. 2 I have tried to represent the right method of planting alpine plants, viz., in a deep, funnel-shaped, narrow fissure between stones let deeply into the ground. These crevices are filled with soil and small stones in such a manner as to constitute a number of miniature earthy channels, through which the roots can penetrate to a medium of richer soil at the bottom, and to such a depth that drought or excessive moisture would leave them equally unaffected. It must not be supposed that such structures of rocks prepared specially for choice alpine plants need present an unsightly or unnatural appearance externally. On the contrary,

with a little thought and skill, the useful and the ornamental may be combined in such a way that the newly-constructed rocks present a picturesque and natural appearance, and yet answer all the requirements of the choicest alpine plants. Sketch No. 3 shows how a narrow, upright fissure among rocks might be adorned by putting in, sideways, a number of plants which prefer such a position. The actual planting operation will be described in a later chapter.

Elmside, Exeter.

F. W. MEYER.

(To be continued.)

## THE LILIES.

(Continued from page 7.)

*L. CORDIFOLIUM* (Thunb), the Heart-shaped-leaved Lily.—A lovely white-flowered Lily from Japan, rarely seen in this country in good condition. It is closely allied to the giant Himalayan *L. giganteum*. Bulbs as in *L. giganteum*, but smaller, fewer scaled, the scales are

NO. 3.—ALPINE PLANTS PLANTED SIDeways INTO AN UPRIGHT FISSURE.

thickened at their bases, white, browning on exposure, perishing with the inflorescence, which it develops in the fourth and fifth year from seeds. Roots stout, deeply descending. Stems hollow, green, three-quarters of an inch in diameter, tapering, 4 feet high. Leaves: Those from the bulbs broadest and with long, fleshy foot-stalks, resembling those of cultivated Beet in general appearance, stem leaves much smaller, 3 inches to 5 inches broad, aggregated at the middle of the stem, pale green, flaccid, generally six to eight. Flowers four to six, in a short spike, white, tubular, expanding but slightly, marked with purple low down the tubes, ascending or slightly drooping, 6 inches long. Stained purple on the mid-ribs, 1 inch to 2 inches from the base externally. Very fragrant. Not common in cultivation. Flowers in August. A miniature of *L. giganteum*, growing but poorly in the open air in Britain. Inhabits deep forests of

Japan at low elevations, growing in masses of leafy deposit in shade.

**CULTURE AND USES.**—This Lily, a charming plant when well grown, requires a warm, shady situation and a root run of leaf-soil. One cannot grow it well in the plant border, but it is likely to thrive among Ferns and in semi-wild rockeries, "rooteries," and such places. Our experience with this plant leads us to advise that it can be grown in cool green-houses. It is a better pot plant than *L. giganteum*, which never seems happy thus treated, and the cool fernery appears to be its proper home.

*L. croceum* (Chaix), the Orange Lily.—A well-known cottage garden plant. It is the most easily managed of all its race. Bulbs large, 6 inches to 15 inches in circumference, often compound, flat topped, white or straw-coloured. Stems 4 feet to 5 feet high, irregularly angled, dark green, purplish below, downy when young, producing quantities of roots from their bases and three to six bulbils among them. Leaves stout, narrowly lance-shaped, numerous, deep green, arching, aggregating into a loose whorl below the inflorescence, a few inches of stem bare below it. Flowers on branched foot-stalks, ten to twenty in a pyramidal branched spike, erect growing, shaped like a very wide funnel, 5 inches across, the petals broadest near the tips, coloured orange, paler externally, dotted in the lower two-thirds, the dots raised on small petaloid processes, which gradually merge into two parallel hairy ridges on the claw. Flowers in July, common in cultivation. Native of South Europe, found under all possible conditions of soil and climate, generally one to two-flowered in a wild state. Exceptionally easy to grow.

*Var. hiemalis*.—An early flowering form, is often found in gardens as *L. croceum*, especially in the Midlands, where it appears to have superseded the type. It is apparently the same as the variety Chaixi of earlier authors. It grows 3 feet high, has slender stems and leaves, flowers narrowly funnel-shaped, six to eight on a spike, and the spotting is very light. Their foot-stalks are 2 inches long and abruptly ascending, so that the flowers are closely pressed to the stem, and, being 6 inches to 8 inches distant, do not make such an imposing pyramidal inflorescence as *L. croceum* does. It cannot be described as a better garden plant than *L. croceum*, but it is certainly neater, and the flowers appear more refined in shape and colouring. Its bulbs are generally smaller, and the flower-buds are very prominent when the spike pierces the ground. Flowers regularly six to ten days earlier than *L. croceum*. Unknown in a wild state. Common in cultivation. Flowers early in July.

**CULTURE AND USES.**—*L. croceum* and its form require no specific treatment. They belong to the rank and file of garden Lilies whose simple requirements are fully met in most gardens. They dislike considerable moisture, manure at the roots, and they grow better in the light soil of plant borders than in peat. Where old-established clumps show signs of wearing out a mulch of manure laid upon the surface in winter will help if the bulbs are not too crowded. Deep planting will ensure fine development in the flower spikes, for they root freely at the bases of the stems, and, if required for such a purpose, they may be grown well in roomy pots, but *L. croceum* is happiest in the border. It is one of the few Lilies that one may use in wild gardens with certain success, and we have seen it thriving well in cultivated shrubberies.

*L. dauricum* (Ker. Eawl.).

*L. dauricum* (Hort.), the Siberian erect-flowered Lily.—A well-known garden plant, which some consider belongs to the umbellatum group, a race of European origin; but we think they show in all stages of their growth a more definite alliance with *L. bulbiferum*. Bulbs white, like a small croceum, scales much contracted at the middle. Stems 2 feet high, very pungent when fractured, downy above, rooting freely from their bases, green or brown. Leaves linear, scattered, closely arranged, the smallest near the top and bottom, 3 inches to 5 inches long. Flowers six to eight in a perfect umbel, erect-growing, 4 inches long and wide, coloured reddish with buff shading, sparsely dotted low down internally. Odour rather unpleasant. A free-flowering Lily of easy culture, but its colouring is not so pleasing as that of *bulbiferum* or *croceum*, with which it flowers in July. Collected bulbs from a large and diversified area reveal no variation from the type. Siberia and contiguous countries, inhabiting a large territory.

**CULTURE AND USES.**—Like most of the cup-flowered Lilies, this one can be well grown in any plant border, and its uses are akin to those of the last species, *L. croceum*, but the plant is altogether smaller.

(To be continued.)

## THE FERN GARDEN.

### THE MOUNTAIN LASTREA.

*LASTREA MONTANA* (OREOPTERIS).

ONE of our native species, which is practically never seen except in its wild state or in special collections, and yet is decidedly one of the most interesting and one of the most generous in beautiful varietal forms, is the above.

It is also one of the very few Ferns with a pronounced and pleasant odour, its fronds being covered with tiny glands containing an oil with a decided Lemon-like scent, which is imparted to the hands if the fronds are gently drawn through them. By this it can be infallibly discriminated from other species, a fact which it is advisable to remember, as otherwise it bears a very strong superficial resemblance to the common male Fern. It differs, however, in its pronounced yellowish green tints, and also in having side divisions (pinnæ) of the fronds continued right to the base as roundish lobes, while the male Fern has a distinct naked stalk, the pinnæ commencing some few inches up. The Mountain Lastrea is by no means a rare Fern. It is found in immense numbers on hill slopes and in mountain ravines, hence its name; but it is by no means confined to elevated habitats, and we have found it in Epping Forest, in the Weald of Kent, and in the several Sussex forests—in the last-named, indeed, in as great abundance as on the hills of Lakeland and Scotland and Wales. In its requirements it differs from many Ferns in its preference for sandy, yellow loam, and its dislike of lime; and we find that it grows well under pot culture in a mixture of such loam with a little leaf-mould, and the use of rain water only. Drought it cannot stand nor stagnant moisture, hence good drainage must be provided. In the open it will thrive in moist situations, and stands plenty of air and light, as indeed must be implied by its natural habitats. By the sides and on the slopes of mountain streams it exists in thousands, knee high, and in clumps of many crowns together, and often attains a height of 3 feet and more close to the water's edge.

It is a curious fact that up to the middle of the last century this species was regarded as one of the most constant and non-sportive of our native Ferns. Then, however, some of our best known Fern hunters, Mr. J. M. Barnes especially, began to find good varieties, and, stimulated by this, they

and others devoted themselves so assiduously to the search, that eventually a very large number of quite distinct crested, curled, narrowed, truncate, and even plumose types were acquired. The original opinion as to constancy was thus quite upset, and it is rather a puzzle at the present day to account for it, in view of many finds made and their often conspicuous nature. We ourselves, for instance, found an enormous specimen on Dartmoor of a beautifully tasselled form (*L. m. cristata gracilis* Drnery), which needed a horse and cart for its removal and two men to lift it. A year ago we found a beautiful plumose form in Longsleddale, near Kendal; and this year within a quarter of a mile of that find Mr. Smithies found quite a number of conspicuous plants of a heavily grandiceps crested variety—so far unique—and plainly visible twenty yards away. This was in a locality where numerous ardent hunters reside, and forms another proof of the practical inexhaustibility of habitats where many thousands of acres and millions of plants are concerned. Nothing but the actual experience of such discoveries as these can bring home to the mind the subtle and envious influences which must lead to such striking and permanent alterations of normal structure as these "sports" evince. Millions of normals are all around one, and all growing apparently, and, we think, really under identical environments; the soil, aspect, and situation are identical, and yet we suddenly find a clump of a hitherto unknown type, perhaps isolated, and perhaps intimately mingled with the normal. When we lift it and put it under culture it is as stable as any specific form, and almost invariably yields like plants from its spores generation after generation.

*L. montana* differs from other Lastreas in being difficult to raise from its spores artificially, though in its habitats the youngsters often swarm in every crevice of the soil or rock. Mountain air seems necessary, since in all our attempts, although the spores germinate freely, they damp off before completing their functions. Bits of the old caudex or root-stock, however, dipped into a tumbler with a little wet silver sand and kept close soon produce bulbils which rapidly develop into pretty plants true to type. This species is also thoroughly deciduous, the fronds shrivelling and dying down entirely in the autumn. In the spring they rise again rapidly, and in so doing display a peculiarity

which enables the species to be recognised. The male Fern's fronds lift crozier fashion, the tip of the coiled-up frond falling loosely down as it unfolds. In *L. montana*, however, the tip maintains a hall-like form, the minor divisions projecting laterally and rendering its spikes like Magog's weapon, a peculiarity only shared by its near relative the honest Fern (*L. Thelypteris*). This Fern is so beautiful, and especially its crested and plumose varieties, that we strongly counsel our readers to admit it more freely among the other species in their hardy ferneries.

CHAS. T. DRUERY, F.L.S., V.M.H.

## NOTES ON HARDY PLANTS

### TROPÆOLUM SPECIOSUM.

(FLAME FLOWER.)

CLOSE to the park gates here stands the cottage shown in the illustration. A good portion of its outer surface is covered with this *Tropæolum*. The natural soil is of a moist alluvial character, and the cottage is not more than 400 yards from the river Wharfe, which here is influenced by the spring and neap tides. I merely mention this to show the kind of situation. A small plant was put in some few years ago, and it has increased very freely, its underground rhizomes sending up growths some distance from the original plant each year. When trimming the decayed growths away each autumn some of the main shoots are left. They break out again in the spring several feet up the cottage. In the gardens here not more than half a mile away we cannot get this creeper to grow at all. We have tried it in several positions. Our natural soil is a strong loamy limestone. The occupant of the cottage (the house carpenter) is naturally very proud of his success. I ought to mention that the cottage faces west, but the sun's rays are broken by some old Apple trees not far distant.

Grimston, Tadcaster.

### A FIELD OF BRITISH ORCHIDS.

It may to many seem somewhat extraordinary to write of a field of Orchids in England; but such

THE FLAME FLOWER (*TROPÆOLUM SPECIOSUM*) OVER COTTAGE PORCH.  
(From a photograph by Miss Alice Fielden.)

THE WHITE BACHELOR'S BUTTONS (*RANUNCULUS ACONITIFOLIUS*) BY A SHADY WALK.

an occurrence is not altogether uncommon in some districts. A few years ago, while botanising in the neighbourhood of Burnham Beeches, I came upon the most beautiful display of wild flowers it has ever been my good fortune to see, namely, a large field whose surface was a blaze of colour, varying from deep purple almost to white, made by the flowers of the early Orchis, *O. Morio*. I have never seen such a colony of this pretty little Orchis, nor had I any idea that it ever grew so abundantly in our meadows. I have, however, since heard of other similar instances. One often comes across small clumps and groups of Orchis Morio, but to see a large field surface transformed into a sheet of purple was to me a delightful sight, and one impossible to forget. This, in common with some other British Orchises, has a habit of disappearing for a season or two. One may sometimes look in vain for these quaint and interesting flowers where the previous season they were blooming in full beauty. Instances have been known where in two or three seasons, in meadows that annually were a delightful picture when *O. Morio* was in flower, the Orchises were killed outright through the application of manure to the land. I have had no experience in trying to transplant this Orchis from the fields to the garden, but I should think probably that unless given very careful treatment it would soon disappear. Burnham Beeches and the immediate neighbourhood form a happy hunting ground for the wild plant enthusiast. The Butterfly Orchid, the Tway-Blade, *O. latifolia*, *O. maculata*, and others may be found there, while the Bog Bean, Asphodel, Droseras, and other moisture-loving plants abound. A. P. H.

#### RANUNCULUS ACONITIFOLIUS AND ITS DOUBLE VARIETY.

The only white-flowered Ranunculi native to Britain are the interesting species that are so often to be found on the surface of ponds and streams. Of the European kinds, many inhabit mountainous regions, and mostly have white flowers. None is so widely known and

grown as the robust double-flowered variety of the Aconite-leaved Crowfoot, *Ranunculus acontifolius*. The type, called by Gerard *R. alpinus albus*, is not a high alpine plant, but, growing at lower altitudes, mixes and struggles with other tall vegetation, and, coming to this country with a robust constitution, it thrives very well in places where the smaller species would speedily die out.

The wild form of this pretty plant sends up numerous stems, bearing a profusion of small white flowers. These soon fall off; hence the plant is of little use for cutting. By many the single-flowered is considered unworthy of a place, but a waterside planting is effective. The wild form is not a common garden plant, and in some places it declines greatly in strength in a way that never

happens under similar circumstances with the fine double variety. The seeds, which are borne in quantity, may weaken it, but, judging from the effects of seeding on other Ranunculi, this should not be. The double-flowered variety, with blossoms as full as a miniature double Dahlia, is often seen growing well in gardens rich in fine old plants. The names of Fair Maids of France, Fair Maids of Kent, and White Bachelor's Buttons all tell of its popularity. *Ranunculus acontifolius flore-pleno* probably originated as a garden sport. At all events it existed in quantities in English gardens during and probably long before the sixteenth century, as Gerard, writing in 1597, says: "It groweth in the gardens of Herbarists and lovers of strange plants, whereof we have good plenty, for it groweth not wild anywhere." The last phrase hints at its origin. Often double forms occur in cultivation, although there are many exceptions. In habit this double form surpasses the wild plant, for the flowering stems are very compact and admirably adapted for cutting. The flowers produced in May and June last several weeks in full beauty. In dry soils these plants are not a success. The stems are stunted, the flowers poor, and the leaves frequently destroyed by the borings of an insect, similar in effect to the Marguerite pest. The roots are strong, and can well penetrate a moist clayey ground. The illustrations show both the wild and cultivated plants, but little removed from the water's brink. For an increase, divide the clumps when the leaves begin to fade in summer. D. S. FISU.

*Royal Botanic Garden, Edinburgh.*

#### WILD PINKS,

(Continued from page 6.)

B.—*D. ARMERIA* (the Deptford Pink) is an annual or biennial species, freely reproducing itself from self-sown seed. Generally found growing wild on dry banks or gravelly pas-

DOUBLE VARIETY (*RANUNCULUS ACONITIFOLIUS FLORE-PLENO*) BY WATER.

tures, it has a wide distribution, being spread over a great part of Europe and extending into Western Asia. It is also naturalised in some parts of the United States. Self-sown seedlings form a rosette of short, broad green leaves the first year, from which the branching stems, 2 feet high, are produced in the following spring bearing loose cymes of red flowers, dotted with dark spots, in July and August.

**D. BARBATUS** (the Sweet William) is an inhabitant of the mountain meadows of South and Eastern Europe, and was introduced into cultivation over three centuries ago. Growing from 1 foot to 2 feet high, with broad green leaves, the bearded red flowers marked with a zone near the base of the petals are produced in large, loose heads in summer. One of the most useful and popular of hardy biennials we have; a good border plant of easy culture and good constitution. It has been considerably improved of late years, numerous varieties having been gained with flowers of various shades of colour, far surpassing the wild plant in size and beauty. Double forms are sometimes grown, but are somewhat heavy in appearance and lack the beauty of the single kinds. *D. b. latifolius* is a form with broader leaves and trusses of larger rich crimson flowers; a plant of great beauty.

**D. SEGUIERI**.—A freely branching, erect plant, generally found on grassy hills and amongst mountain thickets in South and Eastern Europe, 1 foot to 2 feet high. The rosy purple flowers are borne in loose heads, sometimes solitary, on short peduncles in summer. In cultivation since 1832.

**D. ALPINUS** (the Alpine Pink) is a beautiful little plant, and may be considered one of the gems of the rock garden. Composed of a tuft of blunt-pointed, shining green leaves, it is at once distinguished from all other species by this character. In poor soil it is very dwarf, producing its large, deep rose-coloured flowers, spotted with crimson, freely. These are borne singly on short peduncles, but when planted in richer soil the plant has a tendency to grow taller and produce more than one flower on a stem. An open situation suits this plant, in gritty soil to which a proportion of lime rubble has been added. It may be increased by means of cuttings, but comes quite true from seed. Flowering in June, this pretty little Pink is found very high up on the alps of Austria and Central Europe growing on calcareous rocks. Introduced in 1759.

**D. BREVICAULIS**.—A very compact little plant, woody at the base, with very short branches and numerous pink flowers borne singly on short stems, so freely produced as to quite cover the foliage. The whole plant is only about 2 inches high, and is suitable for planting in crevices where the roots can penetrate. A native of the alpine region of the Taurus, in Cilicia; it flowers from July to September.

**D. CAESIUS** (the Cheddar Pink) is one of the most useful plants for the rock garden; at once neat and pretty, forming large tufts of

glaucous foliage, a permanent carpet all the year round. The rose-coloured fragrant flowers are freely produced in summer. Of this species there are different forms, some having large flowers borne singly on short stems, whilst others grow taller and have branching stems with two or three flowers. The petals are pubescent and have erenate margins. A native of Europe; it is also found in this country on the Cheddar Rocks in Somerset. Equally at home on ledges in the rock garden or in the ordinary border raised a bit above the level with brickrubbish, it is proof against the damp of our winters.

**D. CALLIZONUS**.—A native of the Transylvanian Alps, growing on calcareous rocks at an elevation of 6,000 feet to 7,000

to 4 inches high. Seeds do not ripen freely, but cuttings root readily in summer, and should be kept in a north frame till planted out. Introduced in 1889.

**D. CARYOPHYLLUS** (Carnation, Clove Pink).—The wild Carnation is a much branched glaucous perennial, found in various parts of Europe growing on rocks and ruined walls. It is also found naturalised in parts of this country on the old stone walls of Rochester and other castles, sending down its long, slender roots among the mortar in the cracks between the stones. The flowers of the wild plant vary in colour, with broad, beardless petals. The origin of the garden Carnation, innumerable varieties of great garden value have been derived from this species.

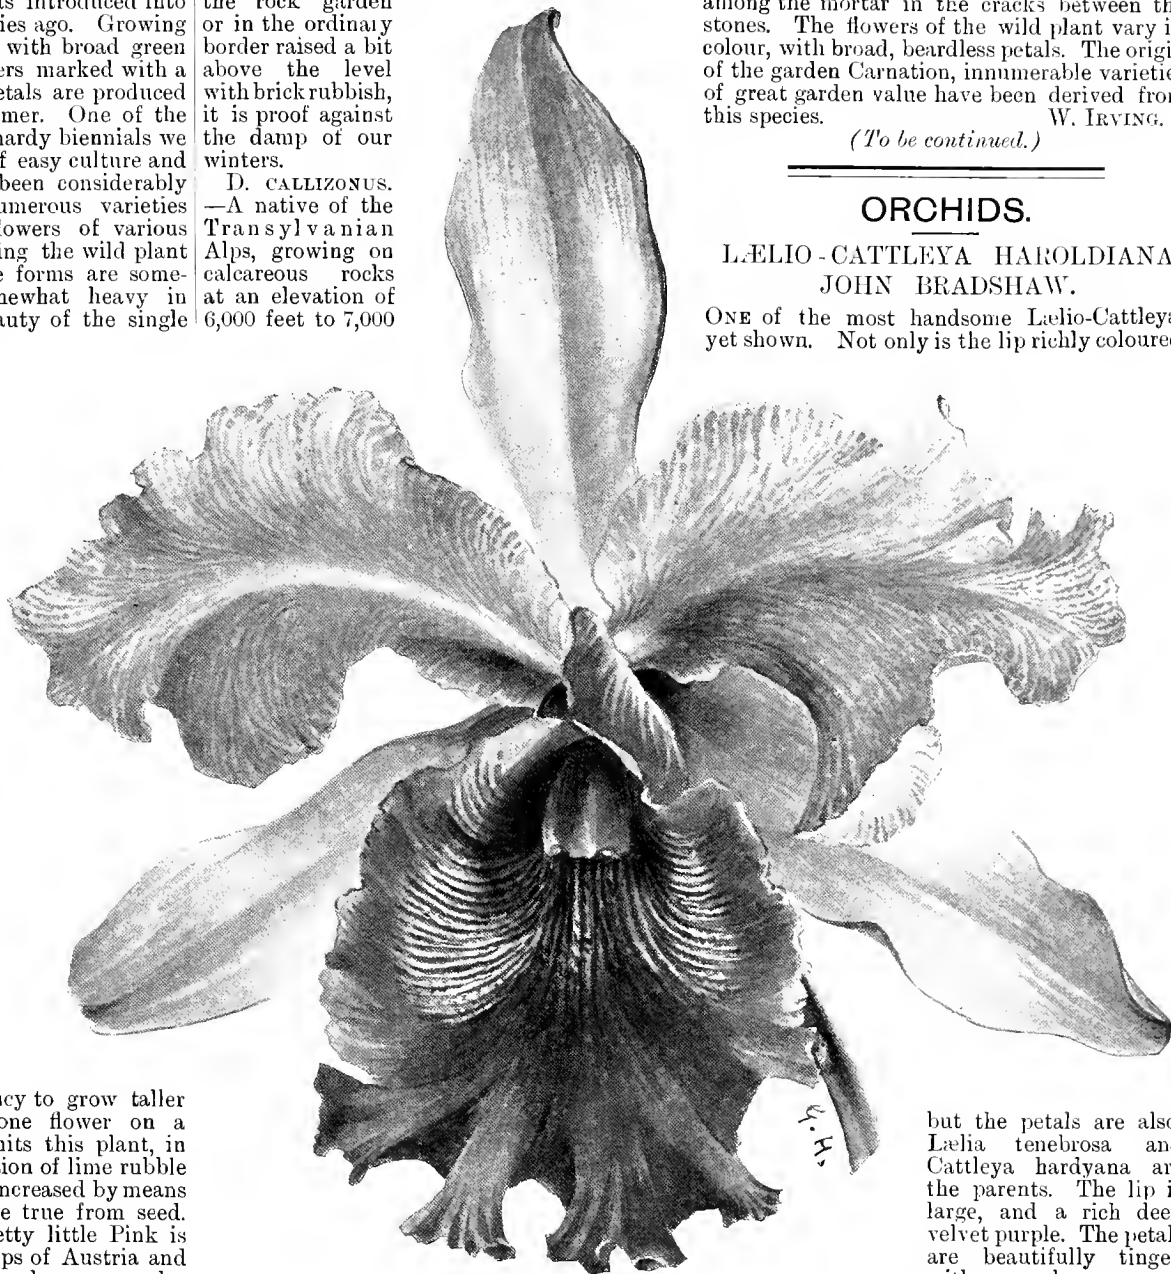

W. IRVING.

(To be continued.)

## ORCHIDS.

LÆLIO-CATTLEYA HAROLDIANA  
JOHN BRADSHAW.

ONE of the most handsome Lælio-Cattleyas yet shown. Not only is the lip richly coloured,

LÆLIO-CATTLEYA HAROLDIANA JOHN BRADSHAW. (Natural size.)

but the petals are also. *Lælia tenebrosa* and *Cattleya hardyana* are the parents. The lip is large, and a rich deep velvet purple. The petals are beautifully tinged with purple upon a buff-yellow ground; the yellow sepals are faintly tinged with purple also.

feet. Many growers have found this lovely little plant difficult to establish. One of the most essential conditions for its successful culture is almost total shade. It should be planted in gritty soil in a position facing west, where the overhanging branches of a small shrub protect it from the sun. Under these conditions it grows luxuriously at Kew, producing its beautiful flowers freely from June to August. These are pink, with a purple, white-dotted zone, 1½ inches in diameter, solitary on stems 3 inches

It was exhibited by John Bradshaw, Esq. (gardener, Mr. G. Whitelegge), The Grange, Southgate, N., recently before the Royal Horticultural Society, and was given a first-class certificate. Of all the forms of *Lælio-Cattleya* exhibited last year before the Royal Horticultural Society, *L.-C. haroldiana* John Bradshaw must certainly be accounted one of the most beautiful, both with regard to the shape of the flowers and their colouring. It is a great gain.

## NOTABLE GARDENS.

### SUMMER FLOWERS AT HALTON.

HINTS FOR 1904.

**T**HE past summer was more unfavourable to general gardening operations than any previous recorded season, therefore there need be little wonder that in many places outdoor decorative gardening has resulted in more or less serious disappointment. Where the now almost obsolete style of flower gardening is still adhered to, viz., beds more or less formal in arrangement, and planted with zonal or tricolor Pelargoniums, Calceolarias, Ageratums, Lobelia speciosa, Gazanias, and other plants of similar character, the results, particularly during June, July, and onward to the middle of August, were most disappointing. A sun-loving plant like the zonal Pelargonium for instance, so frequently found occupying one-half, or even three parts of the area of our parterres and flower-beds, was last season an object of commiseration, if not even of scorn, and the others named fared quite as badly.

In modern gardens we find that the proprietors and their gardeners are each, according to their individual tastes and the adaptability and character of their gardens, devising and adopting different methods of treatment for the summer decoration of terraces, beds, and borders. In the beautifully laid out and well-kept grounds of Alfred de Rothschild, Esq., at Halton, situated on a north-western slope of the Chiltern Hills, and close to the Hertfordshire border of the county of Bucks, a departure has been made, which bids fair to effect a great change, both in the plants used and in the manner of treating them for outdoor gardening. Mr. de Rothschild, I was informed, is deeply interested in the management of this portion of his domain, and as is well known he is endowed with an intense appreciation of the beautiful in the world of Art, and in the arrangement and embellishment of his garden and grounds his gardener doubtless receives many valuable lessons. The departure here adopted consists of interspersing Palms, tropical foliage, and flowers among the shrubs, and also of forming a series of borders on the front of the shrubberies facing the mansion, the terrace, and principal paths. In the most prominent positions are placed specimen *Chamærops*, *Phoenix*, and *Raphis*; tall plants of *Dracæna australis*; finely-grown standards of *Acer Negundo variegatum* are placed in certain advantageous positions, and show their bright foliage through the higher banks of shrubs. Nearer the ground line are well-shaped plants of *Golden Retinospora*, *Golden Privet*, and the best forms of variegated *Cornus*; these are placed at intervals to form a setting for the flowering and foliage plants arranged immediately in front. The most striking feature, however, are the large baskets of Ivy-leaf *Geraniums* and *Fuchsias* 3 feet across, and elevated by a special arrangement among the shrubs to heights varying from 5 feet to 15 feet above the ground. These are arranged in such a manner that the baskets themselves are not in view; they are all well filled with strong plants, which droop 2 feet to 3 feet or 4 feet, and furnish the front of the shrubberies with a grand display of flowers, the effect being unique.

There are from 150 to 200 of these baskets, two-thirds of them being filled with Ivy-leaved *Geraniums*, the varieties *Galilee* and *Mme. Crousse*, of a light and deep shade of pink respectively. The *Fuchsia* baskets are arranged chiefly at lower elevations than the *Geraniums*, and come into line with the plants furnishing the borders immediately in front. The varieties of *Fuchsias* are confined to those having light-coloured sepals and petals, and include *Ballet Girl*, *Lady Heytesbury*, *Mrs. Marshall*, &c., all of which luxuriated in the close, dull showery weather prevailing during the summer. They were a perfect sheet of bloom, and apparently were quite happy under the prevailing conditions. The borders in front, in which are placed *Retinosporas* and other golden foliaged shrubs, are filled in with groups of various plants. *Pyramidal Fuchsias*, chiefly of the variety *Ballet Girl*, 4 feet or 5 feet high, occupy prominent

positions; then are groups of *Acalypha McFeeana*, *Anthericum Liliastrium variegatum*, and *Abutilon Thomsonii*. These are arranged pleasingly, and are fronted by groups of tuberous *Begonias*, all of a soft shade of pink; with these are groups of *Begonias* of the *semperflorens* section, such as *Sutton's Fairy Queen*. These again are edged with borders of varying width (there is no formality in this arrangement), and are planted with *Opbiopogon spicatum foliis variegatis*, with alternate patches of *Abutilon vexillarium*, the ground generally being carpeted with *Nepeta Glechoma variegata*, which is a very neat plant for this purpose. This gives a perfect finish to the grouping, which, at the time of my visit, on September 3, presented the most perfectly finished and harmonious arrangement that I have seen, every group of plants appeared quite at home, having defied both deluge and gales; freshness of foliage and profusion of bloom were in evidence at every point.

There were other beds, some few of which were planted in the stereotyped fashion, but more important beds were raised several feet above the turf; these were planted with irregularly shaped clumps or groups of foliage plants, alternating with groups of flowering plants of equal height, large masses of variegated *Phlox* contrasting with the bold bronze foliage of *Cannas*. Groups of variously coloured *Begonias*, *Coleus*, *Centaureas*, and *Salvias* added to the striking appearance of these large beds. As to any local advantages which may contribute to this pleasing, and to me unique, style of gardening, I have to confess that I could not discover them. The situation is high, and the garden is much exposed to the west and north-west, in which directions extensive views are obtained over *Wendover*, *Coombe Hill* (where has been erected the county's memorial to the Bucks men who fell in the Boer war), *Kimble*, *Bledlow*, and away across *Oxfordshire*, and to the north-west, some 10 miles distant, *Waddesdon Manor* is visible. The soil at Halton is very poor, being almost on the bare chalk. The shrubberies are planted thickly for the purpose of shelter, and notwithstanding the unfavourable conditions of exposure and poverty of soil are thriving well. This wonderful transformation is due to the exceptional taste and knowledge of Mr. de Rothschild, and to the skill of his gardener. J. J.

[The publication of this article has been unavoidably delayed.—Ed.]

## CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

### INSTRUCTION FOR YOUNG GARDENERS.

[TO THE EDITOR OF "THE GARDEN."]

**S**IR,—I was glad to see a note in a recent number of *THE GARDEN* upon this subject. An instance was given of a head gardener having commenced a weekly class for the benefit of the young men working under him. I consider this to be by far the best way of endeavouring to improve the minds of young gardeners, and so to raise the status of this worthy body of men and to improve their conditions, such work as this goes to the root of the whole matter. Improve the minds of the future generation of head gardeners, and see that they learn something of the science as well as the practice of horticulture, such a training cannot fail to have a beneficial effect and bring to bear a more intelligent and enlightened application. In saying this I do not in the least wish to depreciate the good work done by many head gardeners of to-day; I refer simply to gardening and gardeners generally, and not individually. If young gardeners are given opportunities of gaining knowledge which their masters never had, and take advantage of them, then the status of both gardening and gardeners will rise as a matter of course, and an improvement in their conditions will inevitably result.

We have heard a good deal lately about the proposed Gardeners' Association, and many have expressed doubts as to the real good such an association can do. People talk glibly of improving the condition of gardeners and raising the standard of gardening as though it can be done by following the methods of trade unions. But all such efforts are in my opinion foredoomed to failure. There must be a radical change, such as can be brought about only by influencing gardeners when they are young, and it seems to me that a Gardeners' Association might take this matter up and do very valuable work in this direction. There is no doubt that horticulture is being more and more recognised every year as a most important industry. While agriculture has lost ground, horticulture has progressed by leaps and bounds, until at last even the Government is waking up to the immense importance of one branch of it, namely, fruit culture, and has appointed a Commission to enquire into the present conditions of, and to consider what measures may be adopted to improve this industry.

This instance simply serves to show how essential it is that the rising generation of gardeners shall be thoroughly and intelligently trained, and if the proposed association can do something towards bringing this about it will have begun a work that in the end is bound to bring its own reward. I do not venture here to suggest how this may be done, but I do believe that the only real and lasting good the Gardeners' Association can do to the profession is thoroughly and technically to educate it. It is all very well to say that so long as a gardener knows how to grow fruits, flowers, and vegetables he is able to give his employer satisfaction. So he may, but as long as gardeners continue to retain this spirit it will be very difficult to raise their status. The old order of things is passing away; owners of gardens are realising more and more the possibilities of their gardens, and it behoves the gardener to realise and to master them also.

Indirectly, the question of improving the knowledge and widening the ideas of gardeners affects their wages. As I have just mentioned, employers now require much more of their head gardener than was the case ten years or fifteen years ago, and the standard of requirement is likely still to be raised. They therefore will not be satisfied with a gardener whose knowledge of his calling is confined to the production of fruits, vegetables, and ordinary as to the best colour-schemes for flower borders, the flowers; they will require one who can advise them arrangement of rock gardens, the proper care of alpine plants, intelligent pruning of fruit trees, and other items. Men accomplished in what may be termed the finer side of gardening will be sought after, and they will in consequence demand higher wages. I have probably written too long on this subject, however, so will conclude with the hope that the new Gardeners' Association may not lose sight of what I believe to be the most important factor in raising the standard of gardening and gardeners, namely, general and technical education. HORTUS.

## BOOKS.

**Lays and Lyrics from the German Poets.\***—The translator has compiled a little volume of verses, transposed from the German, of considerable charm, if of rather unequal merit. The little "Song" of Rückert's, "Heaven's Tear," is altogether delightful; the quaint fancy has been expressed with tenderness, grace, and a spontaneousness which is, perhaps, a little lacking in some, but here leaves nothing to be desired. Other verses seeming to call for special notice are "May Time" (Julius Rodenberg) and the "Lament" from Heine. Perhaps the opening verse of this little volume is scarcely happily chosen—a verse from Heine, of which "Sydney Hesselrigge" hardly seems to have caught the charm and delicacy. We cannot help recalling the same lines translated by Mr. Ernest Radford in "Chambers Swain" (Elkin Matthews), under the title of the

\* "Lays and Lyrics from the German Poets." Translated by Sydney Hesselrigge. Henry B. Saxon, Nottingham.

opening lines, "Thou art like unto a flower." However, this hardly detracts from the volume on the whole, and the wee book, dainty in size and well printed, will give great pleasure to many lovers of verse.

"HEAVEN'S TEAR.

"The heavens let fall a limpid tear,  
Which thought 'twould be lost in the ocean drear;  
But a sea-shell caught it and held it tight,  
Saying, 'Now thou art mine, O pearl so white!  
So be not afraid midst the raging storm,  
For I will carry thee safe and warm.'  
O! sky-born tear within my breast,  
Thou form'st my joy, yet my unrest.  
Grant, Heaven, that I in faith and love  
May guard thy tear-drop from above."  
(Song IV. from Rückert's "Liebes Frühling.")

MISCELLANEOUS.

THE ROYAL HORTICULTURAL SOCIETY OF SOUTHAMPTON.

IN 1862 this society was established under the title of "The Southampton Amateur Horticultural Society." A few amateurs, with one or two horticultural friends, met in the December of that year and elected a committee to work up members and draw up a schedule of prizes. Of that committee only two are still living—Mr. Miles and Mr. Slight. Subscriptions did not come in very fast, but, not discouraged, the committee, with Major Lacy as chairman, issued a schedule, in which the majority of the prizes consisted only of cards and certificates, and a capital little show was held on June 29, 1863, under the patronage of the Lord Mayor of London, the first president being Sir Edward Hulse, Bart., and the secretary Mr. Alexander Kelly. In 1864 the word "Amateur" was dropped from the title. In 1865 Lord Palmerston accepted the presidency, and in 1866 Thomas Chamberlayne, Esq., of Cranbury Park, became the president, an office which he retained until his death in 1877. In this year (1866) we find amongst the committee the names of Mr. A. Dean and Mr. C. S. Fudge. The latter soon found favour as a worker, and to him and Mr. Windebank, sen.—the head of the well-known nursery firm of that time—were entrusted for several years the staging arrangements for the shows. At this time the society seemed inclined to run before it could walk, with the result that a debt of £45 was incurred, a debt which was not fully paid off until 1872. In 1872 the first spring show was held, and in this year Mr. Fudge was appointed superintendent of the shows and chairman of the finance committee. The satisfaction which he gave in those positions resulted in his election at the end of the year to the position of secretary. Mr. Fudge at once set to work to increase the membership, which at that time consisted of only 160 subscribers. No less than 350 new subscribers were added in the next two years. From this time the society advanced by leaps and bounds, the shows ever increasing in importance and popularity. In 1877, at the instance of Captain Gibbs, a member of the committee, a small Chrysanthemum show was held in connexion with the annual meeting, the blooms then exhibited being mostly reflexed varieties.

The first open Chrysanthemum show was held in 1878 in conjunction with a cage bird show. This show proved so popular that it has been continued, with three notable exceptions, ever since, always growing in extent and importance; the bird shows ceased after 1889, all the space being required for the horticultural exhibits. It was at the early Chrysanthemum shows of this society that Mr. E. Molyneux made his reputation as a Chrysanthemum grower. The same remark applies in a lesser degree to Mr. Flight of Winchester, Messrs. W. and H. Drover of Fareham, Mr. Penfold of Leigh Park Gardens, Mr. Wills, and others who, in the eighties and early nineties, made a name in the Chrysanthemum world.

The year 1879 was a very important one. The Hon. E. C. Yorke had only been re-elected president about three weeks when he was taken suddenly ill and died a few hours after. It was entirely due

to the great respect in which the deceased gentleman was held by the Royal Family that H. R. H. Prince Leopold was induced to fill the vacant presidency for that year, and that Her Majesty Queen Victoria forwarded, through the Secretary of State, Her Majesty's commands that the Society should in future be styled the Southampton Royal Horticultural Society.

About this time General Lacy, with the object of securing a permanent home for the society, and to save from the builders a very beautiful part of Banister Park, initiated a scheme to incorporate the society under the Limited Liability Act, to be called the Royal Horticultural Society and Gardens, Limited. Three thousand pounds' worth of shares were applied for, directors appointed, the articles of association drawn up, and a draft lease for 999 years submitted, but the whole matter was wrecked over one clause insisted on by the lessor, requiring that the grounds should be laid out, a winter garden built, and all necessary glass houses and other buildings completed in three years—a responsibility no one would face. From 1879 to 1882 the society continued to prosper under the

MR. C. S. FUDGE.

(Secretary since 1872 of the Royal Horticultural Society of Southampton.)

presidency of Hans Sloane Stanley, Esq., of Paultons, Romsey. Unfortunately at this time both the Banister Park and Westwood estates, where the shows had been previously held, were being laid out for building purposes. However, the owner of Westwood came forward with an offer to lease to the society ten acres for fourteen years upon certain conditions. After considerable negotiations trustees were appointed to act as lessees, the lease was signed, and £1,000 raised by the issue of £5 ivory tickets giving certain privileges of admission, &c. The land was handed over to the society in March, 1883, and a start made to enclose the site and erect entrance lodge, store, &c.

The society this year (1883) had the honour of being presided over by H. S. H. Prince Edward of Saxe-Weimar, who, with the Princess of Saxe-Weimar, attended to open the society's grounds on June 28, the grand exhibition of the National Rose Society being the great attraction. The unprecedented number of nearly 300 new members was added to the society this year, but, notwithstanding this and the fact that the great floral fête and the autumn shows were unqualified successes, the council of the society found themselves faced with a deficit of over £300.

However, the tenancy of this ground will be long remembered by horticulturists for the series of grand shows held there, the like of which will probably never be seen again south of Shrewsbury. The most successful probably was that held in 1886, which was opened by H. R. H. Princess Henry of Battenberg, accompanied by Prince Henry. On that occasion over 23,000 paid for admission, in addition to the 3,000 tickets issued to members.

In 1889 the council had to begin the year with a debt of £160, caused by carrying out certain obligations under the lease; it was therefore resolved, against the advice of the secretary, to do away with the autumn show, a disastrous policy, as it turned out, resulting in many members withdrawing their subscriptions; and it was only when these shows were regularly reinstated in 1893 that the withdrawals were stopped. The late Mr. W. H. Rogers, of the Red Lodge Nurseries, was this year elected chairman of the council, and it was largely due to his influence, and steadfast opposition to the unreasonable demands of the lessor, that the society steered clear of the many difficulties that beset it at that time. From 1884 to 1889 the office of president was held successively by the Hon. H. Crichton, the Right Hon. Lord Montagu, and W. H. Myers, Esq. In 1890 Sir Samuel Montagu, Bart., was elected to that office, and he has presided over the society ever since.

In March, 1897, the lease of Westwood Park came to an end, when the society found itself without a home, the buildings and stock-in-trade mortgaged, and with a debt of nearly £350, a considerable portion of this amount being the balance due on the Cinder Track loan. Not daunted, the council set to work to relieve themselves of these difficulties. The bank advanced the money to pay off the mortgage, so that the material required for future shows was saved, and the sale of the remainder, fence, buildings, &c., realised sufficient to meet most of the other liabilities.

The summer show and fête this year was held by permission of the Corporation on the Southampton Common; but the great expense of temporarily enclosing the site resulted in another loss, so that at the end of the year the society was still £140 in debt. To meet this the secretary suggested that £5 bonds should be issued, bearing 5 per cent. interest. The bonds were readily taken up, and another start was made; but no place suitable being available, the great floral fêtes had to be given up altogether. In its place it was decided to try a spring show and an early summer and Rose show, the latter to be held on the Southampton Pier. So successful has this policy been that the subscription list has been well maintained, and by the aid of several garden parties at South Stoneham House grounds, kindly lent by the president, the whole of the bonds were redeemed by the end of last year, the society is free of all liabilities, and has a balance at the bank of nearly £100.

GARDENING OF THE WEEK.

FLOWER GARDEN.

RECENTLY PLANTED SHRUBS.

PERIODICAL inspection should be made of all newly-planted specimen trees and shrubs to see that the ties or stakes do not chafe the bark. If not already done a good mulching should be given.

For this purpose nothing is better than Nature's covering—leaves; where they are likely to blow about a thin coating of soil will keep them in place.

AQUATICS.

During severe frosts Nymphæas and other aquatics should have quite a foot of water over their crowns. Where they are grown in cement or slate tanks the ice should be broken daily, as there is considerable danger of such structures being cracked. The smaller growing Nymphæas, such as N. pygmaea, N. Helvola, N. odorata, &c., are sometimes grown with great effect in tubs sunk in the ground, and, although they are hardly, it is wise to

place some covering over the tubs during severe weather. Where Nymphæas are grown in ponds and lakes a look out should be kept for water rats. These creatures are very fond of the roots, and if not checked will quickly spoil a valuable collection.

#### PRUNING EVERGREENS.

If a severe cutting back of such evergreens as Aucuba, Box, Laurel, Yew, &c., is necessary, it is better to delay the operation until April or May, when the shrubs will soon recover. Providing the labour is sufficient the pruning of Laurels and kindred shrubs should be done with the knife in preference to cutting with hooks: but in many places time does not permit of this. Before commencing the operator should first close up any gaps by tying in the neighbouring branches. All green shoots found amongst such shrubs as the golden and variegated Euonymus, &c., should be persistently cut out, or they will take the lead and soon outgrow the more decorative portion.

#### PRUNING CLEMATIS.

These climbers may now be dealt with. Clematis flammula, C. montana, and such as flower on the last season's growth should be pruned sparingly. The object of the pruner should be merely to remove all weak and dead growths, and to lay in a good quantity of strong growths for flowering. Where there is only a restricted space to be filled by the Jackmanii type this section may be cut almost to the ground; but if the object is to cover a verandah, a large amount of trellis work, or a tree stump it will be well only to cut down part of the stems, or there will be a considerable bare space during the spring and early summer. Hard pruned Clematis will flower somewhat later than those but lightly pruned. A. C. BARTLETT.

*Pencarrow Gardens, Bodmin.*

#### INDOOR GARDEN.

##### ORNAMENTAL ASPARAGUS.

AN effort to repot those plants required to make large specimens should be made early, and attention to increasing the stock of plants should be given by way of splitting up others into small portions, remembering that a portion of root must be attached to each piece. For growing in baskets suspended from the roof nothing can equal A. Sprengeri, and when put into large pots and afterwards grown on stools or stands from 4 feet to 5 feet in height the plants will soon become objects of much beauty. A compost of two-thirds fibrous loam, one of peat, with a small proportion of sand and charcoal added appears to suit them well. Raising these plants from seeds is not difficult, and a good plan is to obtain turves, place the grass side down, and cut them into pieces 2 inches square. Scoop out a portion of the soil of each square to form a hollow place, and fill this with a light sandy compost. Three seeds are quite enough to sow on each square, and place them closely together afterwards in a shallow box. Finally, cover the whole over with sand, and after affording them water from a fine rosed can place in a close temperature of 70° to 75°.

##### FERNS.

Beyond a few plants of Adiantum cuneatum—previously introduced to warmth and moisture to encourage growth and to provide a few green fronds for use in a cut state—these plants generally will still be resting. Preparations for repotting those that require it should be pressed forward, and opportunity be afforded, as the days increase in length, for increasing the temperature as well as the supply of moisture to start them into growth. The compost for Ferns should consist chiefly of peat, fibrous loam only being added to suit the requirements of strong-rooted sorts, and in every instance being used with great consideration. Filmy Ferns at all times delight in a close, moist atmosphere, and among the peat, which should be lumpy, that is used for repotting or resurfacing mix large pieces of sandstone and charcoal.

##### PROPAGATING.

Many Croton plants, which during the autumn, through constant use upon the dinner-table, lose

their leaves and become leggy, should be "ringed." To do this remove the bark about half an inch deep and for quite three-quarters of the circumference of the stem, otherwise notch, i.e., cut out a portion of the stem about halfway through and at a point near the leaves. Around the cut parts bind Moss tightly to exclude the air, and keep this moist by frequent syringing. Afford the plants a close moist atmosphere and a temperature of 70° to 75° to encourage the formation of roots.

##### CALADIUMS.

Generally speaking, none too many of these bulbs are preserved through the winter in good condition, so it is advisable to overhaul the stock at once, and by way of increasing it cut into pieces those bulbs which have two or more crowns, taking care that each portion possesses a crown. After dusting well the cut portions with powdered charcoal, arrange the bulbs in shallow boxes amongst cocoa fibre or sifted leaf-soil, and place them in a temperature of 65° to 70°, where they will soon commence to root.

##### PANDANUS VEITCHII.

At the base of nearly every one of these plants are to be found suckers. It is the weakest of these that should be selected for propagating, as they are generally the best coloured, and eventually grow into the neatest and best table plants. Insert them around the sides of 3-inch pots in sifted leaf-soil and sand and plunge in a bottom-heat of 80°.

J. P. LEADBETTER.

*Tranby Croft Gardens, Hudd.*

#### FRUIT GARDEN.

##### POT VINES

whose fruit is set will take liberal supplies of liquid manure water. A rich top-dressing of good fibrous turf, with a little Thompson's Vine Manure added, will be of great assistance to them, repeating this when they are well rooted. Keep a night temperature of 68°, reducing it to 65° on very cold nights and when the berries are stoning. Pay every attention to watering and the stopping of laterals, two or three leaves beyond the bunch if space allows. Do not syringe the fruit when swelling, but syringe the walls and damp the paths. Avoid very hot pipes when the nights are very cold. From

##### PLANTED-OUT VINES

started early last month remove all the weaker shoots, and select later those which promise best for fruit. Encourage a free growth, and do not be in a hurry to tie down the shoots, except those which press against the glass. Stop all shoots two or three leaves beyond the bunch, giving each lateral plenty of space. When the Vines are in flower more air must be admitted and a drier atmosphere kept. Examine the border when the Vines have gone out of flower, and if dry water with weak liquid manure or clear water. Top-dress the border with short manure, and encourage the roots to the surface; avoid heavy dressing at one time, as this excludes the air.

##### SUCCESSION VINERIES.

If the excellent advice given in recent numbers of THE GARDEN has been followed, the houses and Vines will have been thoroughly washed and painted, and the borders top-dressed. To have ripe Grapes in June and July they should now be started at a temperature of 48°. If young Vines, they will break more evenly if the ends are tied along the front of the house. The border should be examined and well watered with warm water if dry. Syringe the Vines two or three times daily, and damp the house according to the weather, keeping the evaporating pans filled. It is always safe to allow the temperature to fall on very cold nights, and force during the day with sun-heat by closing early on all favourable occasions.

##### LATE VINERIES.

Nothing will now be gained by allowing the Grapes to hang on the Vines. The Grape room should be prepared for them, and the bottles filled with soft water. Choose a fine dry day, and cut the bunches with all the wood above and below the bunch. Examine them occasionally for any

decayed berries, and keep a temperature of 43° to 45°. Prune the Vines, cutting to a plump bud with a sharp knife; the next day dress the wounds with Thompson's Styptic. Wash the house and give one coat of paint, clean all loose bark of the Vines, dressing them with Gishurst Compound. Top-dress the borders with loam, wood ashes, and some approved Vine manure.

Vine eyes to the number required should now be put in. The wood should be firm and well ripened. Cut off a little wood below the bud and put in small pots filled with loam and sharp sand. Keep the bud level with the soil and make firm in the pot. Water lightly and plunge in a bottom-heat of 80°.

#### KITCHEN GARDEN.

##### THE SEED ORDER.

NURSERYMEN, ever mindful of the gardener's needs, are now sending their lists, and I would here repeat the advice they give—"to order early." This is a distinct gain to the gardener and a kindness to the seedsmen. The aim should be—first, to select old, well-tried varieties suitable to the district; and, secondly, a few novelties should be grown, as these give an additional interest to the garden. Some will be worthless, and others will be real advances on existing sorts. An inspection of all seeds left over from last year ought to be made. Such seeds as Lettuce, Peas, Radish, Turnip, and almost all the Brassica family will keep good for several years and give satisfactory results. It is well to test any variety that looks doubtful by counting out a certain number of seeds, and sowing them in pots in a gentle heat.

##### EARLY POTATOES.

A start should now be made with the earliest batch of Potatoes in pots. Sharpe's Victor or Sutton's May Queen are two of the most suitable varieties for this purpose. The tubers should be placed in shallow boxes and given a genial warmth to start them. The eyes should be reduced to two of the strongest. The most suitable soil is a turfy loam, to which have been added some manure from an old Mushroom bed and some leaf-mould. The pots should be 9 inches in diameter, clean, and the drainage ample; they ought to be half filled with the compost only to allow a dressing to be given later. The pots should be placed along the front of a vinery about to be started, as this is an ideal place for them.

##### EARLY PEAS IN POTS.

Where accommodation is available this is always a much-prized vegetable, and, where about 400 pots can be fruited, many good dishes can be had. Several sorts are recommended for this work that are the reverse of suitable. Chelsea Gem, Hurlbinger, and that old variety American Wonder are three of proved merit; 8-inch pots will be found to be the correct thing, and the soil something like that recommended for Potatoes. Care must be taken to start them in a cool house or frame, and to grow them hardy. The first batch should be sown now, and a few notes will be given in future calendars as to management.

##### FRENCH BEANS.

A good sowing should be made now, for as the days lengthen these will fruit much better. The pots should be 7 inches in diameter, and three-quarters filled with the compost as advised for Peas. The most suitable variety known to the writer is Veitch's Forcing Favourite. Sow eight Beans in each pot, which may be reduced to five of the strongest. If possible, these should be placed on a shelf near to the glass in the forcing house and kept out of vineries, as it is impossible to keep them free from red spider. As the plants begin to set fruit they will be much benefited by weak applications of liquid manure.

##### MUSTARD AND CRESS.

Sow in boxes every ten days. Press the seeds well into the soil and keep dark till germination takes place. Place in full light as near to the glass as possible in a temperature of 60°.

THOMAS HAY.

*Hopetoun House Gardens, N.B.*

ORCHIDS.

It is absolutely necessary that all plants in the various Orchid houses should be thoroughly cleaned before the end of this month, otherwise, speaking generally, sufficient time cannot be found when repotting, &c., commences to give them that thorough overhaul which is of great importance to their well-being.

INSECT PESTS.

The most difficult insect we have to contend with in the Orchid houses is the small white scale that infests *Laelias*, *Cattleyas*, &c. It conceals itself under the sheath-like covering of the pseudo-bulbs and around the dormant eyes. Very often a workman in cleaning a batch of plants thus infected unknowingly spreads the pest instead of eradicating it. Nothing is worse than to attempt to remove this pest by means of a pointed stick. Beneath the covering are myriads of eggs; when disturbed dry they are carried to all parts of the house. The best plan is to paint the scale over with methylated spirit and then remove them with a brush dipped in the same spirit—most will then be destroyed; but in addition I would advise that badly

that does not fall below 58°. *C. labiata autumnalis* will require little water to keep them sound, providing the temperature of the house is correct. All hard and fast rules as to watering plants that are resting should be avoided. The points to be observed in the resting season are to retain the solidity of pseudo-bulbs, and to keep the plants dormant till their proper season for further development arrives.

*Gatton Park Gardens, Reigate.*

KITCHEN GARDEN.

GARDEN POTATOES.

(In reply to "B. D. K.")

THOSE seeking for information as to the best varieties of Potatoes for general garden culture may well just now be bewildered when they read day after day in the general Press paragraphs relating to astounding—and, indeed, outrageous—prices paid for certain new Potatoes,

should all be planted, if outdoors, on a sunny border sloping to the south in good soil, and in rows from 24 inches to 30 inches apart. For mid-season or successional varieties capital croppers are Sir J. Ilewelyn, Snowdrop, and Duke of Rothesay (kidneys), and British Queen, Triumph, and Windsor Castle (rounds).

These can be planted in good soil in more open quarters, the rows being not less than 30 inches apart. The late or maincrop varieties are, on the whole, of the chief importance, because these are expected to furnish a supply from November till June. They must of necessity be late ripeners, or otherwise they begin to start too early into growth during the winter. It is still further important that so far as is possible they are robust, free croppers, and have material disease-resisting powers. As these are all strong growers, it is necessary that ample room should be given them, and in good garden soil, that is even more gross than the open field, where light and air are so much more abundant. We always give these strong growers a width between the rows of 36 inches, and the sets in the rows should be fully 16 inches apart. The root produce is invariably greater when ample room for the tops is given. Very fine varieties for late purposes are Up-to-Date, Improved Kidney, Daniel's Special, The Factor, The Crofter, Evergood, The Sirdar, Abundance, and Magnum Bonum; and of coloured varieties the new kidney King Edward VII., a great cropper and fine quality; the Sutton Flourball, red; and The Dean, purple. We have omitted to recommend such new varieties as Northern Star, Eldorado, Discovery, and many others, because where offered in commerce prices are exceptionally high yet, or the varieties may not be on offer at all. The past season was so unfavourable for Potatoes that in many cases varieties of great promise, and of which great expectations were formed, failed to respond, hence there was not that heavy crop anticipated. It has been, therefore, wisely decided to either offer them at practically prohibitive prices or else to hold over the stocks till another year. You will thus see that whilst of older varieties, so far well tested, there are plenty for your purpose, perhaps too many, it is wise to leave quite new ones alone for a year longer, and thus see how far experience will justify expectations.

A. DEAN.

POTATO EARLY PURITAN.

infested plants be removed to a shed while being cleaned. Mealy bug should be eradicated in the same way, and plants that have this dreaded pest on them should be treated weekly till they are thoroughly clean.

RED SPIDER

is often troublesome at this season, when the syringe cannot be freely used, and we have to use strong fire-heat during cold weather. Plants thus infested should be sponged with a thoroughly reliable insecticide; we find a preparation of soft soap, petroleum, and flowers of sulphur very effectual. *Cymbidiums* should be closely examined for this insect. Thrips used to be considered the worst enemy in Orchid houses; but since the introduction of Richards' XL All Vaporiser this pest has been reduced to a minimum. I advise its use periodically, say once a fortnight.

CATTELYAS.

*C. Trianae* and *C. percivaliana* are now commencing to develop their flowers; rather more water should be given. They should be so placed that all available light and sunshine may reach them, maintaining a sweet, buoyant atmosphere

provided, of course, these paragraphs represent the truth, as to which there may well be a difference of opinion. But, true or not, they answer their obvious purpose, which is to encourage weak-minded people to purchase at prices that are a very long way in excess of the real value of any Potato ever put into commerce. In a couple of years, when competition has put prices of these boomed varieties on a proper level, we shall no doubt see, as we have seen with many others that have preceded them, that they are but ordinary varieties after all. We leave those costly follies alone now, and refer only to varieties that have undoubted—because well tested—reputations. In a garden some early varieties should be grown, some for mid-season, and some for late winter use.

If there be desired tubers of the best table quality, mere size and quantity being less a consideration, then good first earlies, whether for pot or box, frame, or warm border culture are—of kidneys, Ashleaf and Ringleader; and of rounds, Harbinger and Sharpe's Victor. If it be desired to have a greater bulk in tubers, then plant White Beauty of Hebron, Early Puritan, and Duke of York (kidneys), or British Premier (round). These

THE INDOOR GARDEN.

SEEDING CHINESE PRIMROSES.

WHILE it is invariably wisest on the part of those who wish to have good forms or varieties of Chinese Primroses to buy seed, it is possible for them to save seed themselves if they have good plants of good varieties. But to induce flowers to seed well, not only should the plants be placed in the light on a shelf where there is ample ventilation and no drip, but the flowers should be gone over with a tiny camel's-hair brush every other day, so as to secure proper fertilisation. On plants that are not so treated the smaller, later blooms will set or produce seed. The results, however, are far from being satisfactory, as few plants seem to be more retrograde than do these fine-bred Chinese Primroses if artificial fertilisation be not resorted to. When it is so resolved to save seed at home, and plants having flowers of diverse colours or markings are put aside for the purpose, a tiny hair brush should be used for each colour. It may be well to have two plants at least of each colour, so as to secure greater interchange of pollen. The maintenance of the fine form of any good variety seems to be largely due to the fact that in this intercrossing each flower is creating seed the product of two plants' strength, whilst where pure self-fertilisation takes place the strength of one plant only is found. All this care is taken by the great seed growers, and it is singularly interesting to find when visiting such a range of houses as those of Messrs. Sutton and Sons, where some 10,000 *Primulas* are grown, how, when placed together, every plant seems to be the reproduc-

tion of its fellows. This remarkable truthfulness to character is entirely the produce of the exceeding care taken in cross-fertilising to keep the brush used to one description of flower only. A year since, when looking over the huge breadths of Chinese Primroses at Reading, it was marvellous to note that so new a variety as *The Duchess*, probably the most distinct and beautiful variety ever raised, should exhibit in probably 1,000 plants, and every one in bloom, scarcely the least diversity in the vast numbers of flowers open. This firm to secure seed do not sow for plant raising earlier than July. They know that the dulness and low temperature of the first two months of the year are not conducive to fertility; but in March and April, when light is good and warmth increases, then pollen is much more freely produced and the results in seed production are all the greater. Naturally, seed growers have rather low but very light, airy, and well-heated houses for seed production. They also keep them comparatively dry, as humidity is not conducive to fertilisation. But amateur seed growers would probably find the semi-doubles, all of which the professional seed growers fertilise so well and seed so admirably, to be beyond their capacity to make reproductive. Few things in floriculture command admiration so much as does the wonderful way in which seed growers develop and maintain high-class Chinese Primroses. A. D.

### NERINE FOTHERGILLI MAJOR AND GLORIOSA SUPERBA ROTH- SCHILDIANA.

THE first is one of the most brilliant of the genus, and is also one of the most commonly grown. When properly managed it makes a showy display at this season, but there are important though simple points in its culture that must be closely attended to if success is to be attained. The fact of its flowering before the foliage has developed is a defect when plants are regarded from a decorative point of view, though the failure, if it may be so termed, can be in a great measure remedied by mixing the plants with suitable Ferns, &c. When its flower-spikes are grown for cutting this defect is not so apparent, as suitable foliage from other plants, such, for instance, as the small leaves of the *Agapanthus*, or fronds of some of the *Pteris* or other Ferns, may be used with pleasing effect.

Its cultural requirements are simple when understood, but failure to flower it in a satisfactory manner may be easily brought about by inattention. We grow a batch of plants in 6-inch pots, which were last potted some years ago, in a compost of rather heavy loam mixed with sand. Though their bulbs and roots are much crowded, we are loth to repot them, and shall not do so so long as they flower freely as they now do. It blossoms best when potbound; but when repotting, and the thinning of bulbs are absolutely necessary, the best time to do this is just before growth commences, and at the same time the stock of plants can be increased by offsets. Our general treatment is carried out as follows: Once growth begins the pots are soaked in a water-tank, and throughout the growing season the plants are not allowed to suffer for want of a plentiful supply of water, with occasional supplies of liquid manure. The plants are syringed overhead daily, except when in flower. Throughout the growing season the plants are fully exposed to the sun upon a shelf placed near the glass in a warm greenhouse. When the foliage begins to change colour water is gradually withheld, and entirely so during the resting season, and the plants are arranged close to the glass in an airy, cool house. The chief cultural points to bear in mind are not to over-pot the plants, to keep them near the glass fully exposed to the sun at all times, except when they are in blossom, supplied with water during the season of growth, and perfectly dry over the resting period.

#### GLORIOSA SUPERBA

is the species commonly met with, but the new and handsome crimson rothschildiana which flowered in Tring Park Gardens this season

promises to be a keen rival if it can be as easily grown and flowered as *G. superba*. The flowers of *G. superba* are both beautiful and peculiar; they are valuable for decorative purposes, and may be used with marked effect for dinner-table decoration. It is necessary, however, when they are used for this and similar purposes, in order to cause the flowers to assume their natural appearance, to bend the foot-stalks. Fortunately, the life of the flower is not appreciably affected by this. As the plants are climbers they should be accommodated with suitable trellises, and if it is desired to move them from one position to another, then make wire trellises in balloon shape; but a better way is to train thinly their growths beneath the glass, over the roof of a warm house, or upon a trellis surrounding a column. We clothe the roof of an *Eucharis* house with this plant, and train the growths in cordon fashion to wires placed at about 2½ feet asunder. This does not appear to affect the *Eucharis* in any way; in fact, only good probably results from the bright summer sunshine being subdued. Of course, during the dull season, the plants having in the meantime died down, the roof is clear and the *Eucharis* have the benefit of full sunshine when it is needed. Grown in this manner in quantity a very pretty effect is secured. The best compost is a good fibrous loam mixed with some peat and sand, and if large plants are required, three or four strong tubers should be placed in a 10-inch or 12-inch pot in early spring before they begin to grow. Water sparingly until free growth has commenced, when give a plentiful supply, and weak liquid manure once a week. The plant is seldom attacked by an insect pest, but nevertheless daily syringings are very beneficial. When it is properly treated its shoots make rapid progress, and require to be frequently secured to their supports and shaded from direct sunshine. As soon as growth ceases, and the flowering season is over, gradually withhold water, and once the foliage turns yellow keep the soil perfectly dry. At this stage the tubers may for convenience sake be taken from their pots, and stored throughout their dormant season in dry soil in small pots or boxes. T. COOMBER.

NEIL SINCLAIR.

## NURSERY GARDENS.

### VEITCH'S WINTER-FLOWERING BEGONIAS.

AMONG plants introduced of recent years, probably none have proved more valuable than the winter-flowering Begonias raised by Messrs. James Veitch and Sons, Limited, of Chelsea. They have undoubtedly been a great boon to many gardeners, both professional and amateur, who value either a supply of cut flowers during the winter months, or who take delight in a greenhouse or conservatory made bright by something other than *Chrysanthemums*. Except *Chrysanthemums* there were really few plants that could be depended upon to produce a show of bright colour at this time of the

year. Zonal *Pelargoniums*, it is true, are most useful, but they are not altogether satisfactory; as cut blooms they do not last long, and the plants in flower can hardly be said to be all that one could desire for house decoration. The new hybrid winter-flowering Begonias are, therefore, a most opportune as well as a valuable introduction, and none who know their value will care to be without them.

We lately paid a visit to the Feltham nurseries of Messrs. James Veitch and Sons, Limited, and there we found this new race of Begonias in splendid flower. Several houses are filled with them, and they were a blaze of colour. Visitors to the Drill Hall show of the Royal Horticultural Society have had plenty of opportunity of seeing these Begonias, for Messrs. Veitch have made some brilliant displays with them during the late autumn and winter months. To Mr. John Heal, who is a clever and practical hybridist, is due the inception of this race of Begonias, by crossing *B. socotrana* with the tuberous Begonias. *B. socotrana* is in itself a valuable and handsome winter-flowering Begonia, but its progeny has been much improved in the important considerations of floriferousness and compact habit.

Among the best of these Begonias are *Ensign*, which grows about 2 feet high, and produces branching heads of semi-double rosy carmine flowers upon stout footstalks. The flowers show well above the foliage, and render the plant one of striking appearance. *Begonia John Heal* is one of the most valuable, and for the reason that its blooms are extraordinarily persistent. It is of compact habit, growing some 9 inches to 12 inches high, with leafage much resembling that of *Begonia Gloire de Lorraine*, but much finer and larger flowers. Individual blooms of this variety have been known to remain upon the plant for nineteen days, so its value for decoration may be said to be unique. The flowers, which are of a bright glowing rose colour, do not drop off even when they are over; they just shrivel. This characteristic enables the plants to undergo a long journey without losing their blooms, which in itself is sufficiently rare among single-flowered plants to render them of more than ordinary value. *Begonia Mrs. Heal*, which grows about 15 inches high, has rich green leaves, and large, fully open bright red flowers. *Winter Cheer* is a variety that is well named, for its rich carmine semi-double flowers are well designed to make cheerful the greenhouse during winter. This is very vigorous, growing some 2 feet high, and producing strong, striking foliage. *Julius* may be considered to be one of the most distinct of this new race of winter-flowering Begonias; it usually reaches a height of some 18 inches and flowers profusely, the plants being almost covered with semi-double bright pink flowers, which have the merit of lasting a long time in beauty. *Agatha* has rather larger and brighter flowers, and is of more compact habit than *Begonia Gloire de Lorraine*. The flowers last well. *Agatha compacta* may be described as a very dwarf, compact *Begonia Gloire de Lorraine*. It makes charming little plants in quite small pots, and is wonderfully free-flowering. Success bears semi-double blooms of a glowing carmine colour, and has a yellow centre. *B. Ideala* flowers well in 3-inch pots; it resembles *B. Gloire de Lorraine*, but has bright carmine flowers. *B. Winter Perfection* is of stiff growth, has robust, handsome leaves, and bears rich rosy pink flowers, which have yellow centres. *B. Frœbeli incomparabilis* bears single blooms of a very bright red; it is to be recommended for the colour of the flowers alone.

In the houses at Feltham there are numerous other plants, often neglected or little grown, and in reintroducing and endeavouring to bring them into popular favour Messrs. Veitch are doing a good work. As an instance we may mention *Peristrophe speciosa*, an old plant that is very valuable during winter for the greenhouse. It is rarely grown except in botanic gardens, yet it is a plant of real value to the private gardener, and this is just one of many. We hope Messrs. Veitch will succeed in widely diffusing them, then perhaps we may see variety in the stoves and greenhouses in private gardens throughout the country where now too

often there is but monotony. *Primula obconica* stands sorely in need of improvement, particularly with regard to the colour of the flowers; there is little enough variety in the shades of colour now to be had, and they cannot be said to be of the most attractive. Messrs. Veitch hope soon to be able to effect an improvement in this respect, and it will be a most welcome one. *P. obconica* is a most useful plant, and when the colours of the flowers have been made more attractive it will be indispensable.

The Feltham Nurseries cover about sixty acres of land altogether, many of which are devoted to the culture of hardy fruit trees. Pot Vines, Figs, Peaches, Nectarines, Pears, Apples, Cherries, &c., are largely grown in pots under glass, and at the time of our visit many splendid plants were to be seen. The Figs in pots had made remarkable growth; from cuttings inserted early this year we were shown well-developed plants bearing fruits. The pot Vines, too, the Muscats especially, were remarkably good. One house is devoted to a collection of Oranges in pots, and in others are trained specimens of Pears, Apples, Peaches, Nectarines, &c. Some rider standard trees of Peaches, two and three years old, gave evidence of the very best culture; and of Cherry and Pear trees in pots we may say the same.

## PROPOSED GARDENERS' ASSOCIATION.

THE brief note published in last week's issue of THE GARDEN enabled readers to learn that there is a prospect that the hopes so many gardeners have formed, as to the creation of a national association devoted to their interests, are not unlikely to be realised. The chief difficulty which besets the promoters now is, not the lack of suggestions, practical or otherwise, but in their abundance on the one hand and need for putting them into a concrete form on the other. The recent meeting had the pleasure of hearing from Mr. W. H. Divers of Belvoir Gardens his reasons for desiring the formation of a national association of gardeners. These included a desire to relieve gardeners of the unpleasantness of being classed as ordinary domestics by Government, and thus enabling them to take similar status to that occupied by the higher staff of an estate. The gardening profession was far too overcrowded, with the result that not only were wages reduced but good men were shut out from places, although having by far the greatest experience, because cheap young men accepted positions at lower wages. One means of reducing the overcrowding was to require from young gardeners greatly advanced educational efforts, and a reduction of youths taken into bothies, so many of whom soon showed they had no gardening proclivities. He had not the least desire, a sentiment generally concurred in, to introduce into the proposed association any trade union element. He had always felt that nothing tended so strongly to promote comfort and happiness in a gardener as that he should possess fully his employer's confidence and esteem; he would like to see the association become the centre of all other gardeners' associations, and that it should also help to promote the interests of the gardening charities amongst the fraternity. Mr. J. McIndoe, V.M.H., much wished to see such an association formed. Whilst it was proposed to reduce both hands, of which in the south there seemed to be too many, in the north he had found it difficult to secure them, because wages generally in other vocations were so much better. The present overcrowding seemed to be in the older grade of gardeners, and if the trained bothy men were fewer that trouble would in time correct itself. Mr. G. Norman, V.M.H., thought they might look to the Royal Horticultural Society for some assistance in the direction mentioned. He thought the council could prepare a register of all gardeners seeking places, to which the employer might with confidence refer, and thus enable them to secure the services of the best men only. He regarded a testimonial from a head to a young gardener as a good certificate, because no one could have a better knowledge of the real merits or other-

wise of a youth than the head gardener had. Still there was a danger lest from kindly motives testimonials might be too liberally worded. He would like to see young men spending a year for training in forestry, in farming, in general estate work, &c., to fit them to become ultimately stewards and estate agents. Mr. J. Willard wished to see gardeners, and young ones especially, taking to the vocation seriously, making it the great aim of life, and seeking by personal effort to raise themselves and the status of the gardener also. Mr. J. Jaques wished to see some form of examination imposed on young men before being admitted to the position of foreman, which he thought should be conducted by the Royal Horticultural Society. Other speakers thought any such examination to be of a practical nature should be conducted by the gardeners' association itself. Mr. C. Fielder, Mr. W. Howe, Mr. Simpson of Croydon, and others spoke, including the chairman, Mr. Owen Thomas, V.M.H., who cordially thanked Mr. Diver for attending and giving the meeting an expression of his views. It was ultimately decided that a small committee be formed from the meeting to frame a scheme to submit to an adjourned meeting to be held on the afternoon of the second Drill Hall meeting in February. The committee comprised Mr. Owen Thomas, chairman; Mr. A. Dean, secretary; and Messrs. W. H. Divers, J. Jaques, McIndoe, Norman, C. Dixon, J. Willard, and J. Kelf, to any of whom gardeners wishing to make suggestions are invited to communicate early, as the committee will hold meetings in January for the purpose named.

## THE FRUIT GARDEN.

### EFFECT OF BASIC SLAG ON CURRANTS.

I HAVE this year had a most striking example of the effect of basic slag upon Red Currants, an account of which may not be uninteresting to readers of THE GARDEN. The trees are on a south-west wall some 5½ feet in height, and on the other side is a large Apple tree, so that it is generally a pretty dry position. In front of the Currant trees is a 4-foot border devoted to Carnations. Last autumn these were all taken up, and the border dug up for the first time for three years, at the same time receiving a good dressing of road sand, some rotted manure, and basic slag, at the rate of 5lb. to the 20 square yards, that is, 10cwt. per acre. The border was then replanted with Carnations. About the end of May all the Currant shoots above the wall were gradually pinched to two or three leaves, so as not to catch the wind, and at the same time the shoots from the base of the wall to the top were thinned by the same process to let the sun to the fruit, as well as to the next year's fruit-buds. At the final pruning in the autumn it was noticed that in the axil of the terminal leaf of each stopped shoot there were at least four or five buds, instead of the usual one only, while in the axils of the one or two leaves below, according to the extent to which the young shoot was pinched back, there were two or three buds. Most of these must be fruit-buds, probably all but one in each axil. An examination of similarly stopped Red Currant shoots on trees in other parts of the garden showed that there was only one bud in the axil of the terminal leaf, and in many cases the terminal bud had produced a secondary shoot.

It is a most striking proof of the effect of phosphate—basic slag being phosphate of lime—in inducing fruitfulness. Another noteworthy fact, which can scarcely be a mere coincidence, is afforded by a large Apple tree in my neighbour's garden, the roots of which I have often come across in my own. For quite twenty years that tree produced a large crop, averaging twenty bushels every alternate year, frost or no frost. Three years ago the vegetable quarters, where the roots of this tree are to be found, received a heavy

dressing of basic slag, which was repeated in a less degree last winter. The Apple tree under discussion has produced a good crop two years out of the last three, with a fair crop the intermediate year, and it is now well set with fruit-buds for next season. There can be little doubt that the tree rested alternate years while getting in touch with further supplies of plant food, and that the application of the basic slag brought the needed food to the roots, and so enabled it to bear every year.

A. PETTS.

### FRUIT GROWING IN QUEENSLAND.

THE Minister for Agriculture in Queensland, desirous of assisting fruit growers in his State by establishing new markets, has bought up the whole of the season's crop of Cape Gooseberries, a fruit which makes a delicious preserve, for pulping, and enquiries are being made in Great Britain as to the feasibility of establishing an export trade in this article on payable terms. Cape Gooseberry jam can be purchased in London, and as a table delicacy it would, were it generally known, be greatly appreciated. The Queensland Agricultural Department is also thinking of trying an experimental shipment of Pine-apples to London in order to test the transit question thoroughly. Pine-apples are produced in Queensland as freely as Apples are here. In the Brisbane district alone close on 200,000 dozen are grown yearly, and all over the State these delicious fruits are cultivated, and are an ordinary item of dietary. If shipped to this country it would be on a commercial basis, and the fruit would be sold cheaply. Bananas are produced in Queensland in enormous numbers; the average annual crop may be put at about 2,000,000 bunches, and taking, say, 120 "fingers" to a bunch, we get the estimated yield of single Bananas in Queensland for a year as 240,000,000! Bananas flourish everywhere on the coast lands, and many small settlers make a decent living by taking up virgin scrub at £1 an acre, and growing Bananas thereon after clearing. The Banana has the virtue of bearing all the year round in congenial conditions. Mangoes are grown in Queensland with such ease that in good seasons the local demand is unable to deal with the output; 1902 was a bad year for Mangoes, but in 1901 some 350,000 dozen were grown in the State. After some hesitation in taking to this fine fruit when it was introduced about twenty years ago, Queenslanders now regard it as a commonplace, and, raw and preserved, it is eaten all over the State. Oranges suffered from last year's drought, but their cultivation in normal seasons is an important section of the fruit department; about 20,000,000 Oranges were grown in 1901. There is a large export trade in all these fruits mentioned to the southern States of Australia, Queensland being the supplier of all the tropical and sub-tropical fruits to Australasia. The area of Queensland is so extensive (669,000 square miles) and the climate so varied that in one part or another every known fruit flourishes. Cocoanuts are grown on the islands which fringe the northern coasts in great numbers.—*North Queensland Herald.*

### RECENT PLANT PORTRAITS.

THE *Botanical Magazine* for January contains portraits of

*Cymbidium rhodochilum*.—Native of Madagascar. This is a handsome and still very rare Orchid, to which in this number no less than three plates are devoted. The double plate showing the heads of flowers life size, and the single plate the entire growing plant much reduced. It was introduced into cultivation by Mr. G. Warpur, and in its native country grows on masses of *Platyserium* on the branches of tall trees. Its flowers are green, with the two upper petals spotted with black, and a large red lip.

*Prostanthera denticulata*.—Native of Eastern Australia. This is a pretty shrubby labiate with rosy purple flowers very freely produced up the ends of all the shoots.

*Arethusa sinensis*.—Native of Western China. This is a pretty little terrestrial Orchid with bluish-

A RIVERSIDE GARDEN AT HAMMERSMITH, LONDON.

white tubular flowers, with deep rosy markings at their mouths.

*Passiflora vitifolia*.—Native of tropical America. This is also known under the synonyms of *P. sanguinea*, *P. punicea*, *P. servitensis*, *P. Buchanani*, and *Tacsonia Buchanani*. It is one of the most brilliant coloured and beautiful of the whole Passion Flower family, with large scarlet flowers. It is by no means a new plant, having been introduced more than fifty years ago. It requires a warm temperature, and grows at Kew in the Palm stove and tropical Lily house.

The *Revue Horticole* for the 1st inst. contains portraits of two fine new varieties of perpetual-blooming Pinks, named respectively Chatillon and Mme. Bixio. The January number of *Flora and Sylva* contains coloured plates of *Eurothera speciosa rosea*, a most beautiful and graceful plant, with clear rose-coloured flowers, and *Primula megasalfolia*, a pretty and free-blooming variety, but, unfortunately, not hardy, and requiring greenhouse culture.

W. E. GUMBLETON.

## OBITUARY.

### DEATH OF MR. JAMES SMITH, LATE OF HOPETOUN GARDENS.

BY the death of Mr. James Smith, late of Hopetoun House Gardens, on the 27th ult., Scotland has lost one of its best gardeners and a most estimable man. A native of Ayrshire, after filling several subordinate positions in various good gardens, Mr. Smith received an appointment in a Perthshire garden as head gardener, whence he went to Ingleston House, Ratho, in a similar position. Thence he was appointed gardener at Moredun House; later he was chosen to fill the still more important post of head gardener at Hopetoun House, Linlithgowshire, some sixteen years ago. There he remained, enjoying the confidence of his employers, the Marquis and Marchioness of Linlithgow, until the state of his health, which had practically laid him aside for a considerable time, necessitated his complete retirement in

November last. Through the thoughtfulness of his noble employers, Mr. Smith was enabled to retire to live at Hillview, Bonnyrigg, where it was hoped that he might be long spared to spend his declining years in peace and comfort. However, it was not to be, and the sciatic complaint, which had caused him so much suffering, eventually proved too much for his system, and he expired on the 27th ult., his funeral taking place at Abercorn Churchyard on the 30th ult., when his remains were accompanied to the grave by a number of sorrowing friends. Mr. Smith was a man of great ability as a gardener. He was specially interested in hardy fruits; but it is not too much to say that he was a good gardener all round, and the condition in which the extensive gardens of Hopetoun were kept showed his ability as a manager of men. He was highly esteemed in private life, and all who came in contact with him speak highly of his modesty and kindly disposition. None were more attached to him than his successor, Mr. T. Hay, who served under him as foreman for some years, and who had charge during the long illness of Mr. Smith prior to his retirement. His services were in much request as a judge and as a member of such bodies as the council of the Royal Caledonian Horticultural Society. Mr. Smith is survived by Mrs. Smith and several of a grown-up family, for all of whom deep sympathy is felt in their bereavement.

## A TOWN GARDEN.

If we could but be persuaded to take advantage of the opportunity at hand, instead of waiting for that which may never come, many gardens, amongst other matters, would fare better than they do. Town gardens are a proverbial trial to their owners, yet here and there, under no specially favourable circumstance, we meet with one which is entirely satisfying. The illustration is an eloquent example of simple arrangement, combined with loving care, and we should like to call attention to the great advantage of paved or tiled, rather than gravelled, pathways in such limited quarters. We were called in, not long ago, to prescribe for a small town garden whose unhealthy condition was an eye-sore to its owner.

The central plot had, in despair, been laid down with gravel not long before, but was already beginning to look sodden, and was blackened in patches with some fungoid growth. Many things had been tried in the borders under the surrounding walls; two Aucubas alone survived, but these were remarkably flourishing. It was evident, nevertheless, that something would grow, and here was the inspiring hint. Shade-loving shrubs—Hydrangeas, for example—and Ferns might yet retrieve the situation. Doctor's prescriptions are not always carried out; but flagged paths and a central border, with plants chosen according to aspect and not left entirely to the unaided effort of the jobbing gardener for after-cultivation, would go far to make the town garden something better than the dreary cats' paradise which too often it is at present.

## NOTES FROM THE MARKETS.

**CHRYSANTHEMUM A. J. BALFOUR.**—Though some growers condemn this variety I find others speak in its favour. It is certainly one of the best of its colour for pots. One grower has been bringing in some dwarf well-flowered plants in 4-inch pots; and as late as the 24th ult. it was in fine condition, the colour of the flowers being a very pretty shade of pink, perhaps a little deeper than the original type. The same grower also had a distinct sport from this variety, a pale cream, with just a slight shade of pink on the florets.

One grower from the south informs me that while he has not succeeded with Framfield Pink (Mme. Felix Perrin) he has found A. J. Balfour a most profitable variety; the blooms he submitted to me were bright in colour, and though not disbudded were of a useful size.

**Chrysanthemum W. H. Lincoln.**—We hear much of new and improved varieties, yet this still holds its own, and is one of the best yellows, especially for pots. Most of the market growers favour this, and good pot plants have been plentiful. For cut bloom, too, it is not to be despised, for it is of such good substance. There are few yellows which last so well, beside which it can always be depended upon to give good blooms.

**Princess Victoria.**—This is of a creamy shade when it first opens, but changes to pure white; it is one of the best for December. Several growers have been bringing in good blooms, it appears to be a general favourite with buyers; this was one of the best whites in the market on the 2nd inst., and it will evidently keep good for some time.

**Covent Garden Flower Market (January 2).**—The frosty weather has practically stopped trade in pot plants. Some growers were represented, but many of the stands were empty, and those who had ventured did not find much demand. Tulips and Hyacinths are now coming in, Tulips in all colours being very plentiful. Hyacinths are very good, but I have only seen them on one stand at present. Several growers are sending Azaleas, Genistas, Erica hyemalis, and E. gracilis are still coming in. Small Ferns now sell better, but larger sizes are not much wanted. Very high prices are asked for all good cut bloom. Some of the Chrysanthemums are now past their best, but there is plenty of good to be had at top prices. Lily of the Valley was plentiful. *Lilium lancifolium* and *longiflorum*, Callas, Azalea, Eucharis, and cut Poinsettias were equal to all demands. The Christmas trade finished up well, especially in cut bloom, which went up to high prices. Most flowering plants were pretty well cleared out, but there were a good many Ferns, Palms, and other foliage plants left over. There was a great demand for Holly and Mistletoe, and well-berried Holly made high prices. Christmas trees (Spruce Fir) did not clear out so well, and there were a good many left on the market.

# THE GARDEN

No. 1678.—VOL. LXV.]

[JANUARY 16, 1904.

## FLOWER-FORCING WITH ANÆSTHETICS.

**I**N the *Lancet* of the 9th inst. particulars are given of remarkable experiments with the use of anæsthetics upon plants. The object of the experiments is to prove that by the use of anæsthetics plants may be brought into flower at an abnormal season, and by their undiminished brightness add to the enjoyment of the indoor garden. The experiments have, therefore, a practical bearing upon commercial horticulture. It will be, therefore, interesting to our readers in general to reproduce the article referred to, as the experiments have been made with the greatest care to ensure practical results.

"The close similarity in composition and properties of animal and vegetable protoplasm is brought into strong relief by the extremely interesting and curious investigations that have been recently made on the action of the vapours of ether and chloroform in promoting the process of inflorescence in plants, or, in other words, in forcing them to flower at an earlier period than is natural to them. The production of early blooms in the Lilac, the Lily of the Valley, the Dentzia, and the Azalea is a large and important industry in the early spring, and for any grower to obtain well-developed flowers a week or two in advance of his brother horticulturists, especially if it can be accomplished at little cost, means large receipts, and, in addition, the satisfaction of successful rivalry. Many years ago Claude Bernard, desirous of recording the phenomena common to animal and plant life, submitted both to the action of anæsthetics. He placed a specimen of the sensitive plant under a bell glass with a small sponge dipped in ether and found that after the lapse of a few minutes the expanded leaves became insensible and ceased to close when touched.

"This experiment has been the parent of much research of late years, and the results obtained have been summed up by M. Emile Lemoine, a fellow of the Royal Horticultural Society, and have been published in the last number (October, 1903) of the journal of that society. The next step was taken by Dr. W. Johannsen of Copenhagen, who, noticing that many plants push forth their buds after a period of repose such as occurs during the winter months, or even in unfavourable seasons during the summer, conceived the idea that by inducing such a condition of rest by means of

anæsthetics the plants would be, as it were, renovated and stimulated, and rendered capable of developing their buds with greater vigour. Acting on this principle, Dr. Johannsen was able to show at a meeting of the Copenhagen Academy of Sciences Lilac blossoms forced by etherisation.

"The value of the proceeding was quickly recognised by horticulturists in Germany, France, and England, and these experimenters all proved in accord in regard to the remarkable power that the vapours of ether and chloroform have in promoting the formation of the inflorescence of plants. Lilacs, and especially the variety named Charles X., which is notably a difficult one to force, Lilies of the Valley, Azaleas, and Deutzias were subjected to the vapour of ether, and stimulant effects on the production not only of flowers, but of leaf-buds and leaves, were observed. M. Leblanc reported to the Société Centrale d'Horticulture de Nancy that his experiments with chloroform had been quite successful. On February 19 last he chloroformed some plants of *Azalea mollis*, giving them about half the quantity he would have used had it been ether, and exposing them to the action of the vapour for about forty-eight hours. They were at once removed to a greenhouse at a temperature of 65° Fahr. From March 5 the flowers began to expand a little, and attained about to their full dimensions on the 8th, whereas plants grown for comparison were not expanded until March 21. The chambers in which the vapours are set free should be of large size, and, to prevent their escape, should be absolutely airtight; and all manipulation must be executed in the daytime, since the approximation of a light, if air has gained access to the interior, is liable to be followed by violent explosion, which may occasion great destruction of property and possibly loss of life. The quantity of ether employed to air was about 30 or 40 grammes of pure sulphuric ether boiling at 95° Fahr. to 100 cubic litres of air, and the duration of exposure one or sometimes two periods of forty-eight hours. The economy of fuel effected by this method of forcing, which can be done at either a high or a low temperature, is considerable, and covers the cost of etherification."

It will be interesting to see whether this use of anæsthetics will become general. We doubt it, but in these days the desire to possess flowers out of season is increasing, and we confess that Lilacs, Azaleas, and Lilies of the Valley are enjoyable when winter is still with us.

## COLOUR SCHEMES IN THE MIXED BORDER.

It is a great pleasure to me to find that my article of the 28th November last has called forth so many interesting and useful contributions on this subject, and I am truly grateful to "G. J.," Mr. W. T. Hindmarsh, "Evelyn," Mrs. Mary Buxton, and Mr. S. Arnott for their kind suggestions in recent numbers of *THE GARDEN*. Aided by these and by much valuable advice received in the course of conversation with gardening neighbours, to say nothing of my own study of various books and catalogues, I have now compiled quite a long list of "desiderata," including many blue, or nearly blue, shrubs and plants, and I begin to wish I had an empty border once more to begin work upon. I fully expect I shall be marching and countermarching my poor soldiers, especially the blue regiment, about the border for several years to come—a state of things which may end in the "survival of the fittest" alone! It is, perhaps, well I did not start with too large a number of "recruits" last spring. To arrange that blue corner artistically and satisfactorily seems to me almost hopeless, for though there are a fair number of perennials and annuals that are undeniably blue, the shrubs available are nearly all grey-blue, or of some shade of purple, violet, or mauve. If only such a good coloured shrub as *Ceanothus Indigo* were quite reliable I believe it would be the very thing, but I fear that, at any rate till the Beech hedge has grown a lot, the situation is too exposed for it.

I wonder if any reader of *THE GARDEN* has tried the varieties of *Amorpha fruticosa*, the *Amsonias*, *Rhazya orientalis*, or *Teucrium fruticosum* in an open border. I should be very grateful for any information as to the proper soil for these shrubs, their hardiness, &c. Another blue-flowered shrub I should like to grow is the dwarf *Erinacea pungenis*, figured in *THE GARDEN* of the 5th ult. as growing in Canon Ellacombe's garden at Bitton, but I have never come across the name in any catalogue. It must be a most desirable thing, and, if so common in Spain, ought to be procurable. Its particular habitat in Spain does not appear to be recorded. I went through a good many miles of exceedingly spiky and prickly shrubs within twenty miles of Gibraltar during the four years I rode about the country and hunted with the Calpé hounds, but I cannot recollect having seen a blue flower on any of these shrubs. In Nicholson's "Dictionary of Gardening" it is described (under its old name *Anthyllis erinacea*) as having bluish-purple flowers, and as being "hardy in a dry, sunny position on the rockery," so I fear it will hardly do for my border. So much for the blue shrubs. Perennials and annuals are far easier to deal with, and I do not foresee any great difficulty in filling up the front portions of the section, though it may be a long time before the various shades of colour are properly

arranged. Things I intend to try are *Geranium grandiflorum*, *Mulgediums*, *Dracocephalums*, *Anchusa italica* (the Dropmore variety if possible), *Aconitums*, *Mertensias*, *Myosotis*, and perhaps *Polemonium confertum*, with a few good annuals such as *Phacelia*. I fear *Myositidium nobile* is out of the question. A neighbour who grows it well, with the aid of a frame-light in winter, tells me it will not stand more than 6° of frost. I lost the first plant he kindly gave me, though it was protected with ashes, &c., from frost, and I now always take up a second from the same friendly source and winter it under glass. This want of hardiness is most unfortunate, for it is one of the most beautiful plants in cultivation.

I have not grown *Iris cristata* until the present time, and do not know how it is going to turn out, but it would certainly make a most desirable edging for the blue section, as suggested by Mr. Arnott.

I have quite come round to "G. J.'s" ideas as to the employment of both bulbs and annuals in the colour scheme. There will eventually be no bulbs save Lilies, and I hope to make successful use of suitable annuals in future in all the sections. Annuals are worth the slight amount of trouble necessary for their proper cultivation, but bulbs are rather a nuisance, as either their position must be denoted by unsightly labels, or they run the risk of being chopped up with the spade or uprooted by the fork when a new plant is being put in or an old one moved.

As regards the "superlatively lovely" edging to the cross-path in front of the *Yuccas*, alluded to in my former article, I may mention that the *Yuccas* are set a good way back in the border, with dwarf *Tritomas* in front of them, so I think Mr. Arnott's white Pinks or my own *Daphne Cneorum* would not spoil the general effect, but rather improve it.

To conclude with a few words on another subject connected with the planting of dwarf shrubs, perennials, &c., generally.

When sheltering some of my newly-planted shrubs, such as *Ceanothus*, *Berberis nepalensis*, &c., the other day with evergreen boughs, it suddenly occurred to me to make use of a number of nice bushy young *Yews*, about 6 feet high, standing idle in a nursery bed. I dug these up with good roots, and carefully planted them among the more delicate shrubs so as to form an effective screen against the north and east winds. They take up very little room, and I propose to keep moving them about from one spot to another every autumn until their services are no longer required. With care they ought to keep growing a bit; at any rate, they should last several years. A few small superfluous Laurels and Box trees have also been enlisted on the nursing staff. I cannot tell if this idea is new or not, but it may be of use to some who are or have been planting tender things in open borders.

So far we have had a mild winter, but in this climate of "samples" we never know what to expect—at any rate, before the end of May.  
Yalding, Kent. S. G. R.

## NOTES OF THE WEEK.

### FORTHCOMING EVENTS.

January 16.—Société Française d'Horticulture de Londres Annual Dinner at the Imperial Restaurant, Strand.

January 21.—Gardeners' Royal Benevolent Institution Annual General Meeting at the Covent Garden Hotel, 3 p.m.; Annual Supper, Covent Garden Hotel, Mr. Leonard Sutton in the chair, 6 p.m.

**The Royal Gardeners' Orphan Fund.**—Sir Trevor Lawrence, Bart., K.C.V.O., President of the Royal Horticultural Society, has kindly consented to preside at the next annual festival of this fund, which will take place at the Hotel Cecil on Tuesday, May 17.

**The Gardeners' Royal Benevolent Institution.**—I am asking for a little space in THE GARDEN to make an appeal to its readers on behalf of this excellent and most deserving charity. My aim is to arouse on its behalf the active sympathies of a larger number of persons who take a great interest in their gardens and in the work of the gardener. On Thursday, the 21st inst., the sixty-fifth annual meeting of the institution is to take place in the Covent Garden Hotel at 3 p.m., at which the treasurer, Mr. Harry J. Veitch, will preside. On that occasion twelve pensioners are to be elected on the fund. The distressing part of the proceeding is that there are fifty-three applicants. Of these applicants two are eighty years of age, twenty-four are seventy years of age and upwards, while twenty-five are sixty years of age and upwards; all incapable of work, depending upon scanty savings, the assistance of relatives, or the charity of friends. Every application is more or less a touching tale of woe; some must be in dire poverty. Two applicants—men under ordinary circumstances in the prime of life, one fifty-one years of age, the other fifty-three—are incurably paralysed and altogether incapacitated. Only think that of these fifty-three applicants forty-one must be unsuccessful! Think of the misery of unrealised hopes on the part of those who fail to be elected! The annual subscription is one guinea, but in every locality there is some gardener who, interested in the institution, would gladly constitute himself a centre to receive the smallest contributions and so make up a few guineas, by means of which votes could be secured at future elections. When addressing the members of the Ealing Gardeners' Society a few evenings ago I appealed to the members to subscribe each one penny per week, which could be collected by the secretary, and when the sum of a guinea was reached one of their number might be nominated as a guinea subscriber and have the privilege of giving five votes at the next election. There are many gardeners' societies about the country, and could they be induced to take an interest in the institution in the way I have mentioned, I am sure a considerable amount of most acceptable support would be forthcoming. The secretary of the institution is Mr. George J. Ingram, 175, Victoria Street, London, S.W.—R. DEAN.

**The proposed gardeners' association.**—What is wanted are ready offers of practical assistance, whereas the chief offers to hand have been in the form of advice, very much of which is amusing; very little is of practical value. The report of the first meeting of gardeners held to consider the subject you kindly published at page 31, and it includes mention of a small committee that was formed to give the subject closer consideration and to report on the result. It may interest readers of THE GARDEN who have been concerned with the proposals to learn that this small committee has met and thoroughly threshed out the matter, and the recommendations made I have been requested to embody in the form of a report to be read to the larger meeting, which will be held at the Hotel Windsor, by kind permission, on the afternoon of February 23, at 2 p.m. I hope it will be possible to furnish a copy of that report to THE GARDEN, so that all readers may learn of the decision at which the committee have arrived. May I suggest that if anyone has a really earnest desire to see a National Gardeners' Association established, rather than writing to the papers and indulging in very unpractical criticisms they should attend the meeting in question, which will be an entirely open one, and there offer suggestions that would be helpful and practical. Unless there be manifested a much stronger desire for such an association than is now shown, and the reasons for its existence be made far more clear and imperative, I gravely doubt whether anyone's desires are likely to be gratified. With such a body entire union is an essential element to success.—A. D.

**Indian Agricultural College.**—The plans for Government buildings at Pusa, where the Phipps Laboratory and Agricultural College are to be created and an experimental farm started, are now nearly ready. The laboratory, for the establishment of which Mr. Phipps gives £20,000, will be perfectly equipped with the latest modern appliances. Pusa will become a centre of agricultural research, experiment, and instruction, and a great future of usefulness lies before it.

**Royal Botanic Society: Preliminary arrangements for 1904.**—Exhibitions of plants and flowers will be held on Wednesdays, March 16, April 13, May 11, June 8, July 6, October 12, and November 9. Exhibition of *Rhododendrons*.—By Messrs. Waterer, Bagshot, Surrey, daily during June. Admission: Wednesdays, 2s. 6d.; Mondays and Saturdays, Is., or by Fellows' orders. Exhibition of hardy flowers.—By Messrs. Barr and Sons, Covent Garden, during June. Admission: Wednesdays, 2s. 6d.; Mondays and Saturdays, Is., or by Fellows' orders. Musical promenades.—Every Wednesday afternoon from June 15 to July 27 inclusive. The Guards' band from 3.30 to 6 o'clock. Admission by Fellows' orders. Illuminated evening fêtes.—Wednesday evenings from June 15 to July 27. The Guards' band from 8 to 11 p.m. Admission tickets, 2s. 6d. each, or Fellows' packets of ten, 10s. Botanical lectures.—Friday afternoons at 4 o'clock, May, June, and July. Admission by Fellows' orders. General Meetings.—For election of new Fellows, scientific papers, &c., fourth Friday in the month at 4.30 p.m.; anniversary meeting, Wednesday, August 10, at 1 p.m.

**Buddleia asiatica.**—In your issue of the 9th inst. (page vii.) there is a note sent by my friend Mr. W. E. Gumbleton about *Buddleia asiatica*, and in it occur some errors that ought to be corrected. He says that I submitted some flowers of this plant for examination to the botanical authorities of the *Muséum d'Histoire Naturelle*, Paris. This is incorrect. I said in the *Revue Horticole* (1901, page 37) that I had been unable to identify the plant with any one of the 150 described species of the genus *Buddleia*, and therefore I provisionally named the plant *B. Columbia*, adding "unless someone could find it described elsewhere." As soon as I found that my plant was the *Buddleia asiatica* of Loureiro I restored the true name in the said journal (1903 page 562). This species seems difficult to identify, probably owing to its numerous synonyms. These synonyms I give in alphabetical order: *Buddleia acuminatissima*, Blume; *B. Columbia*, And.; *B. densiflora*, Blume; *B. discolor*, Roth; *B. interrupta*, Buch.—Ham; *B. lanceolata*, Heyne; *B. Neemda*, Buch.—Ham; *B. salicina*, Lam.; *B. serrulata*, Roth; *B. subserrata*, Don; *B. sundaica*, Blume, as far as I know, up to the present date.—ED. ANDRÉ, Editor *Revue Horticole*, Paris.

**What France exports to England.** According to the statistics for 1902, France exported to England 33,000,000 of Strawberries, Cherries, Plums, Pears, Gooseberries, Almonds, Apricots, Peaches, Grapes, Nuts (fresh), Chestnuts, and Walnuts; 28,000,000 of vegetables (fresh, salted, or preserved), of which more than 15,000,000 were Potatoes; 8,000,000 of flowers; and 2,000,000 of greenhouse plants, bulbs, and flower seeds.

**British exhibits at the St. Louis Exhibition.**—The extensive preparations for the reception of horticultural exhibits have progressed rapidly. The first arrivals from England have just been announced, and among them are bulbs and hardy plants from Messrs. Sutton and Sons, Reading; James Carter and Co., High Holborn; Phlox from Mr. John Forbes, Hawick; and Dahlias from Messrs. J. Cheal and Sons, Crawley. Other houses, for instance, Messrs. Kelway and Son and Messrs. Cannell and Sons, have already arranged their exhibits. *Le Jardin* says that Mr. W. Goldring, who has charge of the general arrangements, has a representative at St. Louis, who receives the horticultural exhibits on their arrival, superintends their arrangement, and looks after their welfare.

**Akebia quinata fruiting.**—In THE GARDEN, November 7, Mr. S. Arnott announced the fruiting of *Akebia lobata* in England at Newstead Abbey. This ornamental climber fruited also last summer in a garden at Haarlem. It stands at the north-east side of a closed verandah in a sandy soil.—LEONARD A. SPRENGER, *Haarlem*.

**Moschosma riparium.**—This South African Labiate deserves to be grown more largely than it is at the present time, as it is an extremely useful plant for the cool greenhouse during the dull winter months. The creamy white flowers, with dark anthers, are produced in long, branched, terminal cymes, and will last in flower in good condition for three weeks or more if grown in a cool house. Although this plant has been in cultivation for some few years, it is only recently that really well-grown examples have been seen, the plant being well shown by Messrs. James Veitch and Sons, also by Messrs. H. Cannell and Sons at a recent meeting of the Royal Horticultural Society, when an award of merit was very deservedly gained. The chief factor in the successful cultivation of this plant is to give it a light, airy position in a cool, well ventilated house, and not over hot, trusting rather to frequent applications of liquid manure water when the pots are well filled with roots. Strong and mature growths are then produced, which flower far more satisfactorily than when the plants are grown in a warmer temperature and the wood is not properly ripened.—W. HALES, *Physic Garden, Chelsea*.

**Cymbidium tracyanum, Bradshaw's variety.**—In a recent issue of THE GARDEN mention is made of Mr. Briggs Bury's variety of this *Cymbidium* as being "the darkest form in existence." But the two flowers now before the writer, forwarded by Mr. J. Bradshaw of The Grange, Southgate, prove that, if not quite so large in size, they are at least as dark in colour, with a decidedly larger and more showy labellum. This huge tongue-like petal, with its rich orange-crimson coloured spots, is a conspicuous contrast to the dark chocolate-red and yellow-tinged sepals and petals, and a large inflorescence of flowers would be a magnificent object. Mr. Bradshaw may be congratulated on having one of the darkest and finest of all known varieties of *Cymbidium tracyanum*.—JOSEPH GODSEFF.

**Schubertia grandiflora.**—This fine Brazilian climber deserves all that has been said in its favour (THE GARDEN, January 2, page 3), but it has one fatal drawback, which is seldom or never mentioned when reference is made to it, namely, the peculiarly strong and obnoxious odour of its stems and leaves. This may not be very noticeable, it is true, except in handling the plant or flowers, or in accidentally brushing past it; but it is sufficiently unpleasant to make it quite intolerable to many people. This is probably the reason why so lovely a plant has not become more popular, for there is no question as to its beauty, nor of the delicious fragrance of its flowers, apart from the stems and foliage. There is no difficulty, moreover, in its cultivation. The name *Schubertia*, it may be noted, has given place to *Arauja*, or *Araujia*, as it may be found spelt in both ways in the "Kew Hand Lists."—K. L. D.

**Tillandsia carinata.**—Bromeliads are not favourites in this country, yet many of them are, from a foliage point of view, very handsome, while the flowers are, in numerous instances, remarkable for their bright hues and distinct appearance. The rich purple *Tillandsia Lindenii*, before now noted in THE GARDEN, is still in flower, and to that an addition comes in the species at the head of this note—*T. carinata*. This is a pretty, small growing kind, the entire plant—flower-spike and all—reaching a height only of about a foot. The light green recurving leaves are arranged in a vase-like manner, and at all seasons are very pleasing; but of course the plants are far more

attractive when they are in bloom. The flower-stem, which well overtops the foliage, is furnished on its upper part with two opposite rows of comparatively large boat-shaped bracts, deep bright crimson, shaded with purple at the base, which gradually merges into the orange of the upper part. The flowers themselves are yellow, but they do not protrude far beyond the bracts, and, in addition, they do not last long, therefore these bracts must be regarded as the showiest portion of the inflorescence. It is of easy culture if potted in fibrous peat and sand, given good drainage, and ample water during the growing season. Though the above is now regarded as the correct name this plant was at one time known as *Vriesia brachystachys*, and as such is still more generally met with in gardens and nurseries.—H. P.

**Rainfall in a Hampshire district.** The rainfall for 1903 has been so excessively high in this district that I am forwarding the grand total for the year, which I hope you may find space

for 10:35 inches of rain. On two occasions during this month, viz., the 12th and 27th, 1.89 inches and 1.28 inches fell respectively during the twenty-four hours.—G. ELLWOOD, *Swanmore Gardens, Bishop's Waltham*.

**"How Dundee could be beautified."**—Under the above title the *Dundee People's Journal* gives prominence to a most interesting article by "An Expert," containing a number of practical suggestions for the beautifying of Dundee by means of the planting of trees, the provision of window boxes, and the improvement of the smaller open spaces. The writer gives a rather gloomy picture of Dundee as it is, and those who have visited this busy manufacturing city will not be disposed to question his opinion. As he says, it is admitted that Dundee cannot be transformed into a garden city, but a great deal can be done to improve it, and it is to be hoped that the suggestions of "An Expert" will receive the support of the authorities, and that the coming summer will see an improvement in the look of the bustling city. A brief quotation from the conclusion of the article will show the spirit in which it is written, and will meet with the approbation of the many readers of THE GARDEN who favour the garden city schemes as well as the improvement of existing cities on the same lines. "An Expert" thus concludes: "It is well known that there are in and around Dundee many odd corners, sombre, obscure, and unlovely, to which trees and flowers would act as harbingers of better things, better surroundings, and, above all, possibly better homes. There is a good time coming; though coming slowly, it is coming surely, and an evidence of this is shown in the earnest progressive spirit of the time." The same article also speaks in appreciative terms of the improvements at present being made at Seabraes under the burgh engineer and the superintendent of parks. It is a sign that the suggestions of the writer of the article referred to will be well received by the city authorities.

**Winter-flowering Begonias.**

The far-reaching effects of the introduction of three or four species of tuberous-rooted *Begonias* from the Andean region of South America, which took place in the sixties, has had a parallel in the case of *Begonia socotrana*, which was discovered and brought to this country in 1880. There is, however, this important difference, that whereas the South American kinds have given us a large and valuable race of summer-flowering plants, *B. socotrana* has played a great part in the production of an entirely new section, whose great value consists in the fact that they are at their best during the dull days of winter. When *B. socotrana* was first introduced it was from its distinct character, showy blossoms, and the season at which they were borne, regarded as likely to prove of great value to the hybridist, a prediction now fully borne out, though it was necessary to wait three or four years for the first start. This was the variety John Heal, obtained by fertilising the flowers of *B. socotrana* with the pollen of a tuberous-rooted variety—Viscountess Doneraile. Since this success there has been no turning back, and the groups of this section of *Begonia* which Messrs. Veitch put up regularly at the Drill Hall during the late autumn and early winter, are the admiration of everyone, and the cause of their cultivation being taken up by gardeners in general. Their popularity can be readily understood, as they are not at all difficult to cultivate, and the flowers are particularly bright and cheerful. The varieties enumerated by Messrs. Veitch are Ensign, Ideala, John Heal, Julius, Mrs. Heal, Winter Cheer, and Winter Perfection. They are all good, but for a display perhaps Winter Cheer is the equal of any. The above, however, do not occupy the first place among *socotrana* hybrids, that being filled by the now universally-grown *Gloire de Lorraine*, obtained

SHOOT OF MOSCHOSMA RIPARIUM.

for in your valuable paper. The time of observation here is 9 a.m. daily for the twenty-four hours preceding. The diameter of gauge is 8 inches, and 390 feet above sea level:—

Month.	Total depth in inches.	Greatest fall in 24 hours.		No. of days on which rain fell.
		Depth.	Date.	
January ..	2.48 ..	.63 ..	4th ..	17
February ..	1.68 ..	.53 ..	27th ..	11
March ..	3.39 ..	.68 ..	17th ..	20
April ..	2.81 ..	.94 ..	28th ..	10
May ..	3.55 ..	1.15 ..	2nd ..	13
June ..	2.64 ..	.59 ..	10th ..	9
July ..	3.52 ..	1.04 ..	26th ..	13
August ..	3.79 ..	.74 ..	12th ..	16
September ..	2.41 ..	.60 ..	5th ..	13
October ..	10.35 ..	1.89 ..	12th ..	28
November ..	2.57 ..	.83 ..	28th ..	15
December ..	3.92 ..	.82 ..	10th ..	14
Total ..	43.11 ..			179

It will be observed in the above table that rain fell on 179 days. The month of October was responsible for twenty-eight wet days, and registering

by M. Lemoine of Nancy by the intercrossing of *B. socotrana* and the South African *B. Dregei*. This variety was distributed in 1893, but it was two or three years before its merits were generally recognised, since which time it is grown to such an extent as to suffer by repetition. There are some forms of this, and of them Turnford Hall, with blush-coloured blossoms, is about the best. An interesting member of this group (*Agatha*) has been raised by Messrs. Veitch by employing instead of *B. Dregei* the creamy white *Moonlight*, a hybrid raised many years since by the late Colonel Trevor Clarke, but which had almost dropped out of cultivation till rescued some three or four years ago. Colonel Clarke will be remembered as the raiser of a summer-flowering variety (*Weltoniensis*) which a quarter of a century ago was largely grown and a popular market plant.—H. P.

## TREES AND SHRUBS.

### COLLETIA CRUCIATA.

**P**ERHAPS better known as *Colletia bictoniensis* is this curious shrub. Just now it is in bloom, and although the flowers are small they are very interesting, for one is somewhat surprised to find that such a forbidding plant as the prickly *Colletia* produces flowers at all. In this case they are small, pendulous, and very like miniature *Lily-of-the-Valley* bells. When taken into a warm room they emit a pleasing fragrance somewhat suggestive of *Aniseed*. True leaves are very few and usually short lived; they are simple, opposite, entire, very small, and deciduous. The shrub, which rarely grows more than 4 feet high, is composed of branches of alternately-opposite flattened spines, which are sharp pointed, the whole forming an impenetrable mass.

Cuttings of half-ripened shoots will root readily in sandy soil if placed under a hand-light in a cool house. The plants should be well rooted before being placed in their permanent position, which should be well sheltered and not too near a path. A well-drained, light soil suits it best. Although considered to be only half-hardy, established specimens will stand 16° or 18° Fahr. of frost with a light covering over the roots. During a mild autumn it frequently makes a short second growth; this, of course, suffers from frost, and should be removed in the spring.

North Cornwall.

A. C. BARTLETT.

### AROMATIC SHRUBS.

(Continued from page 12.)

THE Thyme of the Riviera is not the small creeping Thyme of our downs, but is a small shrub of great beauty, looking at a short distance very like a dwarf *Heath*. It is strictly a Mediterranean plant, but can easily be grown anywhere, and has long had a place in English kitchen gardens. If we could grow it as it grows in the Riviera it would deserve a better place in our gardens. The *Pistacia*, of which there are two kinds, is abundant in the Cap Martin woods, and is a very ornamental shrub, with bright leaves and curious winged petioles, but the scent of the leaves and wood is not pleasant. Though strictly a Mediterranean shrub, it can be grown in England; but though I have had it in my garden for many years I never saw a flower on it. It has in France a great reputation as the best firewood, burning very brightly to the last ash. It is closely allied to the *Sumach*.

It is time, however, to come to the aromatic character of these shrubs. They have in their flowers and on their leaves or bark very distinct odours. The flowers are sweet scented to attract the necessary insects. The scent of the leaves and bark are for the purposes of protection. To us the scent may be pleasant, but we know very little as to what is agreeable or otherwise to sheep, goats, or other browsing animals; we only know that certain plants are not eaten by them, and it is fair to suppose that they are let alone because they are unpleasant or not good for their food. What is pleasant to us may be very unpleasant to them;

we like the Thyme, but the Riviera Thyme is untouched by sheep and goats; and though the flowers of our little Thyme may be eaten by sheep, they do not generally touch the leaves or branches; if they did we should see the pretty carpets torn and pulled out of the ground, and I do not remember to have ever seen that. When we once realise that even the minutest part of every plant has its work to do in the perfecting of the flower we have a clue to many of the mysteries of plant life. The work done by strong-scented leaves and bark is protection, and well they do their work. In all of them the strong scent resides in glands, which are very visible in the leaves of the Myrtle, and still more so in the leaves and in the bark of the *Eucalyptus*, which is of the Myrtle family, and is now becoming quite naturalised in the Riviera. These glands do not give out their scent unless they are broken, and they are easily broken by wind, rain, or any passing man or beast. You may walk through the woods of Cap Martin and detect no aromatic scent at all, but gather any of those I have named and it is at once revealed; if you even touch the Rue the scent will remain on your hands or gloves for hours.

But Nature has many other ways of protecting flowers than by scents or flavours that are unpleasant to browsing animals, and we may say that every plant is provided with its own separate protection, each protection being suited to the special enemy. The woods of Cap Martin give good examples. The grand shrubby *Euphorbias*, which are such an ornament on the rocks near the sea, are well protected by the nasty milky juice which is so abundant in them, and there are three plants worth mentioning, very ornamental and protected by their thorns—the *Asparagus acutifolius*, *Smilax aspera*, and *Calycotome spinosa*. The *Asparagus* is quite hardy in England, and evergreen; the *Smilax* is the same, but the *Calycotome*, which is the handsomest, is rather tender. All three are well protected by thorns, especially the *Calycotome*, whose beautiful Broom-like flowers are protected by thorns which would defy almost any animal; and all three not only protect themselves, but give protection to other plants. I suppose that throughout the vegetable kingdom thorns are the chief protectors, and it is worth noting that Nature does not waste her means of protection; she may protect by bitter leaves, or by nasty juices, or by thorns, but does not use them wastefully; if she protects by scents she does not by thorns. I only can recollect one instance to the contrary. Our own Sweet Briar has both scented leaves and thorns, and I know of no other plant with such a double protection to the flowers; and perhaps it is not a double protection, it is quite possible that the scented leaves were even an attraction, and so the further protection of thorns was necessary. This double provision for the Sweet Briar did not escape Shakespeare:

"Briars shall have leaves as well as thorns,  
And be as sweet as sharp,"

i.e., sweet leaves and sharp thorns. But how great a protection thorns are may be seen in the *Cactuses*, which grow in dry places, and each *Cactus* carries its own ample reservoir of water; and if it were not for the formidable array of thorns these reservoirs would soon be broken into and emptied. The most beautiful instance of thorn protection, and one that fully proves the intention of thorns, is to be seen in the great American *Aloe* (*Agave americana*), now fully naturalised through the Riviera. In the whole vegetable world no plant has more rigid leaves, each leaf being made more rigid by being very much thickened at the base, and ending with a long and hard thorn. Such leaves seem almost immovable, but there comes a time in the life of the plant when these stiff ungainly leaves move themselves. That time comes when the plant is preparing to flower, which does not occur till it is from ten to twenty years old. Then these stiff leaves raise themselves and bend over the coming flower-shoot, and form an almost impenetrable fence, but one that the flower can get through and rise sometimes to a height of 20 feet or 30 feet. The young flower is probably very sweet, for if destroyed there comes in its place a plentiful supply

of the sweet intoxicating pulque; but if allowed to grow the matter which would form the pulque is drawn up the long flower-stem, and the flower is fully formed and the seeds are ripened; and then the thorny leaves have done their work, and they all die.

My paper is already too long, or I should like to have touched on many more points of interest belonging to the Riviera plants.

H. N. E., in *The Pilot*.

## THE FLOWER GARDEN.

### THE PINK.

**H**ALF a century ago the garden Pink was one of the most popular flowers in the florist's calendar. In my early gardening days I was acquainted with many Pink fanciers. The two most prominent were the late Mr. Charles Turner of Slough and the late Mr. John Keynes of Salisbury. Mr. Keynes was better known as a *Dahlia* grower, in the days when single-flowered *Dahlias*, if they happened to appear amongst the seedlings, were thrown on the rubbish heap, and when the *Cactus* and *Pompon Dahlias* were unknown to cultivation. The self-coloured and the fancy *Dahlias* were greatly improved by Mr. Turner and Mr. Keynes, not to mention others. I remember Mr. Keynes stating at one of our meetings that he had known six Pink shows to be held in Salisbury in one year. There were many raisers of Pinks in those days, and nothing was thought of any value that was not perfectly laced. When Thomas Hogg of Paddington published his sixth edition of "Florists' Flowers" in 1839, he wrote a long article on the culture of the Pink. He was a celebrated florist in his time, but he states "that I am neither gardener nor florist professionally, but that I commenced the cultivation of flowers in the first instance with a view to amuse a depressed state of mind, and reinvigorate a still more sickly state of body." He was entirely successful, as the fine flowers he exhibited and the excellent papers he wrote on his favourite flowers abundantly testify. Hogg gives a list of 154 varieties, after discarding the names of many of the old ones. These 154 varieties have the raisers names attached, and these number ninety-five. Think of it!—ninety-five florists, all in friendly rivalry in endeavouring to improve the garden Pink, and all working to obtain one distinct form of it. This precious object had a pure white ground, a pink, red, or dark red centre, with a lacing near the margin of each petal of a similar colour. The old florists were most exacting in their tastes, and rigidly excluded all others. I raise a few hundreds of seedlings annually, and there may be three or four, or perhaps, if I am in luck, half-a-dozen of these laced varieties; amongst the remaining hundreds there may be a score or more that have reverted to the single form, many more semi-double, and a great many very beautiful indeed as garden flowers. The seedlings flower so profusely, I have had 300 or more blooms on a single plant.

To get good strong plants sow the seed in February or early in March. The seedlings appear in a week or so (they are, of course, sown in heat), and should be pricked out in boxes, and gradually inured to the open air to be planted out a foot apart in beds of rich soil about the last week in May or early in June. They are not expected to flower until the next year after sowing the seed, and a selection can be made from them to be propa-

gated and flowered the following season. There are no Pink shows now, nor a special National Pink Society. In 1839 there were ninety-five raisers of Pinks known to us; there were six shows of Pinks in one town in one year. Friends, brothers, florists, what a fall is here! A Daffodil Society; even the Sweet Pea has a society all to itself. The Auricula, the Rose, the Carnation, the Dahlia, and the Chrysanthemum hold high festival through their special societies, but there seems no room for the Pink. I do not regret this, for it would be dragged from its quiet nook, where it is tended by loving hands. Choice specimens are culled and placed in glass vases or delicate china ones, and the perfume is always delicious. Carnations are sometimes sadly lacking in perfume, but never a Pink. For perfume the Carnation is not in it as compared to the Pink; besides, the latter is a more easily grown plant, and prefers out of doors culture to any treatment under glass. I have grown the Pink since I could cultivate anything, and would feel a great want if I had not a bed of Pinks to flower every year. No glass houses, frames, or even hand-lights are necessary. They can be propagated either by pipings or layers, and this can be done a month earlier than the Carnations can be layered.

I believe, upon the whole, it is better to propagate the stock of plants from layers. If from slips or "pipings," these can be taken off in June and they will form roots in a shady place out of doors, or, better, in a hand-light. They may be planted out in beds of rich, deep soil in September or October; if in the flowering bed they may be a foot apart, but it is better to plant the layers or pipings out about 4 inches asunder until they have formed plenty of roots and have gathered strength. Such plants may be put out in the open garden where they are to flower in October. The treatment they require is much the same as that for Carnations, except that they may be planted much closer together. Some attention is required during the winter; the ground must be kept free from weeds, and the surface may be lightly stirred occasionally. If rabbits or hares get into the garden almost the first plants they will visit are the Pinks and Carnations. Slugs and the leather-coated grub will also eat the leaves and sadly disfigure the plants. Wireworms are also destructive. The leather-coated grub also burrows in the soil, but, unlike the wireworm, which eats into the stem under ground, it devours the leaves. Sometimes, owing to over-feeding, it will remain at the base of the plant. When the Pinks have made some growth in April, it is a good plan to give a surface dressing with decayed stable manure, and when dry weather sets in water copiously once or twice a week.

The quantity of water required and the frequency of applying it will depend greatly on

the nature of the soil. If the soil is heavy and water does not pass away freely, it might not be required often or at all. On the other hand, if the soil is light, over gravel, the maximum of water may be needed. Neat sticks should be used to keep the flowers from the ground. Very little gardening skill is needed to grow Pinks.

All that is necessary is good garden soil, well aerated before planting, the ground between the plants to be kept free from weeds. The layering may be done when the plants are in flower, or after blooming time is over. The slips are also in the best condition to take off when the plants are in flower. In dry seasons seed may be saved from plants in the open garden, but in wet, cold seasons

service annually. I have been asked if this Mule Pink is still in existence. I do not know, but I doubt it. I grow a Pink named Napoleon III., which is evidently a cross between a Sweet William and a Pink, as Fairchild's also was. The Carnation and Sweet William, as well as the Pink, have been cross-fertilised. They are of the same genus, but are distinct specifically.

The best laeod Pinks known to me at present are Amy, Bueno Retiro, Brackleen, Capo di Monti, Chantilly, Clara, Empress of India, Excellent, Godfrey, Harry Hooper, Lufra, Minerva, Mrs. Pomeroy, Mrs. Welsh, Mrs. Waites, Morna, Old Chelsea, Reliance, Rainbow, Sarah, The Rector, Wedgwood, and Zurich. Of others than laeod Pinks, the best are Albino,

SUMMER FLOWERS IN THE GARDEN OF MR. S. FRYETT, LEWISHAM.

it will not ripen even in the south of England. I cultivated the Pink for many years in Scotland, but was never able to save any seed there. The capsules should be dried and the seed may be taken out in two weeks after gathering the capsules. I may add that one of the Pinks often enquired about is the Mule Pink. One of the earliest, if not the earliest, hybrids raised in England was a Mule Pink.

We are indebted for it to an amateur of Hoxton, a Mr. Fairchild. This must have been raised about the middle of the seventeenth century or earlier, as Fairchild died in 1667. I believe this worthy man must have instituted the first flower service, as he left a sum of money to the preacher of his parish that he might hold a flower

Anne Boleyn, Clove Pink, Her Majesty, Homer, Paddington, and Oriel. J. DOUGLAS.

A GARDEN NEAR LONDON.

We often hear of the difficulties of growing plants in and around London. Yet these are often more imaginary than real. During the past summer and autumn I had opportunities of visiting a good many suburban gardens, and found in most instances that both flowers and fruit could be well grown. The illustration represents a portion of the gardens at Holme-hurst, Lewisham, the residence of S. Fryett, Esq., who is an enthusiast, and in Mr. T. G. Goldring, his gardener, he has a most capable man to carry out his ideas. Mr. Goldring is a man who always seems to know what to plant, and the

garden is kept bright and interesting for most of the year. For summer bedding Fuchsias are favourites, and in sheltered spots these flower continuously throughout the season, even the double varieties, such as Ballet Girl, do well. Tuberous Begonias also keep up a bright show. Single Petunias planted round standard Roses are a great success. Zonal Pelargoniums are used, but not too extensively. Marguerites associated with *Salvia splendens* on a dry sunny border make a fine effect. The side borders are planted with a good selection of herbaceous plants—*Rudbeckias*, *Phlox* (perennial), *Gypsophila*, *Pyrethrums*, with *Gladiolus* standing up in showy clumps. A good selection of flowering and evergreen shrubs is also to be seen. Altogether the garden may be regarded as showing conclusively that with careful management a suburban garden may vie with many of those in more favoured districts. Mr. Goldring does not confine himself to the open garden; the conservatory is always kept gay. Among his favourites, of course, is the *Chrysanthemum*. *Cannas* are well flowered, also *Gloxinias* and Ivy-leaved *Pelargoniums*, although the convenience under glass is limited. Mr. Goldring always proves one of the most successful exhibitors at the local flower shows. A. HEMSLEY.

## NOTES ON HARDY PLANTS

### GALANTHUS FOSTERI.

It seems only yesterday Mr. James Allen read his paper on Snowdrops before the Royal Horticultural Society on March 10, 1891, which paper was published in *THE GARDEN* of September 19 of that year. Among the species described which were then but little known was *Galanthus Fosteri*, of which now, as then, rather conflicting opinions have been expressed. At the time Mr. Allen wrote his paper *G. Fosteri* had been so recently introduced that a critical opinion could not be expressed about it, for it was only first brought from Amasia in 1889 by Professor Foster (now Sir Michael Foster), in whose honour it was named by Mr. Baker. Thus the experience recorded by Mr. Allen was a short one, his plants having first bloomed in 1890, from bulbs planted in January of the same year. It will be well, however, to recall what our great Snowdrop specialist said of *G. Fosteri* at that time. "For one thing," he says, "it did not come up to my expectations; but I think it is scarcely fair to pass judgment on it before it has grown in our gardens for some four or five years, so as to develop its true character." Then he goes on to say: "This seems to be the most sportive of all the *Galanthi* as to size, form, and marking of the flowers. From the comparatively few bulbs I have already bloomed, I have had flowers with petals of every imaginable shape, some showing points of great beauty, and others quite the reverse. We must be patient and weed out unsparingly, and then in a few years we shall be proud of *G. Fosteri*. The markings on the inner petals are very similar to those of *G. Elwesii*, but the foliage is quite different, being broad and somewhat blunt, and in shape and colour like the leaves of *Scilla sibirica*." I have quoted Mr. Allen at some length, because he has put so clearly his opinion of *G. Fosteri* at that time, and because his judgment is one which has been entirely corroborated by the experience of more than a decade, with the addition of our having discovered that it is not everywhere that this Snowdrop will grow.

Since the date of Mr. Allen's paper *Galanthus Fosteri* has been rather largely imported, but it is to be feared that the proportion of inferior flowers has largely predominated in the importations, until some have thought that the opinion of our experienced friend Mr. Max Leichtlin, who regarded it as the "King of Snowdrops," was for once at fault. It is the process of selection which

has been absent, for there are some good forms; while, on the other hand, there are some which are very poor. The first form I procured, which I have still, is a poor one indeed, and I have often thought of weeding it out. But there are better ones, and it is unfortunate that the slow increase of this Snowdrop is against the multiplication of these good forms. Then the question of longevity has puzzled some. Whether it is that our winters are against it, or, it may be, that the soil is unsuitable, it is to be regretted that *G. Fosteri* has but a short life in many gardens. Here it has survived a long time, and I am inclined to attribute this mainly to the light sandy soil, and also to the partial shade in which I have grown it. Were it not that I have known of so many losses, I would not have doubted its hardiness and permanency. It must be remembered in connexion with this, however, that it has been thought to be a hybrid of *G. Elwesii* and *G. latifolius*. The latter is not a good doer with us, and even the former, in some of its forms at least, is not so enduring as one would have liked. I need say nothing further about its appearance, as the quotation from Mr. Allen, in which he speaks of the markings of the flowers being like those of *G. Elwesii*, and of the resemblance of the leaves to those of *Scilla sibirica*, fully indicates the general appearance of the plant. Its bulbs are fairly large, but I have seen none which bear out the information given to Mr. Allen, that they were in some cases about the size of a good-sized *Narcissus* in their native habitats.

*Carsethorn, by Dumfries, N.B.* S. ARNOTT.

### NYPHÆAS OF THE ODORATA GROUP.

I HAVE been for many years much interested in hardy Water Lilies, being—I think I may say—one of the pioneers of growing them in small tanks, as an article in *THE GARDEN* of February 3, 1896, will bear witness. My little tank—it is only 18 feet by 6 feet—has been imitated by at least two gardeners of widespread repute throughout Great Britain, and I have grown, with a fair meed of success, a considerable number of varieties; but I cannot keep for any length of time the varieties of the *Odorata* section, and would be very grateful if some growers of wider experience than mine would tell us how they have fared, for most others with whom I have had the opportunity of exchanging views have had much the same story to tell as myself. The plants do fairly on arrival, better the second, and perhaps the third year, leading one to think them well established, and after that they begin to go down the hill, breaking up into numerous small weak crowns, that flower badly or not at all, and another year or two sees the end of them.

My pool is of concrete, about 18 inches deep; the plants are in pots or boxes according to size. There is no flow through, the loss by evaporation being made up from the house supply, and the water being fully exposed to the sun becomes very warm, sometimes 70° to 75° after a hot July day.

The *Nymphæas* of the *Marliacea* section have all done well for many years. *N. M. albida*, *carnea*, *rosea*, *chromatella*, *gladstoniana*, also *Laydekeri rosea*, *pygmæa*, and *N. p. Helvola*, &c. Of the *odorata* forms I have had *exquisita rubra*, *sulphurea grandiflora*, *caroliniana*, and the type. All these have blossomed once or oftener, but none are now left. *N. Ellisii* and *Frœbeli* are more recent additions, but so far doing well. *N. tuberosa* *Richardsoni* is extremely good, but I fear it has gone the way of its relatives the *odoratas*. I am disposed to try some of these again, but am anxious for any information obtainable before doing so.

GREENWOOD PIM.

### CARDAMINE RHOMBOIDEA PURPUREA.

ANY green thing that shows signs of vigorous life at this season is a source of pleasure to a plant lover. Of course, it is easy to surround ourselves with all that heart could wish in wealth of leaf and blossom where ample accommodation exists, but many have to be content with only a small plot of garden ground, a tiny unheated greenhouse,

may, it may be, merely a porch or a window-sill, in which to satisfy the craving for an environment of growing plants. Any such may be reminded that the double Cuckoo-flower (*C. rhomboidea purpurea*) is one of the prettiest things to propagate during these dull winter months. It is a humble little plant, not much more than 6 inches high when in flower, in spite of its monstrous long name, but no one in early spring to whom it is not familiar passes by its dressy little cushions on the edge of the border without some word of admiration, and it is unique in this respect, that it wakes up just when most of its neighbours are thinking of going to sleep. Gather a few of its pinnate leaves in late November or even December, and peg down the slender stems, or snip off the pairs of leaflets if you like it better, dotting them by their half-inch length of stalk over the surface of a pan, keeping them fairly moist, and watch the result. Little silver threads will soon run out from the axils of the leaflets and find their way into the damp earth. Presently tiny bulbils will make their appearance, which quickly develop into buds, and before long you will be charmed to find a whole posse of bright green miniature plants springing up from every joint and even from the larger nerves of the dark fleshy leaflets. Nothing can be prettier than to see these brave little plantlings starting into life on their own account, rejoicing in the shelter of a roof over their heads, but afraid of neither frost nor cold so long as they are protected from keen winds, which in the open ground soon shrivels up too precocious efforts. Examine a plant in the border and you will find plenty of the little nurslings nestling in the bosom of the mother plant, but none on the outer and more exposed leaves.

This little double *Cardamine*, with its somewhat prim and Quaker-like spikes of pale purple flowers, which come about the same time or perhaps a little earlier than the Cuckoo-flower of the meadows, is scarcely so well known as it deserves to be. There are double-flowered forms of the common Cuckoo-flower (*C. pratensis*) which may often be found growing wild in the spring, some of the best of which are quite worth transferring to the garden by the same easy mode of propagation, but these are merely tinted white, and not distinctly mauve, or of that tone of colour which, nowadays, is mis-called *heliotrope*, besides being taller and looser in growth than the dainty little gem now under consideration. Whether autumn-springing plants such as these, which are at present in a cold greenhouse, will be strong enough to flower this spring remains as yet an open question, but propagation by leaf-buds in the manner described may be carried out at almost any season when leaves are to be found, and may chance to be more convenient than by division of the root. The late wet season suited the plants well, for the neat tufts remained fresh and green throughout the year. In a dry spot it is apt to disappear altogether during the heat of summer, but springs again with autumn rains and coolness. Belonging naturally to the marsh, it should be planted by preference in moist ground, where it flourishes exceedingly and increases without becoming too troublesome. But it is as a pot plant for early flowering in the alpine house or any modest unheated structure that attention may be directed to this lowly but pretty and interesting as well as hardy American perennial. K. L. D.

## THE LILIES.

(Continued from page 23.)

*L. DALHANSONI* (*L. Martagon dalmaticum* × *Hansonii*).—A lovely richly-coloured hybrid Lily, whose flowers are very stout and massive and of a rich mahogany tint. Bulbs white, conical, the scales arranged as in *L. Martagon*. Naturally small. Stems 4 feet to 6 feet high, dark purple below, greenish above, producing a few roots from their bases. Leaves in three to six whorls, a few scattered, broadly lance-shaped, dark green, 5 inches to 6 inches long.

Flowers ten to twenty in an elegant spike, each 3 inches across, not recurving to the extent of *L. Martagon*, dark mahogany-purple, marbled on the inner surface with bronzy yellow. The spikes are compact, yet elegant, and the surfaces of the petals are very lustrous. Rare in cultivation, but exceptionally easy to grow. Flowers in July.

**CULTURE AND USES** as for the European Martagons. This plant grows well in any plant border where the ordinary *L. Martagon* thrives. Our strongest colonies are growing in a thin tangle of roots from a small fence with ordinary border plants. The subsoil is clay, and in lighter soils this Lily would require all the moisture it could get and greater exposure, the protective plants being only of use in withdrawing excessive moisture from a naturally wet soil.

*L. elegans* (Thunb.).—A pretty dwarf Lily from the mountains of Japan, long cultivated by Japanese gardeners, who have produced some wonderful varieties, of which about twenty are grown in this country. Their colour schemes and form of flower are remarkably diversified. The whole group is very easy to grow, and their dwarf stature, vivid colourings, exceedingly large flowers, and accommodating habits render them very valuable for every garden use. Bulbs generally compound, white, small, miniatures of *L. umbellatum*. Stems 12 inches high, deeply channelled, stout, green, woolly above, rooting

freely from their bases. Leaves about twenty, lance-shaped, 3 inches long, often very broad near the inflorescences, glossy green, woolly when very young. Flowers woolly in a bud state, one to three in number, orange-red, erect, 4 inches long and wide, the petals spoon-shaped and slightly spotted below, the spots merging into two ridges which traverse the length of the claw. Flowers in July. Common in cultivation.

*Var. Alice Wilson*.—A charming variety now almost lost to cultivation. Stems a foot high, bearing one to three broad-petalled lemon-yellow flowers 6 inches across, spotted low down with chocolate. Always a rare plant, it is now quite unobtainable in even small quantities, the rarest and handsomest of its group. Flowers in July.

*Var. alternans*.—See var. *brevifolium*.

*Var. alutaceum* (Baker and Dyer).—A dwarf early Lily, whose flowers and growth are free from any woolly covering, the stems and leaves both stout and short. Flowers one to three, narrow-petalled, each 6 inches across, rich apricot, tinted yellowish near the tips, spotted black below, and irregularly flushed silvery grey externally. They are generally as long as the stems, and do not expand widely. June-July. Common in cultivation.

*Var. alutaceum grandiflorum* is a massive petalled form, whose flowers are much longer than the stems, and they expand more fully. Colour scheme similar. *Alutaceum* is found under an infinity of names in Continental gardens.

*Var. aurantiacum* (Hort.).—See var. *bicolor* (Moore), var. *aurantiacum verum*, the True Light Orange *L. elegans*.—A very pretty and striking form, with stems 18 inches high, glabrous, and the flowers expand widely, coloured a soft lemon yellow, with delicate salmon shading; three to six are borne on each stem, and they closely resemble var. *venustum*. Flowers in July. Common in cultivation.

*Var. aureo nigromaculatum*.—See var. *alutaceum*.

*Var. armenaicum* (Baker and Dyer), the Beautiful *L. elegans*.—A tall variety, resembling *L. Batemanniae* in many of its more important characters. The bulbs are large; stems 1 foot to 2 feet high; leaves linear, arching, and slightly twisted. Flowers in a compact spike of four to six, soft pale orange, the surfaces glistening, and the petals open quite wide and reflex at the tips.

*Var. macranthum* is a larger cultivated form, with flowers 6 inches across and 6 inches to 8 inches to the umbel, coloured

a richer orange. Flowers in mid-July. A lovely form. In our judgment the best and most beautiful of its group. Common in cultivation.

G. B. MALLETT.

(To be continued.)

LILIAM AURATUM.

I SEND you rather a pretty picture of *Lilium auratum*. The photograph was taken in the south of Scotland in November.

*Skipton-in-Craven*.

W. D.

THE ROSE GARDEN.

NEW AND LITTLE-KNOWN DECORATIVE ROSES.

TEA-SCENTED.

**A**LBERT PATEL.—A delightful Rose, with quite a small flower, but of perfect form, and the colour rich bronzy red with yellow shading. The growth is sturdy, and quite stiff for a Tea; in fact, this variety seems to be a near approach to the Hybrid Teas. It is the result of a cross between *Ma Capucine* and *Beauté Inconstante*.

*Chameleon*.—A fine grower, much resembling *Anna Olivier*; the flowers are large, rosy flesh in colour, with a distinct blotch of deep rosy crimson at the base of the outer petals. This blotch is somewhat variable, hence doubtless its name.

*Comtesse Olivier de Lorgeril*.—One of those mixed colours of which *Souvenir de Lady Ashburton* is typical. It is a lovely Rose, one that is sure to please.

*Comtesse Sophy Torby*.—In the way of *Souvenir de William Robinson*, the red outer petals being very conspicuous against the coppery yellow and peach tints of the inner petals.

*Dainty*.—The elegant clusters of this Rose, borne erect upon fine stems, make it a very conspicuous variety in the garden, and the dainty little primrose-yellow buds edged with carmine are most charming.

*Mme. Antoine Mari*.—One of the best, if not the best, decorative Rose of 1902. The buds are of beautiful shape, each one heavily shaded with rose on a white ground. The growth is compact and vigorous. A worthy companion to *G. Nabonnand*, *Corallina*, *General Schablikine*, &c.

*Mme. Jean Dupuy*.—A fine flower for exhibition, yet sufficiently free to be a decorative variety too. The general effect is rosy yellow, but at times it resembles *Mme. Lambert*.

*Mme. Louis Poncet*.—One of those charmingly-tinted Roses of the *Mme. Eugene Resal* type; in fact, it seems to me to be as much a China Rose as the latter, but perhaps I should say *Mme. E. Resal* is more of a Tea-scented variety. The colour of *Mme. L. Poncet* is *nasturtium-red*, with a coppery shading. An excellent bedder.

*Morning Glow*.—The prevailing tint of this splendid bedder is orange red, with other shades combined. The growth is first-rate, and it must soon take a prominent position among decorative Roses.

*Peace*.—When I say this is supposed to be a lemon-white sport of *G. Nabonnand*, I can give it no higher recommendation, and it should be largely planted for massing where the parent has been found to succeed.

*Mme. Berkeley*.—A real beauty to all who admire these large-petalled semi-double Roses. The colour is creamy white, tinted flesh-pink. Of the same style of flower as *Yvonne Gravier*, but with the growth a little more erect.

*Préfet Montell*.—In the way of *Marie Van Houtte*, but the growth is more compact. This will doubtless make a splendid bedding Rose.

*Salmonea*.—A very distinct Rose, the salmon-coloured centre, with bordering of bright crimson, gives the variety a charming appearance.

LILIAM AURATUM IN THE SOUTH OF SCOTLAND.  
(This photograph was taken in November of last year.)

*Sulphurea*.—Flowers sulphur-yellow, of perfect shape; rather more than semi-double, growth grand, foliage rich coppery red. A really excellent variety, and a great advance upon Isabella Sprunt.

*Vicomtesse R. de Savigny*.—Here again we have a peculiar yet beautiful blending of colour. The centres are pale yellow, with the outer rows of petals a dark rose. Very free blooming; form excellent.

#### POLYANTHA ROSES.

*Aschenbrüdel*.—A charming miniature Rose, likely to be in much request. Colours, peach with orange shading.

*Katherina Teimet*.—Large clusters of snowy white flowers. An improvement on Paquerette. Lovely as a pot plant or for bedding.

*Mme. N. Levasseur*.—Not so bright as it has been represented, but certainly a long way towards realising that desirable

*Comtesse de Cayla*.—This will probably surpass all the other varieties of this race, which began with Laurette Messimy. The colours are rich and striking, nasturtium-red, orange and coppery yellow, with a carmine shading.

#### RUGOSA.

*Conrad F. Meyer*.—A grand Rose for any purpose—hedge,

imagine the latter are by far in the majority, and these varieties should certainly receive attention from those who make Rose growing a study.

PHILOMEL.

## NEW AND RARE PLANTS.

### CROTON TURNFORDIENSIS.

SHOWN in the accompanying illustration is one of the most distinct varieties of the Croton exhibited for some time. When shown by Messrs. Thomas Rochford and Sons, Turnford Hall Nurseries, Broxbourne, before the Royal Horticultural Society, on December 15, 1903, the floral committee gave it an award of merit. This new Croton is stated to be the result of a cross between the old *C. variegatus* and *C. Thomsoni*, the influence of the latter variety being apparent in the broad leaves.

It reminds one in growth and general appearance of *C. Delight*, *C. Hawkeri*, &c., yet it is quite distinct from any by reason of the rich golden, almost orange, yellow in the centre of the leaf, which has a broad margin of deep olive green. It has the hardy character of *C. variegatus*, and therefore may be perfectly well grown in a fairly low temperature. Croton Turnfordiensis should prove to be a most useful decorative plant, its bright, distinct colour and good habit make it all the decorator could desire. The accompanying illustration shows just the top of a shoot, and the leaves are sketched natural size, the lower ones, of course, are larger.

illustration shows just the top of a shoot, and the leaves are sketched natural size, the lower ones, of course, are larger.

CROTON TURNFORDIENSIS.

(The drawing was made from the top of the plant.)

acquisition, a dwarf perpetual-flowering Crimson Rambler.

*Philippine Lambert*.—In the way of Cecile Brunner, but quite distinct, and one worth growing.

*Schneewitchen*.—Fine pyramidal clusters of yellowish-white flowers. The numerous yellow stamens somewhat spoil the effect.

#### CHINA OR MONTHLY ROSES.

*Arctusa*.—This may be a yellow Queen Mab, as it resembles this charming variety in growth.

standard, pillar, anywhere where a vigorous free bloomer is required. Then what a delightful soft shade of pink are its blossoms, and fragrant, too.

*Mercedès* is, for a Rugosa, a lovely colour, pale rosy pink, outer petals white. Distinct and fine.

The above-named Roses are all really good, and no one will regret planting them. I maintain they will, as novelties in garden Roses, be far more serviceable to those who do not exhibit than many of the much-praised novelties in exhibitors' Roses. After all, there are only two classes of Rose growers, those that exhibit and those who do not, and I

### FROM COPSE TO COTTAGE.

WHERE a dwelling adjoins woodland it is a pleasant task to work out ways of bringing together the nearer ground and the wood, so that they meet easily and seem to come together without jolt or jar or incongruity. The grassy path in the picture branches out of a strip of turf on the south side of the cottage; the lawn stretching out farther and wider in its western face. This grass path is one of several that lead into the copse, which slopes upwards towards the south. To the right is a mound, to the left a slight hollow. In this are Sedums,

FROM COPSE TO COTTAGE.

Kalmias, and dwarf Rhododendrons, with handsome foliage of Rodgersia, Saxifraga peltata, and hardy Ferns. On the bank to the right are Junipers, Andromeda floribunda, Skimmias, and again dwarf Rhododendrons, these being myrtifolium and the alpine kinds. Large lumps of sandstone show here and there among the flowering bushes in stratified ranges as if they were cropping naturally out of the ground. In the foreground is a rough stone seat and some steps leading to the wooded ground above.

## THE INDOOR GARDEN.

### NEGLECTED GREENHOUSE PLANTS.

IF gardeners fully realised the great value of such a plant as Jacobinia chrysostephana, which bears heads of orange-coloured tubular flowers at the duldest period of the year, *i.e.*, during December and January, they would never fail to have a good number in their glass houses. It is indispensable at this time of year, not only for the decoration of the intermediate house, but it may also be used successfully for house decoration. In this respect it is the best of the Justicias or Jacobinias, for the flowers last well. It is astonishing how long plants in flower will keep fresh and bright providing the weather is not very foggy—they will remain in good condition for five or six weeks. The dark green leaves of this Jacobinia contrast well with the bright flowers whose colour seems almost glowing when seen on a dull December day. One reason why everyone who values brightly coloured winter-blooming plants should grow Jacobinia chrysostephana is that it is of quite easy culture. Plants to flower in the winter may be readily raised from cuttings inserted in May. They root without difficulty if placed in

small pots filled with sandy soil, which are put in a warm house. They should be stopped once so as to give two shoots, two heads of bloom may then be expected the following winter. The same plants grown on again the next year, if stopped, would have at least four shoots, and each of these crowned with the brilliant flowers makes a splendid plant. This Jacobinia does not require stove temperature; in fact, it does better in an intermediate one, the growths made under these conditions are stronger and flower better. The group of plants shown by Messrs. James Veitch at the Drill Hall, on the 5th inst., made a brilliant bit of colour, and fully demonstrated the great value of this winter-blooming plant.

The old *Justicia carnea* with heads of pink flowers is also well worth growing for winter blooming. It *i.e.* ds the same treatment as advised for *J. chrysostephana*. Cuttings inserted in May will produce flowering plants by December, and if cut back and grown on for another season they will, under cool treatment—in fact they may be grown

in frames during the summer months—give an abundance of flowers the following winter and spring. A gardener of long standing says: "I remember some thirty years ago this plant was much grown. The old plants were cut back about July and placed in a warm pit to break. When growth commenced they were shaken out, potted, and returned to the pit. As the days shortened they were placed in a vinery just started, and here they gave an enormous amount of flower in the months of February and March." *Peristrophe speciosa* (*Justicia speciosa*) is another plant whose value is under-estimated. In my opinion it is second to few winter-blooming plants for conservatory decoration. The flowers do not last so long and the plants will not stand so much moving about with impunity as *J. chrysostephana*, but if groups are arranged in the greenhouse and left undisturbed it is always admired. If wanted especially

for table decoration, small plants in 5-inch or 6-inch pots may be had in the autumn; if larger and later blooming plants are required they must be repotted into larger pots. The colour of the flower is uncommon, and therefore welcome; they may be, perhaps, best described as purple, although a reddish tinge is noticeable throughout. *Euphorbia pulcherrima* is not heard of so frequently as it used to be, yet for flowers at Christmas and early in the new year it is a plant not lightly to be ignored. It is equally useful as a pot plant or when the long growths are cut. The cut sprays are extremely effective for room decoration, the bunches of bright red bracts showing conspicuously against the rich green foliage. Cuttings should be inserted in spring as soon as

good ones can be obtained. The young plants may be grown in pits during the summer, but as soon as the nights begin to get cold they must be removed to a warmer house. When the bracts begin to show colour they benefit by increased heat and as much light as possible. If the stems are cut for house decoration, it is recommended to dip them in hot water before using; this drives the sap up towards the bracts, and thus prevents its loss. A. P. H.

## BOOKS.

### Some lesser known Japan Trees and Shrubs.\*—

We have received from Mr. James Veitch a little booklet, containing the paper read by him before the Royal Horticultural Society last year. It is freely illustrated, and two of the illustrations we reproduce, one of *Vitis megaphylla*, and the other of *Spiraea Henryi*. Of the former the author writes: "*Vitis megaphylla* (the wonderful-leaved Vine) is remarkable in having bipinnate leaves, in this respect resembling the allied genus *Leea*. The leaflets are petiolate, 2 inches to 4 inches in length, ovate, with dentate margins." Of the *Spiraea* Mr. Veitch says: "The genus *Spiraea* is represented by many showy species, of which *Spiraea Henryi* is probably the best. It is a shrubby plant belonging to the *Spiraea canescens* group, furnished with ovate leaves, 1½ inches to 1½ inches long by half an inch to three-quarters of an inch broad, serrated along the apical margin of the leaf, slightly pilose on the upper surface, and densely so underneath. The flowers are produced in dense corymbs terminating dwarf shoots along the whole length of the branches. They are small individually, pure white, and very showy in the mass." We need not refer further to this pamphlet, as the lecture was published in *THE GARDEN* last year.

## CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

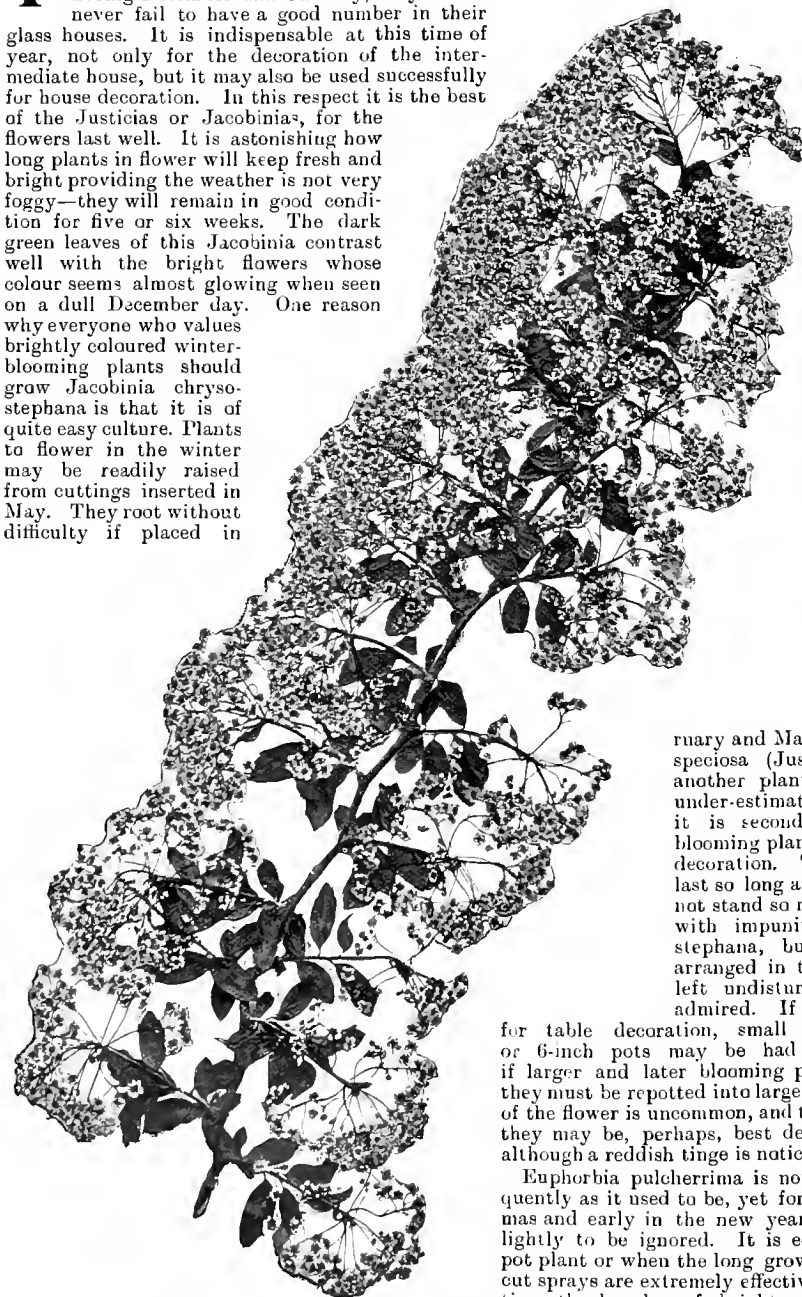

### FRUIT TREE PRUNING.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—In his reply to my criticism Mr. Thomas has confined himself to side issues, and does not deal with my contention, which I now repeat, *viz.*: "That the knife applied to the main leads never yet assisted in the production of fruit buds on a tree that has not reached its prime." On this, as far as I am concerned, the whole matter rests. Again I wrote: "Hard pruning . . . is misused as a means of forcing them (the trees) to produce fruit buds, a thing that hard pruning . . . never did and never will do," *i.e.*, that hard pruning is no factor in the production of fruit spurs. Mr. Thomas perverts this last sentence when he misquotes me as saying that trees pruned on this system "never did and never will bear fruit," a very different thing. I say that the fruit buds on hard-pruned trees come with age *in spite of*, and not by the aid of, hard pruning. I granted that pruning was necessary to confine trees to a limited space and to attain a certain shape or shapes, but in these days, when the selection of stocks is so carefully carried out in the best nurseries, half the old growers' difficulties in the matter of dwarfing have disappeared, while the cropping properties have been greatly enhanced.

Again, Mr. Thomas attributes to me a sentence which I did not write, *viz.*: "Every bud from tip to base . . . will break and develop a shoot." This is so foreign to my views and experience that I must repeat what I really said on the matter: "The result in the second year of abstention from shortening will be the production of *fruit spurs* or buds almost throughout the entire length of the leading shoots." Not a word about the side shoots there, though earlier I did the very thing I am

\* "Some Lesser Known Japan Trees and Shrubs, and Some Recently Introduced Trees and Shrubs from Central China." By James H. Veitch.

*SPIRÆA HENRYI* (Hemsl.). Flowers small, white, densely borne along the whole length of the previous year's growth.

accused of not doing, viz., I recommended the removal of surplus side shoots "that would be mischievous in the future." On the extension system properly carried out these side shoots do not occur to one quarter the number that appear on the same length of main stem on a hard-pruned tree; their place is largely taken by fruit spurs, and they give very little trouble. Mr. Thomas evidently understands this dearth of side shoots on unpruned branches, but I should not like to go to the length of saying, as he does, that they are "barren of fruit and foliage for all time." If this were true, where is my "muddle and tangle of growth" to come from?

I am pleased to see that Mr. Thomas considers the base and the middle the best part of the annual growth, but I am curious to know why he advises in his former notes that the middle shall be cut away. We are given from 18 inches to 30 inches as the average length of leading shoots. From this we have to take one-third at the summer pruning and from one-third to more than one-half again at the winter pruning. Where, then, is this valuable middle portion? In a tidy garden it has, of course, gone to the fire-heap.

I must again assert that no properly planted or properly managed dwarf tree will make long, spurless shoots that break only at the apex. Proper treatment at the roots, both at planting time and after, combined with the use of proper stocks, will give leading growths of moderate length that in their second season leave nothing to be desired in the way of fruit buds, and will supply also sufficient wood growth to furnish the tree if wanted, or to be cut out if not wanted for this purpose. Mr. Thomas is quite right to condemn long, barren growths, but his remedy is not the one most conducive to fruitful wood.

As an illustration of his theories Mr. Thomas chooses to place orchard house trees on a parallel with those grown outside. There is no such parallel; the conditions are quite different. Orchard house trees are grown generally in a very confined root-run, are very frequently root-pruned, and make under the pinching system (which differs very largely from hard winter pruning) and with the aid of a glass roof just the right kind of wood for fruit buds. The confinement in their case hastens maturity. A pot Apple or Pear tree that permits one-third of its growth to be cut or pinched off in August, and still has sufficient left to allow a further cutting back to 9 inches, or even 6 inches, would be an example of orchard house culture that would not, I think, be pleasing to the grower. Fortunately, after the first year or two of extension training, growth on a properly managed outdoor tree is not nearly so rapid as Mr. Thomas infers. By adopting the extension principle splendid fruitful trees may be built up in half the time required by hard-pruned trees covering the same ground. It appears to me that the aim in this country should always be to counteract grossness by inducing as best we can an early ripening of growths of moderate length, and I assume that there were fruitful trees in the world long before pruning was thought of.

I am aware of the fine fruit that may be grown in limited quantity on hard-pruned trees, and I have never found fault with them in this discussion, but only with the promulgation of the idea that hard pruning induces fruit bud formation. I hope

VITIS MEGAPHYLLA (Diels and Gilg). Leaflets  $4\frac{1}{2}$  inches long by  $2\frac{3}{4}$  inches broad.

it is not necessary for me to take a journey to the Channel Isles to see illustrations of good dwarf tree culture. If it be so, it speaks well for the rapid progress of extension training at home and the hold it has gained on growers. It was my fortune for many years to have charge of a considerable number of trees grown on both principles, and careful observation of these has helped to build up my practice as an extension trainer wherever possible, and I may add that I worked many of these trees from the graft to the time of fruiting and after. Turning to Mr. Thomas' illustration, supposing the child, who is on or about the level of the top of a six or seven-tier wire fence, to be 3 feet high, the lowest branch must be 5 feet from the ground—a bad beginning for a dwarf—and the tree apparently little less than 20 feet high and nearly as broad. Yet we are told that by following the method of pruning indicated three or four specimens of good size can be grown on the same area of land as would be taken by one tree grown on the "let-alone" (by which Mr. Thomas designates the "extension") principle. Plenty of extension trained trees cover more space and are fruitful years before the tree illustrated could have reached half its age and size. Many orchard trees in their prime reach no higher, though they may cover more space, but why should we be concerned to grow more trees on a given area than is necessary to cover it? Is it to get more variety? If so, the reason is a bad one from the market grower's point of view. Can anyone look at the disposition and character of the branches in Mr. Thomas' tree, crowded in parts and thin elsewhere, and call it even a tolerable representation of a dwarf tree? The summer pruning, too, has apparently been forgotten. In his earlier article we are told by Mr. Thomas to leave at the summer pruning side shoots with seven leaves, and at the winter pruning to cut these to within two or three buds of their base . . . "but if the summer pruning of these trees has been properly attended to there will be very little winter pruning required." Which does he mean? Surely the side shoot pruning is the greater part of the business, and as all these shoots,

if pruned in the first instance to seven leaves as advised, have to be again shortened, I fail to see the lessened labour at the winter pruning.

J. C. TALLACK.

## GARDENING OF THE WEEK.

### FRUIT GARDEN.

#### MELONS.

**W**HERE Melon houses are at command, with plenty of top and bottom-heat, good fruits can be obtained by the first week in May. It is waste of time to attempt to grow very early Melons without plenty of heat and moisture. Thoroughly clean the house and make up a good bed of leaves over the hot-water pipes. I prefer 12-inch pots for the earliest batch, and to sow two seeds in these pots. Stronger plants are obtained that will grow better at this season than if sown in 3-inch pots. Provide drainage, and three parts fill the pots with fairly strong loam; add lime rubble, wood ashes, and a little bone-meal; make firm, and keep the soil highest in the centre of the pot. Plunge the pots close together in the leaves, standing them on an inverted pot. Keep them near the glass, sow two seeds in each pot when the soil is well warmed through, removing the weakest plant later. If planting out is preferred, the same compost placed in ridge form, sowing the seed in position, will answer equally well. There are so many varieties of Melons now that each grower has his own favourite variety. The scarlet-fleshed varieties are generally earlier, and two good early sorts are Frogmore Scarlet and Turner's Scarlet Gem. Select the first fruits that show, and, if grown in pots on the single cordon system, allow two fruits to a plant. Stop the shoots second leaf above the fruit, and pinch out all side shoots. Maintain a night temperature of 68°, allowing a rise of 10° or 15° from sun-heat. Secure a moist,

growing atmosphere by frequent dampings of the paths and beds.

#### PEACH HOUSES.

Peaches which are set should have the temperature raised to 55° at night. The fruits should be thinned early if set thickly, leaving the largest and best placed. Disbudding should be performed at different times, finally leaving one shoot at the base and a leader. No more shoots should be allowed to remain than are necessary to secure a good crop of fruit and to furnish any vacant space. Trees in bloom should have a temperature of about 50° at night. Go over the flowers daily with a camel's-hair pencil when the temperature is highest. Give the trees a constant circulation of air, and discontinue syringing the trees until the fruits are set, damping the paths and borders only. Keep a sharp look out for fly, and fumigate at first appearance.

#### STRAWBERRIES.

Continue to fertilise the flowers daily, and give plenty of air on all favourable occasions. As soon as the fruits are set give weak liquid manure water, and syringe freely to prevent red spider. A drier atmosphere must be kept later; it will improve both the flavour and colour of the fruit. Introduce later batches of plants at intervals. Suspended shelves in Peach houses are useful for these, as the syringe can be plied well around them. Examine them carefully before flowering for fly, and fumigate if necessary.

#### FIGS.

Trees in pots should be kept in a steady bottom-heat of 75° to 80°. Thin the fruits early, and top-dress with a rich compost. Keep the roots in a moist condition by watering with liquid manure, syringing the plants twice daily. Clean and top-dress later houses, using plenty of old lime rubble, and make ready for starting. F. JORDAN.

*Impney Gardens, Droitwich.*

#### FLOWER GARDEN.

It is important that vacant beds be well and deeply dug. This will not only provide a good root-run, but during a dry summer the occupants of beds or borders so treated will withstand drought far better than if the digging is but lightly done. Where the beds are of intricate shapes a watchful eye must be kept on the corners and points, for if the work is not thorough these portions will be unsatisfactory throughout the summer. The nature of the dressing must be determined by the class of plant it is intended to grow in the beds. If any addition to these beds is considered necessary some old soil from the potting-sheds will give better results than manure. Tuberos Begonias revel in a rich deeply-worked soil. The beds for such gross feeders as *Lobelia cardinalis*, *Cannas*, *Dahlias*, &c., will require liberal additions of well-rotted manure, and a sprinkling of bone-meal worked in with the soil will be found beneficial.

#### HERBACEOUS BORDERS.

As weather permits these should receive attention. All dead stalks, unnecessary stakes, &c., should be cleared away, remembering that the stems of such things as *Michaelmas Daisies* make capital stakes for some plants that require but a slight support. We have had such an abnormal rainfall, and the growth of some plants has been so luxuriant, that in many cases the borders will be found to be considerably impoverished, and it will be necessary to fork in an extra quantity of dressing. Many strong growers will require to be restricted; where practicable, the whole clump should be lifted, and the necessary portions for replanting taken off from the outside of the mass. Replanting should be done firmly, and, if frost is anticipated, it will be advisable to apply a light mulching.

#### BEDDING PLANTS.

All decaying leaves must be cleared away. In picking over *Pelargoniums* (*Geraniums*) the stalk of any decaying leaf should be removed with a slight downward jerk, as the decay is frequently transmitted to the stems by decaying leaf-stalks. If the stock of *Dahlias* or *Cannas* is short these roots should be divided, potted, or boxed, and

placed in moderate heat. Seeds of *Cannas*, *Grevillea robusta*, *Begonia*, *Cordyline australis*, and kindred plants, if sown now and placed in a brisk bottom-heat, will produce plants fit for this year's summer bedding. *Grevillea* seeds should be sown edgewise; the hard *Canna* seeds will germinate quicker if the outer covering of the seed is carefully chipped with a knife or filed. If preferred, soaking in hot water for a couple of days will soften the shell. The minute seeds of *Begonia* must be but thinly covered.

Carefully press down with the hands any *Carnations* that have been lifted by frost. Fill up from the reserve all blanks in the beds of such as *Wallflower*, *Silene*, *Polyanthus*, *Myosotis*, &c.

A. C. BARTLETT.

*Pencarrow Gardens, Bodmin.*

#### KITCHEN GARDEN.

At the time of writing the weather is such as to put a stop to all work in the kitchen garden. Attention may now be turned to the raising of various vegetables that require to be sown under glass.

#### CAULIFLOWERS.

A sowing may now be made in shallow pans or boxes of the earliest varieties. The chief point is to see that as soon as the seedlings come up they are kept always close to the glass. They should be grown in a rather dry house, as the young plants are at this season so liable to damp if the atmosphere is at all moist. They may be pricked out in boxes 2 inches each way, and grown as hardily as possible. Autumn-sown plants wintering in cold frames should be given as much light as possible and abundant air on all occasions, except during severe frost. Early *Erfurt* or *Snowball* are the earliest to come into use, and are therefore most suitable for present sowing.

#### TOMATOES.

A sowing should now be made of some early variety, using well-drained pots filled with light soil. The plants as soon as large enough to handle may be potted singly into small pots, and stood near to the glass in a warm pit.

#### ONIONS.

Where extra large or exhibition roots are desired, seed should now be sown of such sorts as *Ailsa Craig* or *Cranston's Excelsior*. Sow in rich, light soil, making it rather firm. As the seedlings appear, place near to the glass to prevent their becoming drawn and weakly. Prick out into boxes filled with rich soil and grow under glass till early in April, when they may be hardened off and planted out in specially prepared ground.

#### GENERAL REMARKS.

See that protection is given to *Potatoes* and other roots pitted in the open. A quantity sufficient for all requirements should be lifted and stored. If this has not been done, care must be taken to have the pits closed as expeditiously as possible. As long as frost continues push forward all carting or wheeling of manure. Inspect roots that are stored under cover, removing all those that show signs of decay. Get material together for the making of hot-beds, which may consist of fresh stable manure and dried leaves. This will be found a useful method for the forcing of early vegetables, such as *Carrots*, *Turnips*, *Radishes*, &c., where hot-water pits are not available. Supplies of *Rhubarb*, *Seakale*, and other roots for forcing should be lifted and stored in a cool place till required. Protect all roots still in the ground, such as *Parsnips*, *Celery*, &c., by giving a good covering of stable manure. THOMAS HAY.

*Hopetoun House Gardens, N.B.*

#### ORCHIDS.

##### ODONTOGLOSSUM HOUSE.

THE present season is the most critical part of the year in this house, the hard firing needed to maintain the correct temperature, and the inability to give air with freedom, has a tendency to weaken the foliage, making it very susceptible to that peculiar form of damping oftentimes seen on *Odontoglossum* leaves at this season. Judicious firing,

careful airing, and a humid, sweet atmosphere are the most essential points to be observed. Nothing reduces the vitality of

##### ODONTOGLOSSUMS

so quickly as that of being in a house where there is not a free admission of fresh air. I always prefer to put on fire-heat rather than take off all the top air, and it is very seldom our bottom ventilators are ever closed. On all bright days give them a good spray overhead. No plant should be subjected to the strain of flowering that has not made a growth equalling the preceding one, otherwise the strain on the plant will reduce its strength to such a degree that many seasons will be required for it to recuperate. Slugs have a great liking for the young *Odontoglossum* spikes, so to preserve them from their ravages traps should be nightly laid about the house and examined from time to time. A piece of *Orange-peel* is a great attraction to them. Another very good trap is that of laying a pinch of bran on pieces of cardboard. Any now in flower should have their spikes removed soon after expanding, the strain at this season being far greater than when flowering in April and May, when air can be admitted in greater quantities and firing nearly dispensed with.

##### DENDROBIUMS.

The deciduous and semi-deciduous section are now fast developing their flower-buds, and rather more warmth should be afforded them than they have been receiving since the resting period commenced; great harm is often done by allowing the plants to remain too long in their resting quarters. The plants must be given a temperature of not lower than 60° by night, rising to 70° in the day, as soon as the buds show signs of breaking from their sheath. Great discretion should be exercised in watering, only enough to retain the pseudo-bulbs in a plump state will be required for some time yet.

The flowers are of far more value during January and February than later in the season. The following are now in flower, or nearly so, with us: *D. wardianum*, *D. nobile* and its many beautiful varieties, *D. crassinode*, and *D. heterocarpum*. We look to the hybrids to produce our finest show, among them being the practically perpetual-flowering *D. × Curtisii*, *D. × Wigania*, *D. × wiganianum*, *D. × Cybele*, *D. × Melanodiscus*, *D. × schneiderianum*, and *D. × Rolfæ*. To maintain a collection of *Dendrobiums* in vigorous health, it is necessary that a certain number should be annually raised from cuttings. When retying the plants previous to flowering, any back pseudo-bulbs that are not required should be cut out, and on no account should more than two be retained. These should be correctly labelled and laid on a stage for the time being, and from those that have no old pseudo-bulbs, if there is a desire to increase the stock, cut off a bulb and lay on the stago till the season for propagation comes round. By removing the bulb at this season a portion of the sap is absorbed previous to the cutting being made, consequently there is less fear of loss by damping. W. P. BOUND.

*Gatton Park Gardens, Reigate.*

#### INDOOR GARDEN.

##### CROTONS.

So well do these plants lend themselves to every kind of decorative work that they are continually in request, and repeated propagation is necessary. Shoots with highly coloured leaves are the best to select as cuttings; insert these singly in the centre of 2½-inch pots in a compost of equal parts fine loam, leaf-soil, and sand, care being taken to make the soil around the base of the cuttings firm. Afterwards plunge the pots two-thirds of their depth in cocoa fibre in the propagating pit, which keep close; maintain a temperature of 70° to 75°, with abundance of moisture. Single stemmed plants are the best for the purpose, and as through continued use they lose many of their bottom leaves and look unsightly, propagation by ringing is advised as the most expeditious method of rejuvenating the stock.

##### GLOXINIAS.

The flowers of these are always admired, and the earlier in the season they are in evidence the more

they are appreciated. The most convenient method is to place the early bulbs in pans or shallow boxes, amongst cocoa fibre, and afterwards in any house that is kept close, and at a temperature of 60° to 65°. Pot them up singly into suitable sized pots directly they begin to make roots and show signs of starting into growth from the crown of the bulb. For late flowering nothing can be better than plants that are raised from seeds, which should be sown at once. The seeds are extremely small, and require to be sown with great care. A compost that suits them well consists of fine leaf-soil, sand, and cocoa fibre. The pots or pans in which the seeds are to be sown should be carefully and well drained, and the compost, previous to sowing, should be soaked well with water from a fine-rosed can. Scatter the seeds evenly over the surface of the soil, over these sprinkle a very small portion of fine sand, and to settle the seeds in a good bed

should be kept cool by admitting air and occasionally sprinkling the stages, &c. with water during bright and sunny weather. J. P. LEADBETTER.

## THE KITCHEN GARDEN.

PEA EDWIN BECKETT.

**T**HIS Pea, which received an award of merit at the Royal Horticultural Gardens, Chiswick, also a unanimous vote for a first-class certificate at the Royal Horticultural Society's meeting at the Drill Hall, Westminster, on July 3, 1900, still maintains its

position as one of the very finest Peas in cultivation, viewed either from an exhibition or a utilitarian point of view. Having grown it in considerable quantities during the past four years with the best possible success, a few notes may prove advantageous to any who are about to grow it for the first time. It has proved one of the earliest large wrinkled varieties in cultivation, and when well grown it is hard to beat, either for appearance or quality. One of its chief merits is its thorough hardiness. It has proved itself here to be quite proof against spring frosts and cold, cutting winds, being very much harder than Early Morn, which was one of its parents. It will produce pods from 5½ inches to 6 inches in length, which often contain eleven full-sized Peas, and it is also a great bearer. It is, moreover, a capital variety for growing under glass, either in pots or planted out. If the seed is now sown and brought along gently, good Peas may be looked for by quite the middle of May, as it is a very robust grower. Seed should be sown very thinly, from three to four plants in 8-inch or 10-inch pots being ample, and if extra fine pods are required for show purposes, after a reasonable amount of pods are set, the points of the growth should be pinched out, which will also induce them to

mature much more rapidly. For open air treatment much better results will follow if the seed is sown thinly in boxes, sufficiently so that each individual plant can be lifted out separately and planted in well-prepared trenches, allowing a distance of from 9 inches to 12 inches apart. Three sowings should be made in this way at intervals of a fortnight, after which two or three sowings should be made in the open.

Not only is it particularly well adapted for early supplies, but it is equally good for mid-season use, also for very late work, as it is seldom attacked by mildew. Like many other varieties of Peas, I understand from Messrs. Cutbush, of Highgate, who distributed it, that, owing to the past adverse season, the stock is somewhat

limited, consequently those who are anxious to grow it should lose no time in placing their orders. E. BECKETT.

## EARLY PURITAN POTATO.

**T**HERE has always been a shade of suspicion attached to this early American Potato that it is the white form of Beauty of Hebron only. It came from America just after Beauty of Hebron had, over here, been put into commerce in its white skinned form as Duke of Albany and as White Beauty. Grown side by side, in character and in bloom it was difficult to discern any distinction between Early Puritan and the white sport. We have had it under the above name some fifteen years. Whether distinct or not, it is an excellent first early variety, tubers rather long than round, very white in colour, produced in good abundance, and of nice appearance, tops of moderate height, spreading, flowers white. Of all the Americans that came to us so plentifully during the seventies and eighties of last century, Beauty of Hebron, with its pink skin, has proved to be the best. Now it is materially displaced by the white form and the variety here noticed—Early Puritan. A. D.

## THE FRUIT GARDEN.

### THE NEGLECT OF ORCHARD FRUIT TREES.

**N**EVER have I been quite able to understand why old and long-established orchard fruit trees should be so persistently neglected, and yet it is so. No one has need to travel far in order to see grass orchards in which the heads of the trees represent nothing but thickets of congested growth, while the stems and branches are covered with moss and lichen, as well as being natural harbours for the various insect pests that are detrimental to fruit. If one looks beneath the trees one sees rank grass growing that no animals would eat, but a palpable absence of any kind of manure that would assist the root and branch growth. Strangest of all, this unsatisfactory state of affairs may often be seen where the fruit trees within the garden enclosure receive fair and reasonable attention, and yet neglect is plainly written on the specimens in the orchard without.

It is not easy to fix responsibility for the neglect of orchard trees, and it seems as though one generation begins it and the next one follows it out. Little by little the heads become overcrowded for the sake of the timely hand of the thinner, until at last the work seems to be too stupendous to be taken in hand, and so it goes on till the end of the chapter. Volumes are spoken for the vitality of fruit trees when we consider that even under these neglected conditions they bear crops, but generally speaking the fruit is not good, neither does it win prizes at the show, or fetch the highest price in the market.

While discussing this subject I am reminded that there are many trees, whole orchards of them perhaps in some cases, where neglect has been going on too long, with the result that constitutions are undermined and impaired and the trees are too far gone to be renovated. In such cases remove them or let them end their career in their own way. There should, however, be no haste about it, as from my experience an orchard tree that has been neglected must be in a bad way indeed if it cannot be improved, and when once it is cut down there is no such thing as putting it back. Apart from the specimens about which there hangs a doubt as to whether they are worth spending time and trouble over, there are thousands of orchard fruit trees in full vigour that need timely attention. These are the trees that I particularly call attention to here because the present is a suitable time for taking them in hand.

Overcrowding of branch growth is the common evil amongst established orchard trees, but there are no fixed rules about thinning beyond that it should not be neglected. In fact, the

PEA EDWIN BECKETT.

press on the surface with a piece of wood or anything having a clean, smooth face. The application of water to the soil afterwards will seldom be necessary until germination has taken place, evaporation up to this time being kept in check by covering the seed pots with glass, and afterwards with paper, moss, or anything to exclude the light.

### CHRYSANTHEMUMS.

Cuttings of these that are rooted should immediately be removed from the propagating box and given a position near to the glass, so that light and air may act upon them and keep them dwarf and sturdy. It is advantageous also to shift them early into larger pots before their roots get very much entangled, and in so doing see that the new soil covers well the surface of the old ball. At no time must the plants suffer from lack of moisture to their roots, and their surroundings at all times

thinning out of the branches of a congested standard tree is entirely a matter of judgment, and in this, as in the case of many other operations, two heads are invariably better than one. Armed with a sharp saw one man should take his place among the boughs of the tree while his companion directs operations from beneath. The latter is in a position to see what limbs may be removed without cutting away too much wood, and, this done, the work of removing thin shoots that cross and rub each other may be performed with knife, secateurs, or the Standard Tree Pruner. If the thinning is performed by the combined efforts of a steady hand and a thoughtful brain there will be no merciless slashing and cutting to waste, but the head will be opened to let in the light and air, and reasonable space will be allowed between growths that previously rubbed and interlaced each other. Need I point to the good results? I think not, for they will be seen in the size and quality of the fruit later on, particularly if some attention is also paid to the roots. Poverty is more often the cause of

#### CANKERED TREES AND SCRUBBY FRUITS

than anything else, and orchard trees suffer sadly in this respect. When will owners of orchards realise that established trees may be manured with advantage in winter? Frequently when passing farm and other homesteads one may see streams of rich liquor trickling away to waste from heaps of manure. This liquor would spell new life and renewed vigour to the fruit trees in the orchard if it were poured over the roots, so there never need be any anxiety about what to do with the contents of sewage tanks at a season when it is not wanted for garden crops. The ideal orchard is not that in which rank grass grows up to the stems of the trees, nor that from which a stack of hay is annually obtained. What the trees rejoice in is a short green pasture fed off by sheep which supply manure, though calves and poultry may be given the run of the orchard with advantage.

On heavy soils, which are naturally lacking in lime, a dressing of this useful commodity may be occasionally given with advantage to both the fruit trees and the turf, and failing this I would suggest a surface-dressing of basic slag in the winter. It is a common practice to lime-wash the stems and lower limbs of orchard trees for the purpose of destroying moss growths and insect pests, and though it has the desired effect generally, whitened trees have a ghostly look. For this reason caustic alkali solution may be used instead, and it is safe to say there is no better winter wash for fruit trees. The solution may be prepared by dissolving  $\frac{1}{2}$  lb. of caustic soda and  $\frac{1}{2}$  lb. of pearl ash in five gallons of water along with a handful of soft soap, or it may be obtained ready prepared from any firm making a speciality of insecticides and horticultural sundries. It should be remembered that the solution is strongly caustic, and should therefore be kept off the hands and clothing. It may be applied at any time while the growth is dormant, either by means of a sprayer or with a stiff brush to the stems and lower branches of the trees.

G. H. HOLLINGWORTH.

## MISCELLANEOUS.

### FORMING WOODLAND RIDES.

WE have lately shown how to get rid of some of the worst of our now profitless underwoods, so often worn out, thin, and poor in effect; and now we take up a subject of scarcely less importance, namely, the tracing and making of simple rides through woods. These are necessary for shooting, as well as for the clearing of the woods, driving, hunting, and the pleasure of riding or walking in them, and they are often best dealt with in replanting worn-out underwoods. The older and more picturesque the woodland, the easier the task of making drives pleasant to the eye at all times as well as right for use, though it is not unusual to see many woods without rides of

any value. It is not a hard task to improve them, making them at first a little more open than is common, and cutting away here and there to bring into view good groups of trees, or any helpful incident such as a gully of Ferns. Native plants are often beautiful in masses near these rides, and their effect seen in any clear way in shade is as good as that given by any exotic plants. These are among the right places to have beautiful native plants that may be absent naturally in the district, such as Solomon's Seal, Lily of the Valley, and Willow Herb; also many of our hardy Ferns, introduced again to their home in moist spots in the woods, sorts such as the Royal Fern, robbed by the hawkers from the many spots in the home counties where it once graced the shade with its stately form. Groups of neglected native shrubs might be planted here and there, and native trees not often planted in the usual mixtures, such as the Aspen and Field Maple, may be brought into the wood-fold. In warm and sea-shore districts not often stricken by severe frost we may have groups of Pampas Grass, New Zealand Flax, and hardy Bamboo here and there, but generally through the land it is better to trust to good native things. And, if we go beyond these, let us take care that the shrubs are as hardy as any of our own bushes; it is easy to find them in the shape of hardy Azaleas and Rhododendrons, and the beautiful Mountain Laurel (*Kalmia*), where the soil is not against them. Woodland rides should be not less than 18 feet wide, and it would be no loss from a shooting or any other point of view to make them a few feet more; if a ditch must be made on either side to get rid of water it ought to be in addition to the 18 feet. Their surface should be of the things of the wood—Grass, Moss, dwarf Heather, Thymy turf, brown leaves—according to soil and elevation and other conditions. Among other reasons for this is the fact that such surfaces drink up and keep for use the water that falls, whereas if it falls on bare surfaces our drives and paths may become water-courses. In very hilly ground we may have to cut rides out of the hillside, and make our drive of shale or rough gravel, sand, or peat. In these, or on any surface where we cannot find a protecting carpet of vegetation of any kind, we may have to form little hollows skew-wise across the walk so as to throw the storm-water aside. Woodland drives should want no care beyond the annual "fagging" which the gamekeepers do to remove Briars and all interloping rank growth before shooting begins. But in woods of any beauty coming near the house it may be worth while to rough mow them now and then.

#### SUNNY SPOTS IN WOODS.

Shade is one of the summer charms of the woods; but in case the shade is too great for any of our plants or bushes we have a chance for sun-lovers in glades or open spaces, like those so often seen in natural forests. These are to be sought now and then in our woods for the sake of various things—game, sun, light and shade, and the variety of tree form which is often seen around such openings. The floor of these glades may be of turf, Fern, Ivy, or any mixed plants of the woods, and they give us also a good place for evergreen or other covert—Savin, dwarf Mountain Pine, Partridge Berry, Heaths, either Cornish Heath or the more vigorous forms of Heather, and, if we can spare them, brilliant bushes like Azaleas. Bushes needing sun and warmth might be grouped in such spots, and in districts where the cold does not strike hard, as in a great length of the shore-lands of our islands, other exotics might be tried. But they should be chosen with care, and only sought for some distinct quality. Incidents of the wood itself will often offer the best places for our sunny spots, and there might be small openings, too, in shade, suggested often by wood plants like Gerard's well-named Sturbwort (*Oxalis*) and Primroses. As trees take the place of underwood there is more need for our woodland sun-spots, and also for the drives through the wood being more open and airy, providing always that the too common way of thinning trees in a wood, so that each stands singly, be given up. This is a harmful, though well-established British practice, and against all profit or other good from woodland.

However, without any "fine" planting or attempt at the artistic as regards planting choice shrubs by studying carefully the lines of easiest access, grading in hilly districts, and the convenience of varied labours or pleasures of the woodland, we often gain a very beautiful result. I have made several miles of these rides during the past winter, and no labour has ever given me greater pleasure in the result. Where the ground is level the work consists of merely taking out old and often worn-out stubs. Where it is sloping it is a little more laborious, but even then not difficult. Where the woods have been a little neglected and are rather worn-out it is often easy to get as good a line where the ground is bare of trees as where it is well set with them, and thus avoid felling timber. Sometimes I crept under a great group of Oaks or Beech trees for the sake of their fine stems, and got a better effect than had I avoided them, besides using ground where nothing would grow. In some cases the result was so striking that parts of the woods, before unnoticed, became picturesque even in the opinion of artists, the airy foreground and the fine view along the clearances giving good pictures when the trees happen to come in the right way. Where there is much disturbance of the ground I sow mixed grass seeds as soon as possible afterwards, mainly in April, but also in the summer and autumn. As to game, the airy rides are a distinct improvement in every way, creatures of all sorts getting a chance to air and sun themselves in the clearances. The gamekeepers like it much better, and my woodman tells me that he always finds the best trees near the open rides. So that nothing is lost and everything is gained.—*Flora and Sylva* (November).

## NOTES FROM THE MARKETS.

### A FERN NURSERY.

MR. W. CULL of Lower Edmonton has long been known in the market as one of our most successful growers, Ferns being his speciality, but he only gives attention to the most useful market sorts. Mr. Cull first started at Tottenham, but was compelled for want of space to go further afield, and has now established quite a large nursery at Bury Street, the extreme north of Edmonton. The houses are all built on the most economic and convenient principles, and on a recent visit I found them well filled with Ferns in various stages of growth. *Asplenium biforme* is grown in large quantities, and Mr. Cull's variety is rather different to that found with most growers, being more compact in habit. Though one of the best in  $\frac{1}{2}$ -inch pots, it is even better when grown on to a larger size, and plants in 6-inch pots were a grand sight. *Asplenium Hilli* is also grown, but this is very slow growing; it is one of the best for 3-inch pots. *Pteris cretica major* is grown in larger quantities than any other Fern, and the demand fully warrants this. Mr. Cull says it seems impossible to get over-stocked, for it is a general favourite in all sizes, from small plants in  $\frac{1}{2}$ -inch pots up to large specimens in 6-inch pots, or even larger plants always sell well. *Pteris Wimsetti* is extensively grown, but it is chiefly in the small sizes that this is wanted, and *P. cretica cristata* is quite as much a favourite. *P. tremula*, *Phlebodium aureum*, and *Cyrtomium falcatum* are well grown. One large house was filled with *Asplenium Nidus*. A few years ago it would hardly have been expected that the Bird's-nest Fern would sell in such large quantities as it now does. *Adiantum elegans* is also largely grown; this is found more useful than *A. cuneatum*. I should add that from among seedlings of *Pteris Wimsetti* Mr. Cull has selected a distinct form which he has named *Wimsetti plumosum*; in this the multifid growths are finely cut. Certainly a distinct and pretty variety. *Aralia Sieboldi* is extensively and well grown, the plants being given sufficient room to ensure short sturdy growth. *Ficus repens* in hanging pots and on shelves was seen in large quantities.

COVENT GARDEN MARKET.

LAST week trade was very dull. On Saturday morning last many of the stands were empty, the growers not having made a fresh start since Christmas. There does not seem to be any sign of any immediate improvement in the trade for plants. There is a little demand for good flowering plants, but in Palms, Ferns, and other foliage there is scarcely any demand except for the small Ferns. Poinsettias are usually pretty well cleared up by Christmas, but they are holding out this season. On Saturday there were some of the best pot plants that I have seen. Cyclamens are more plentiful, but the best make very good prices. Mr. Orpwood of Uxbridge, who grows about 15,000, and sends a good many direct to the buyers from his nursery, tells me he has had a good demand for them this season. He was one of the first in the market with them, and continues to bring in well flowered plants. There are still some good Chrysanthemums coming in, also *Erica hymenalis* and *gracilis*. I have seen a few well flowered Rhododendrons, also Azaleas, mostly white, and Genistas, but these are not yet very full of flower. Tulips are very plentiful, but Hyacinths seem scarce this season. The Roman Hyacinths are very good. Some very fine plants of Begonia Turnford Hall are coming in. Gloire de Lorraine is not quite so plentiful as it was a few weeks ago, but there are some well flowered plants. In cut flowers Chrysanthemums are still plentiful, and the best blooms make good prices. Callas are also plentiful, and have gone down in price. *Lilium longiflorum* is also cheaper, but not over plentiful. Lily of the Valley is very good and the supply large, with a great fall in price. Good Roses are scarce, and make high prices. English Carnations are also scarce and sell well. One grower who is cutting about fifty dozen every day has most of them ordered beforehand, and of one variety, a good pink, all the blooms he can cut through the season are on order. Narcissus and Daffodils are now plentiful. A good many Polyanthus Narcissi are coming from the Scilly Islands. French flowers are plentiful again since the frost has gone. In the new French Market a big trade is done with the hawkers, but much of the best imported bloom is still sold in the ordinary flower market.

WOMEN AS GARDENERS.

WHEN at a recent meeting of gardeners to consider the formation of a national association, a letter was presented from a lady head gardener, in which it was requested that women holding such positions should be eligible as members, a ripple of laughter ran through the assemblage. It was by no means an ill-natured ripple, but it was one rather of amusement arising from the fact that the male gardener has not yet become familiar with women's efforts to be gardeners, or have yet learned to recognise their rights to obtain a livelihood in any honourable way.

In relation to work in competition with them women have done much in their own interest during the past ten years. They will do very much more during the next ten years, and probably by that time male gardeners will have become very familiar with the "lady" gardener. Did young men in gardens as a body—many do as individuals—but display that earnest determination to learn that is shown by women students, we should hear very much less complaint from "heads" than is now the case. Women not only display earnestness, but they are exceedingly industrious. They read, they attend lectures and classes, they work in glass houses, for instance as may be seen in such capital condition at Swanley and at Studley Castle, and they work in open weather outdoors.

They strive to make themselves familiar with real gardening elements, and to their credit be it said they grow, as their knowledge and experience progress, more alive to the fact that they are real workers, dropping all false pride and ignoring affectation or snobbishness. The young man in a garden who spends all his spare time in amusements or his thoughts even in working hours, on sports and pastimes, will presently find in these earnest women that he has beside him formidable competitors. It is just as well all gardeners should realise that the female gardener has come to stay. A. D.

THE FERN GARDEN.

DAVALLIA BULLATA MARIESI.

SOME years ago this beautiful Fern was first introduced from Japan. It was first known as *Mariesi*, pure and simple, and, though its deciduous nature would suggest its relationship to *bullata*, it is otherwise widely different; the rhizomes are slender, spreading more freely, and the fronds of a different substance. However, to whatever species it may belong, it is as

form of this beautiful *Davallia* that appeals most strongly to all lovers of Ferns. As mentioned before, these balls and other shapes have been very largely imported this season, and I may add that on a visit to Messrs. Carter and Co.'s nursery at Forest Hill early in the season I found a large house devoted entirely to them. An arrangement was made for hanging them one above the other, so that the most could be made of the space, and many of them were doing exceedingly well. It would be wrong to say all, for a few are sure to suffer from fungi germinated in transit and other causes.

It is, however, well to note that a large percentage do well after they arrive here, and they also further improve after the first year. There may be some who procure these Ferns while they have good fronds, who think them dead when they lose all the fronds in the autumn, but I would point out that if they are kept moderately dry for a short time and then watered again they will soon start to make new fronds, and often they will make larger fronds the following season. I would also like to point out that this Fern may be raised from spores in this country, and while in quite a small state it is very pretty; it makes one of the best for larger pots. I have seen excellent examples in 5-inch pots, the rhizomes spreading over and covering the pots, and the beautiful

DAVALLIA BULLATA MARIESI SHOWN IN VARIOUS CURIOUS FORMS.

*Mariesi*, that it is now so extensively imported from Japan. It was in the form of round balls that I first saw it, and this must be nearly twenty years ago. Since that time we have seen many importations of these balls, and also other arrangements made up in various fantastic styles—monkeys, frogs, birds, and even foxes, elephants, and other animals, yet, after all, it is the globular balls which are the most satisfactory. During the past season the importations have far exceeded anything I have previously known, and I may add that many of them offered for sale have been in a poor condition, and may prejudice some against what, when well grown, is one of the best Ferns we have.

Although those grown in the ball shape are the best, the other designs are interesting and find favour with many. I would point out that the substance they have to root into is meagre, consequently they require some care. While so many Ferns do well when exposed to more light and air than is generally given, these require a moist corner where the atmosphere is close and humid. Interesting as these various grotesque forms may be, it is the more natural

fronds radiating on every side. Seen at its best there is no prettier Fern in cultivation.

A. HEMSLEY.

A GARDEN IN SCOTLAND.

OSWALD HOUSE, EDINBURGH.

IN and around the city of Edinburgh there are many good private gardens, and it is known to most of those interested in horticulture that one of the best of these is that of Mr. J. Buchanan, at Oswald House, St. Oswald's Road. Its owner is a keen lover of flowers himself, and it is well known that the exhibits from his garden help much to maintain the high character of the private exhibits at the great Edinburgh shows, where his gardener, Mr. George Wood, is a frequent prize taker. The garden of Oswald House is within the city boundary, on the south side of the city, and looking towards the Blackford Hills. It occupies an area of about three acres and is surrounded by walls. While it is best known as an establishment where the Orchid takes a leading place, the garden of Oswald

House must not be considered as devoted to that flower alone, nor only confined to stove and greenhouse plants. When I visited it November was almost at its close, an unpleasant time for seeing the outdoor garden, but in spring and summer there are many charming features. The best types of vegetables are cultivated here. Fruit is also grown in considerable quantity, and the Apples are models of what such trees should be. The Apples which do best at Oswald House are, for dessert, King of the Pippies, Cellini, and Lord Derby; Cox's Orange Pippin not doing so well. For cooking, the favourites are Stirling Castle, Lord Suffield, and Ecklinville Seedling. Small fruits do well, and Raspberries, Currants, Gooseberries (Preston Seedling is the favourite Gooseberry), Strawberries (particularly Royal Sovereign, Garibaldi, and Black Prince) and the Japanese Wineberry are all successfully cultivated. Capital crops of Grapes are in the vineries, and some young vines are in readiness for contemplated renewals. Peaches do well also.

The less formal parts of the gardens are attractive with their well-kept turf, while in summer the beds are filled with suitable plants. The well-kept tennis lawn is converted into a skating pond in winter, and great care must be taken to keep it in such good order with its annual floodings. Although there was little in bloom in the borders, except a number of Chrysanthemums, of which many are cultivated outdoors, a large variety of the best spring, summer, and autumn hardy plants were seen, while the labels showed to some extent how rich in bulbous plants the place must be. Spring and summer Phloxes, Statice, Asters, Helianthus, Saxifrage, Sedums, Doronicums, Campanulas, Irises (bearded and Spanish), Anemones, Veronicas, hardy Orchids, Narcissi, Tulips, Crocuses, Zephyranthes candida, and many others testified to the diversified tastes of the owner of the garden.

The houses are very extensive and of the best construction. In the first range entered one observed the glowing flowers of Gerbera Jamesoni, Chrysanthemums, Fuchsias, Begonias, Primulas sinensis, obconica, floribunda, &c., Statice Bucheri, and others, and a varied collection of other plants. At rest were between 200 and 300 Hippeastrums in pots, many of them raised here, and comprising a large proportion of fragrant varieties. In the Melon house Tomatoes and Melons are grown extensively, but they are now occupied by a splendid lot of Caladiums, Codiaums (Crotons), Streptocarpus, &c. The Palm house is fully stocked with fine Palms, Ferns, Pandanus, &c. Among the finest specimen Ferns were fine ones of Davallia fijiensis, Tyermanni, and bullata, and a fine specimen of Aglaomorpha (Polypodium), meyenianum, and a magnificent piece of Microlepia (Davallia) hirta cristata. One cannot hope to treat of the numerous glass structures in detail, for, apart from the Chrysanthemums (nearly over), they are occupied by a delightfully varied lot of plants. Taking the names of some of these at random, one may name the crested Cyclamens, Camellias, the Guava, a splendid lot of Anthuriums, Nertera depressa, and a host of other stove and greenhouse plants, while the frames are full of those either to succeed the ones in flower or to await the advent of spring to be planted in the open.

The great speciality here is the Orchid, and only the pen of an expert could hope to do justice to the collection, which contains many fine sorts and specimens of great excellence. Mr. Buchanan's garden is noted for its plants of Nanodes Medusa, which are grown under cool treatment. It is hopeless to attempt to exhaust, or even to single out in a systematic way, the best of the Orchids here. A few names taken as they come may, however, give an idea of the representative character of the collection. Thus there are many of the best of the Orlontoglossums—crispum Edwardi, wilckeanum pallens, grande (a very fine type), bictonense, Pescatorei nevium, &c. Cypripediums are very numerous, and the splendid pans testified to the excellence of the culture; villosum aureum, leeanum, lawrenceanum, harrisianum, Ashburtoniae caudatum, Stonei (very fine), barbatum, Exul, a very fine form of spicerianum,

chamberlainianum, and many more called for admiration whether in or out of flower. Masdevallias were also fine. The pans of tovarensis were of great beauty—igneus, harryana, amabilis, bella, houtteana, and Chelsoni were among the others. Cattleyas are splendidly grown, among them being some fine plants and forms of labiata, and some splendid pieces of crispa buchaniana (a grand variety). The Dendrobiums were exceptionally well grown, and included fimbriatum (very good), nobile, thyrsiflorum, densiflorum, brymerianum, wardianum, Cassiope, and findlayanum. Cologynes were equally good, and I noted cristata, cristata alba, the Chatsworth variety, and the difficult gardneriana, which does well at Oswald House. There was a splendid lot of Lælias, among them being anceps rubra (exceedingly fine), purpurata, superbiens, pumila, &c. Vandas were well done also, and among the Sobralias was a particularly good S. macrantha. Then there were Angreacumburneum, Anguloa Clowesii, Staehopeas in several good forms, Dendrochilum glumaceum (Platylinis glumacea) in flower, Miltonias, among them being vexillaria rubella superba (certificated at one of the Edinburgh shows), Epidendrum prismatocarpum, Pleione (Cologyne) lagenaria (well flowered), Sophronitis grandiflora, Trichosma suavis, Trichopilia coccinea, Ada aurantiaca, Leptotes (Tetramicra) bicolor, Oncidiums, Cymbidiums, and many more.

The whole place is full of interest, and though the season was not the best for a visit, we hope to have the privilege of repeating it at a time when there is a fuller display of the now largely hidden floral wealth of Oswald House. S. A.

## KEW NOTES.

### INTERESTING PLANTS IN FLOWER.

#### Temperate House.

ACACIA GLAUDESCENS and Brachysema Drummondii.

#### Range.

Anthericum triflorum, Columnea sanguinea, Costus fissiligulatus, Dædalacanthus macrophyllus, Lachenalia pendula, and Scilla peruviana.

#### Greenhouse.

Coleus thyrsoides, Hibbertia dentata, Loropectalum chinense, Peristrophe speciosa, Prunus japonica fl.-pl., Senecio grandifolius, S. macroglossus, S. tussilaginis, and Sparmannia africana.

#### Orchid Houses.

Arides Roebelenii, Bulbophyllum auricomum, Catasetum labiatum, Cologyne graminifolia, Cryptostylis Arachnites, Cypripedium Charlesworthii, C. deedmannianum, C. fitchianum, C. haynaldianum, C. nitens, and others, Epidendrum ciliare, E. elegans, E. fragrans, E. variegatum, and others, Erica stricta, Habenaria tridactylites, Lælia alba, L. anceps, L. gouldiana, Lælio-Cattleya Amelia, Masdevallia ignea, M. tovarensis, Odontoglossum pardinum, O. Pescatorei, Phalænopsis stuartiana, Saccolabium giganteum, Seraphyta multiflora, and Tainia penangiana.

#### Alpine House.

Colchicum libanoticum, C. luteum, Crocus biflorus var. Adami, C. Imperati, C. lævigatus var. Fontenayi, Cyclamen Atkinsii, C. Coum, C. ibericum, Galanthus byzantinus, G. Elwesii var. unguiculatus, Ionopsidium acaule, Iris Histrio, and I. Vartani.

#### Herbaceous Ground and Rock Garden.

Crocus caspius, C. Korolkowi, Helleborus caucasicus, H. orientalis, Iberis gibraltaria, and Iris unguicularis.

#### Arboretum.

Chimonanthus fragrans var. grandiflorus, Clematis calycina, Erica mediterranea var. hybrida, Garrya elliptica, Hamamelis arborea, and H. mollis.

**Messrs. Richard Smith and Co.'s Centenary.**—The nursery business of Messrs. Richard Smith and Co., Worcester, was established in 1804 by the grandfather of the present proprietor, so that this year the firm will celebrate their

centenary. During this long period Messrs. Richard Smith have supplied, as they still supply, everything for the garden, whether seeds, bulbs, or nursery stock. They have had the honour of supplying the King, the late Queen Victoria, and various members of our own and other Royal Families, as well as enthusiastic amateurs throughout the United Kingdom and abroad. Their long and successful record must be very gratifying to Messrs. Richard Smith and Co.

**Mistletoe.**—It is difficult to see by what exact process of reasoning Mistletoe (*Viscum album*) has come to be regarded as poisonous by the vulgar. Botany books describe the fruit as "inferior" but succulent, and we know that birds, especially the mistle-thrush, eat it and convey the undigested seed to the trunks of trees to which its viscid coating enables it to adhere. Writers, from Paracelsus down to quite recent times, have been loud in their praises of Mistletoe as a cure for epilepsy, and as lately as 1881 Dr. R. Park, writing in the *Practitioner*, describes a mining district in the Forest of Dean where heart troubles were habitually treated with a certain tincture of Mistletoe, which was handed on to him among medicine bottles found in a rural surgery. This proved a good substitute for Digitalis. At the beginning of the eighteenth century Colbatch published a work upon Mistletoe which ran into many editions. He describes a drug made from the plant as "a most wonderful specific remedy" for convulsions, and as late as 1806, if not later, the same drug is prescribed most confidently by a certain Dr. Henry Fraser in cases of epileptic seizure. Going back to the days of Pliny we find that philosopher describing the *Viscum album* as an antidote to poison, and a remedy for sterility. His, too, is the classic description of the plucking of the Mistletoe by the Druids. At a later period, but still long before medicine had arrived even at the "signaturist" stage, Mistletoe is found playing a great part in the *Völuspá* and other Scandinavian sagas. It was with a sprig of the plant, or an arrow made of the stalk of the plant, that the blind and somewhat dull-witted god Hodür was induced by Loki, the evil principle, to have his fling, in a literal sense, at Balder, the Daylight, or good principle. Myth represents Balder as being killed outright by the Mistletoe, a little plant growing on the eastward slopes of Asgard, and the sole thing among minerals, plants and poisons, as well as among gods and men, that had not promised Freya to be harmless if used against her son Balder. Within this myth of the German forests there are doubtless other myths, but it is to this one, perhaps, that the Mistletoe owes its character as a poisoner, a remedy in cases of "soul disease"—for it was thus that epilepsy was regarded—and as a presider over chartered liberties between the sexes now symbolised by kissing.—*The Lancet*.

**Stenotaphrum glabrum.**—In THE GARDEN of the 9th inst. a note appears on the usefulness of some Grasses for indoor decoration, the particular kind there mentioned being *Paspalum elegans*. A Grass that I had long known before the full extent of its merits was recognised is *Stenotaphrum glabrum*, which is suitable for a hanging basket, and in this way there was, some seven or eight years ago, in the reptile house at the Zoological Gardens a most effective specimen, for a large basket was filled with it alone, and the long, thong-like stolons with their tufts of leaves disposed at regular intervals hung down for 4 feet or 5 feet. Since then I have employed it in a similar manner, and also as an edging to stages, for it will thrive in a very little rooting medium, and is not injured by passers by. Under favourable conditions it is of very rapid growth; the long creeping stolons, rooting at every node, from where a tuft of leaves is produced, soon cover a considerable distance. It is in many tropical countries used to form a kind of turf. There is a variety in which some of the leaves are variegated, but this is very liable to revert to the normal form. Besides the above name it is sometimes known as *Stenotaphrum americanum*. Another useful Grass is *Opismenus Burmannii*, which is generally met with in gardens as *Panicum variegatum*.—T.

# THE GARDEN

No. 1679.—Vol. LXV.]

[JANUARY 23, 1904.]

## THE FAILURE OF FRUIT BLOOM.

**M**ANY weeks must elapse before the fruit trees flower, but it may, as was the case last year, be less distant than is generally the case, because at the time of writing the winter is comparatively spring-like. If no severe weather occurs soon the flowering of fruit trees will be unduly accelerated. Should that be so we may not have to wait long after all before Peaches and Apricots, Plums and Pears will be in bloom. The great failure of the flowers last year produced a general impression that this was due to the cold, unless weather which prevailed at the time of flowering, accompanied with sharp frosts, and an early season. But some keen observers attributed the failure of the bloom to set well to the lack of due warmth the previous summer and autumn, and for this reason the organs of fertility were imperfectly developed and pollen was defective.

If that really were the case, it is not at all difficult to understand how it was that the bloom failed on all trees alike, with few exceptions. If we saw Apples, Pears, Plums, Cherries, and even wall trees either entire failures or producing miserable crops, at least here and there amongst Apple trees, some old ones, or those comparatively stunted, carried good crops. Those exceptions, it was assumed, were due to the fact that their efforts during the season were less concentrated on wood production and more on spur or bloom bud production, hence whilst many other fruit trees were barren, those with perfectly developed buds and ample pollen were fruitful. Certainly the bloom on them had to withstand the same evil climatic influences that all other tree flowers had to endure, yet that set, whilst the other failed.

There seems to be a prospect that trees will produce an abundant bloom in the spring. Probably when expanded there will be optimistic anticipations indulged in as to its ultimate product. If there should be a really fruitful result the product will be indeed a great boon, full of goodness to us all. But if another failure should result (from which misfortune we trust to be saved), will the reasons for such failure be rightly ascribed? Would it be possible for such a body as the Royal Horticultural Society's scientific committee to take fruit tree bloom under observation, to examine it microscopically, and thus

ascertain whether the organs of fertility are normal, and whether pollen grains be produced in sufficient quantity to produce fertility? Of course, it is well known that some varieties produce pollen less freely than others, hence the advantage there is in having several varieties of Apples, Pears, Plums, &c., grown close to each other that pollen may be transferred. But that fact would also render it needful to conduct observations over many varieties and also over a wide area. Where pollen is in moderate quantity, should the blooming season be favourable, a very good set may result. But if pollen be weak and a cold, gloomy, frosty time prevails, there seems to be little prospect of a satisfactory set. There is yet time also on such trees as Apples and Pears, where there is a promise of a heavy bloom, to materially thin spurs or buds on some and thus note how far a reduction of the bloom helped fertility or otherwise. So keen an observer as the late Mr. A. F. Barron used to deprecate a heavy tree bloom, on the ground that it was too exhaustive to be fertile. Assuming that bloom next season is heavy and that it is fairly good also, no doubt its fertility will be greatly helped by the heavy rainfall of the past year, even though other climatic conditions to promote maturity have not been favourable.

## THE WILD PINKS.

(Continued from page 25.)

**D. CHINENSIS** (Chinese Pink).—This well-known plant is a native of Central Asia, having been introduced from China nearly 200 years ago. About 1½ feet high, of freely branching habit, the fragrant reddish coloured flowers are produced in great profusion in summer. This species has given rise to a race of beautiful and very effective border plants with a considerable range of colour. The best known is probably *D. Heddewigi*, the Japanese variety, a strain of dwarf compact and handsome forms. There is also a section with more deeply lacinated petals. *A. c. var. dentosus*, the Amur Pink, is a distinct and pretty dwarf form, with violet-lilac flowers 1 inch in diameter, toothed margins and dark spots near the base of the petals, giving the flower the appearance of having a dark eye. Found on the coast of Manchuria.

**D. CILIATUS**.—A plant with a shrubby tendency, found in Italy; of tufted habit and having ciliated leaves. The flowers are white with almost entire beardless petals.

**D. DELTOIDES** (the Maiden Pink).—Another of our native Pinks, found in dry, gravelly pastures in various districts. The wild plant is of rather loose habit, with short blunt-pointed leaves on the barren stems, and longer narrower

leaves on the flowering stems. It will grow almost anywhere, improving in good soil, and producing its bright pink spotted flowers freely. *D. d. var. glauca* is a form which is found on Arthur's seat, near Edinburgh, with white flowers having a pink eye. Distributed over Europe with the exception of the northern part.

**D. FRAGRANS**.—A Caucasian species of lax, tufted habit, with flower stems 9 inches to 12 inches high; mostly single flowered, but sometimes attended with a second one on a short axillary peduncle. The flowers are white, with finely toothed petals, blooming in July.

**D. FREYNI**.—Closely allied to *D. glacialis*, to which species it is reduced as a variety by some authorities. This is one of the smallest and most compact plants in the genus. With slightly glaucous leaves, and purple flowers three-quarters of an inch in diameter, borne singly on very short stems. There is also a variety with pale flowers. A native of Hungary and Bosnia, it was introduced in 1892.

**D. GLACIALIS** (Glacier Pink).—A very small tufted perennial with grass-like leaves. This rare species is found on the high granitic mountains of Central Europe. The small reddish purple flowers with dentate petals are scentless and solitary, on very short stems only 1 inch to 3 inches high. Frequently a long lived plant in cultivation, its chief enemies are slugs, which are fond of it, and against whose attacks it must be carefully guarded. It will thrive in sandy peat to which may be added a proportion of granite chippings. *D. g. var. gelidus*, from the Transylvanian Alps, is now given specific rank in Williams' monograph.

**D. LEPTOPETALUS**.—This plant, which is more curious than beautiful, is remarkable for its long, narrow white petals. The flowers are in twos and threes on slender stems, sometimes over a foot in length. A native of the Caucasus, from whence it was introduced in 1814. It flowers in July.

**D. LONGICAULIS**.—From Mount Amaro in Italy, this plant is of tufted habit, with solitary rose-coloured flowers on slender stems, 9 inches to 12 inches high in summer.

**D. MASMENEUS**.—Named after one of its habitats, Masmeneu-dagh in Kurdistan, this species is also found in the alpine region of the mountains of Cappadocia. A pleasing plant, of somewhat lax habit, the flowers are usually in loose cymes on short peduncles; the dentate petals are rose-coloured above and yellowish underneath.

**D. MICROLEPIS**.—A distinct little alpine, very dwarf and tufted in growth, with small rose-coloured flowers, solitary, on stems 1 inch to 2 inches high, flowering in August; it is a native of Eastern Europe, growing on the high alpine rocks in Transylvania and Macedonia. There is also a white-flowered variety in cultivation.

**D. NEGLECTUS**.—This charming species is referred to *glacialis* by some authorities, and is made a variety of that species by Williams in his monograph. It is, however, a much taller

plant, with stems 6 inches high, with tufts of narrower and more pointed leaves. These are more inclined to be glaucous than those of the Glacier Pink, and the deep rose-coloured flowers are frequently borne two on each stem. A native of the high alpine regions of the Swiss and Italian Alps, it was introduced in 1869, and is one of the prettiest of our rock plants, succeeding in an open situation in stony soil or in a crevice. W. IRVING.

(To be continued.)

## NOTES OF THE WEEK.

### FORTHCOMING EVENTS.

January 26.—Royal Horticultural Society's Drill Hall Meeting, 12 noon.

February 2.—National Amateur Gardeners' Association Meeting.

February 6.—Société Française d'Horticulture Meeting.

February 8.—United Horticultural Benefit and Provident Society Committee Meeting.

February 9.—Royal Horticultural Society's Drill Hall Meeting; Horticultural Club Annual Meeting, 5 p.m., Annual Dinner, 6 p.m. Sir John Llewelyn, Bart., chairman of the club, will preside.

February 10.—East Anglian Horticultural Club Meeting.

February 12.—Royal Gardeners' Orphan Fund Annual General Meeting.

February 23.—Royal Horticultural Society's Drill Hall Meeting, 12 noon.

**Royal Horticultural Society.**—The next fruit and flower show of this society will be held on Tuesday next in the Drill Hall, Buckingham Gate, Westminster, 1—4 p.m. A lecture on "Oranges" will be given by Mr. H. Somers Rivers at three o'clock. At a general meeting of the society, held on Tuesday, the 5th inst., fifty-three new Fellows were elected.

**Gardeners' Royal Benevolent Institution.**—The festival dinner of this institution will be held at the Hotel Metropole, Whitehall Rooms, on June 28 next, when the treasurer, Mr. Harry Veitch, will preside.

**National Rose Society: Fixtures for 1904.**—Metropolitan show, Inner Temple Gardens, London, E.C., Wednesday, July 6; autumn show, Horticultural Hall, Vincent Square, London, S.W., Tuesday, September 20; annual dinner, Thursday, December 8, Hotel Windsor, Victoria Street, S.W.

**Gardeners' Royal Benevolent Institution (Liverpool Auxiliary).**—The first annual meeting of this institution was held at the Golden Lion Hotel on the 12th inst., Mr. C. A. Young in the chair. The secretary's report proved in every way a satisfactory one. The total number of life members and subscribers is twenty-two, in addition to many who contribute direct to the parent body. The total amount paid to Mr. Harry J. Veitch, the treasurer, is £103 9s., with a small balance in favour of the local branch. A smoking concert was held under the auspices of the society, when Mr. R. J. Harvey Gibson, M.A., F.L.S., presided. This proved an excellent medium for making known the advantages of this institution. Votes of thanks were accorded to Messrs. R. P. Ker and Sons, Thomas Davies and Co., and C. A. Young for their generous assistance in providing the floral decorations on that occasion. The following officials were unanimously re-elected to their respective positions: Chairman, Mr. C. A. Young; treasurer, Mr. A. J. Crippin; and secretary, Mr. R. G. Waterman, Woolton. Arrangements are in progress for the third concert, to be held on February 13, when W. W. Rutherford, Esq., M.P., has kindly consented to preside. It is to be hoped he will be well supported, so that the institution may derive substantial benefit.

**Kew gardeners' social gathering.**—The seventh annual social gathering of the young gardeners in the Royal Gardens, Kew, and their

friends was held on Friday, the 15th inst., at the Boat House, Kew, and proved a great success. The room was tastefully decorated with Palms, evergreens, &c., and a programme of thirty items included an excellent selection of music and dances. Over 150 persons were present, many of them being old "Kewites."

**Mr. John Burns**, who for many years has been superintendent of the Leicester parks, resigns his position at the end of this month. To the numerous exhibitors, judges, and other officials annually attending the Leicester flower show Mr. Burns has long been a familiar personality, and a cheery welcome to visitors could always be depended upon from him.

For the past twenty-two years Mr. Burns has had charge of the public parks, open spaces, and street planting under the Corporation of the Borough of Leicester, and he has now placed his resignation in the hands of the parks committee, which is to take effect at the end of this month. During Mr. Burns' term of service he has laid out under the municipality some 500 acres of parks and open spaces, and in various parts of the town there are to be found commodious parks admirably planted and maintained, which are greatly appreciated by the Leicester folk, and to which they flock in favourable weather. A pleasing feature is the gymnasium attached to each park, the children being particularly provided for. The Abbey Park—the largest and most popular of the Leicester parks, in which is the residence of the curator—has been the special pride of Mr. Burns, the large glass conservatory and other houses being filled with many large specimen plants. The Abbey Park flower show, which is held on the first Tuesday in August, originated with Mr. Burns, and he has been its superintendent, carrying out the arrangements with the assistance of a competent staff. It is now a great Midland gathering. Many exhibitors and judges have a grateful remembrance of the kind hospitality and attention they have always received from Mr. Burns. In all probability Mr. Burns will reside in the North.—R. D.

**Potatoes in 1903.**—The following statement from the Agricultural Returns of Great Britain for 1903 shows the estimated total produce and yield per acre in Great Britain in the year 1903, with comparisons for 1902, and the average yield per acre of the ten years 1893-1902:

Crops.	Estimated Total Produce.		Average.	
	1903. Tons.	1902. Tons.	1903. Acres.	1902. Acres.
England .....	2,041,023 ..	2,225,569 ..	402,725 ..	412,739 ..
Wales .....	131,846 ..	155,508 ..	30,197 ..	31,446 ..
Scotland .....	740,844 ..	813,111 ..	131,364 ..	129,095 ..
Great Britain ...	2,913,713 ..	3,194,188 ..	564,286 ..	573,880 ..

Crops.	Average Estimated Yield per Acre.		Average of the Ten Years.

Great Britain ...	5.16 .....	5.57 .....	5.89 .....	5.89 .....

**The late Mr. J. C. Fidler.**—The short time which has elapsed since the sudden death of Mr. J. C. Fidler of Caversham has enabled the people there and in Reading, where he was so well known, to realise more vividly the loss the district has sustained. He was a man of wonderful foresight and great ideas, and was the originator of many schemes either projected or in course of reaching a practical completion. Mr. Fidler's first building scheme was the demolition of the tumble-down property in Friar Street and the east side of West Street, and the substitution of the handsome range of buildings now standing there. He practically rebuilt the whole of the east side of West Street, round to the present commodious premises of his firm. He built the whole of Thames Terrace, Caversham. He constructed Queen Victoria Street, a thoroughfare 350 feet in length, connecting Friar Street with Broad Street. Mr. Fidler made roads and erected villas, a considerable number being at present in the course of construction. Another notable venture was the

purchase of Prospect Park from Major Liebenrood. Mr. Fidler immediately offered to sell part of it to the town. The Corporation at first declined, but subsequently accepted the offer, Mr. Fidler himself contributing £1,000 towards the cost. At the time of his fatal illness Mr. Fidler had several great schemes in his mind.

**The late Mr. William Horne.**—The interment of Mr. William Horne, senior partner in the firm of Messrs. William Horne and Sons, took place at Cliffe amid every manifestation of respect and sympathy. The deceased gentleman was fifty-four years of age, and had been for many years one of the churchwardens of the parish. Death was due to heart disease, after an illness of some weeks duration. In July last, when hurrying to catch a train, he was seized with heart trouble, and, although he recovered sufficiently to get about again and attend to his business at Rochester, Maidstone, and other markets of the county, he suffered considerably, and his death did not come altogether as a surprise to his relatives and intimate friends, although he was of robust appearance.

**A Nature study exhibition.**—Those who are endeavouring to stimulate interest in Nature study will learn with satisfaction that the Bath and West and Southern Counties Society has arranged to hold a Nature study exhibition in connexion with its annual meeting at Swansea in May next. The remarkable interest—as shown by the number of exhibits and the attendance of visitors—manifested in a similar exhibition held by the society for the first time at Bristol last year justifies a belief that the annual migratory show might with advantage be utilised for bringing such teaching as goes direct to Nature for inspiration under the notice of agriculturists and others. The society, therefore, through its Nature study committee, consisting of the president of the society (Lord Windsor), the Marquis of Bath, the Right Hon. H. Hobhouse, M.P., Sir C. T. D. Acland, and Messrs. H. M. Cundall, F.S.A., F. G. Farwell, A. G. Legard, H.M.I., J. C. Medd, M.A., G. H. Morrell, M.P., and N. Story-Maskelyne, F.R.S., invites educational authorities and institutions to contribute, for exhibition, collections, models, appliances, &c., illustrative of the subject in question, the desire being to render the exhibition as representative as possible.

**Hydrocyanic gas as an insect destroyer.**—Experiments of an interesting character were made recently at Messrs. Lodd's Nurseries, Swanley Junction, in the demonstration of the new process of cyaniding by hydrocyanic acid gas in glass houses. The experiments were performed in the presence of about twenty-four growers. It is claimed that the gas will destroy all insect and vermin pests to which flowers and plants of any kind grown under glass are subject. At the same time it has to be borne in mind that the operation of cyaniding must be very carefully performed, or the gas will kill the men as well as the insects. Other experiments are to be made. Those referred to were fairly successful.

**"The Woman's Agricultural Times,"** which is edited by the Countess of Warwick, will be reissued in the form of a quarterly magazine, price 6d. The *Woman's Agricultural Times* was started in June, 1899, as a penny monthly, and has thus completed four volumes. Although it is primarily the official organ of the Lady Warwick Agricultural Association for Women and of the Lady Warwick College, its range is by no means confined to this area, as it has dealt with almost all matters connected with the lighter branches of agriculture, and with rural industries, and, in a word, with anything relating to country life. Its aim has been to be of practical use to those who are trying to solve the problem of "Back to the Land." This journal will be published in January, April, July, and October. The Agricultural Association and the *Woman's Agricultural Times* are to be formed into a co-operative society, the required capital being £250. The prospectus will be printed in the first number. Among the contributors to the January issue are the Countess of Warwick and Lady Algernon Gordon-Lennox.

**Jacobinia coccinea.**—Although introduced to Kew from South America as long ago as 1770, outside botanical gardens this is a little known plant. Propagated from cuttings in spring, it requires warm greenhouse treatment till in flower, when it may be removed to a cooler house. It is advisable not to stop the plants more than once, as the more shoots a plant carries the smaller will be the terminal scarlet spikes in comparison. Several plants were exhibited by Messrs. Veitch, of Chelsea, at the Drill Hall on the 5th inst.—A. O.

**Felling trees by electricity.**—Experiments that have just been made in tree felling by electricity in various forests in France have proved completely successful. A platinum wire, brought to white heat by means of an electric current, takes the place of the saw. By this method the tree is cut through more easily and more rapidly than by the old process. The sawing is avoided, and the slight burning produced by the hot wire acts as a preservative of the wood. This new method, says *Le Jardin*, takes far less time than the old one.

**Senecio grandifolius.**—This striking plant has been in flower in the greenhouse, Kew, for the past five or six weeks; the bold, deep green leaves, over a foot in length, are surmounted by a corymbose inflorescence of yellow flowers 1 foot to 1½ feet across. Larger heads of flower are obtained from cuttings than from old plants. Inserted singly in small pots in a close propagating frame in February or March, and potted on as required without stopping, plants 3 feet to 4 feet high can easily be grown in one season. They may be placed outside in summer if the weather is favourable, but during such a summer as experienced last year they are best grown inside. It is also known under the name of *S. Ghiesbreghtii*.—A. OSBORN.

**Clematis calycina.**—The value of a plant can only rightly be tested when it is seen in the position where its distinct character can be displayed to the best advantage. Somewhat lukewarm praise was measured out lately to this evergreen Clematis, and very justly so, when it is grown as a pillar plant, for which it is not well suited. Perhaps one might even think twice before giving it a choice position on a wall, in spite of its beautiful foliage, for its flowers, though pretty and dainty, are not showy. But an echo of memory of long ago brings back to my mind this Clematis as it was grown in a Devonshire garden, on the low balustrade of a flag-paved terrace leading to steps, and it would have been hard to find a prettier garden picture. It may safely be said that in such a position or perhaps scrambling over a low, dry wall, it would not disappoint the most fastidious taste. It is not so tender as might be supposed, and may be grown anywhere south of London in sheltered spots. I can well remember the delight, on a winter's morning, of gathering the pale, freckled flowers which accord so well with the finely-cut bronzed leaves. The foliage, moreover, is particularly valuable for cutting to mix with *Anemone fulgens* or other early spring flowers. *C. cirrhosa* is often mistaken for *C. calycina*, for both are met with occasionally under the synonym of *C. balearica*, but though the flowers are not dissimilar, the foliage of *C. cirrhosa* is quite distinct in texture and colouring and has not the same value.

**Jacobinia chrysocephala.**—It is remarkable that a plant so conspicuously ornamental as the golden-crowned *Jacobinia* should not have found its way long before now into public regard—for once the high-sounding name is no misnomer. The fine group in flower, exhibited by Messrs. James Veitch, at the Drill Hall, on Tuesday, the 5th inst., will do more to call attention to its good qualities than many paragraphs in horticultural journals, though it has been commented upon several times in the pages of *THE GARDEN* and others with well-merited appreciation. It cannot be called a new plant, since it was first introduced from Mexico more than thirty years ago, but practically it was reintroduced only last year. This golden-crowned *Jacobinia* would be valuable for the greenhouse at any season, but the fact of its being winter flowering makes it tenfold more precious. On making its acquaintance for the first time one experiences a new sensation. It will

light up a cool greenhouse—the Cape house at Kew for example—on a dull November day with a glow of brightness almost dazzling, and quite inspiring at that dead season, while it continues in full beauty for many weeks, as is evident from its being exhibited now in the early days of the new year. The dark green, strongly-nerved leaves form an admirable background for the brilliant coronals of flowers. Like most square-stemmed plants, it is easily raised from cuttings, and as there is no special cultural difficulty to be overcome, no reason exists why this fine plant should not become even more popular and widely grown than its near relative the carmine-pink *J. magnifica carnea*, an old favourite, which, by the way, in recent years has run through several changes of name from *Justicia* and *Cyrtanthera* to the present one of *Jacobinia*, where we may hope both plants will now be allowed to rest.—K. L. D.

**Chrysanthemum W. H. Lincoln.**—This is still one of the best late Chrysanthemums. For some reason or other many of the recognised late sorts have been much earlier than usual. Probably this is due to the soft, unripened condition of the growth. *W. H. Lincoln* is an exceptionally good yellow. It is now approaching its best with us, and will be very useful till the end of January. It is not always that this variety can be relied upon, as, unless it is well grown, it has a tendency to produce deformed buds, which fail to open during the dull months of December and January. Golden Gem has been splendid, but unfortunately much earlier than usual, and its flowering period is fast approaching the close. *Lady Canning* is well up to its usual high standard, and is a worthy companion to *W. H. Lincoln*.—E. HARRISS.

**Missouri Botanic Garden.**—In accordance with the intention of its founder, the trustees of this garden offer theoretical and practical instruction for young men desirous of becoming gardeners. It is not intended that many persons shall be trained at the same time, nor that the instruction so planned shall duplicate the excellent courses in agriculture now offered by the numerous State colleges of the country, but that it shall be quite distinct, and limited to what is thought to be necessary for training practical gardeners. Six scholarships are offered, and are held for four years. Pupils, in addition to those holding scholarships, are also admitted to the garden at a charge of £5 per year for tuition.

**Gardeners' Improvement Society in India.**—Exactly a year ago several correspondents asked us to support a suggestion for the establishment in India of a Gardeners' Mutual Improvement Society. Personally we have much sympathy with such a movement, and should like to see it come to fruition. We are led to a consideration of the subject again from a letter we have received from an enthusiastic amateur gardener, urging us to ventilate the question again. We do so with pleasure, and quote what we wrote on the subject last year, in the hope that something practical will result. We wrote: "We have received two written expressions of opinion from Kew men on this subject; one of these is from Mr. A. C. Hartless, of Mungpa, who says: 'I am glad to see your article on a Gardeners' Mutual Improvement Society for India. Some time ago I was in correspondence with Mr. Gollan on this very subject, and he agreed with me that it was desirable; but owing to the almost impossible probability of our ever meeting together, we could not then see our way to doing anything further. Whatever society is formed it will be pre-eminently a corresponding one.' The more that gardening spreads in India the better for the profession, whether gardeners or nurserymen—especially nurserymen. We have had an interview with the Curator of the Royal Botanic Gardens, Calcutta, on this subject. He said his official duties did not permit him to take any leading part in the scheme, but he would be glad to give advice in the matter; he was not antagonistic to the measure."—*Indian Planting and Gardening*.

**Peristrophe speciosa.**—Belonging to the natural order Acanthaceae, this plant, according to the *Botanical Magazine*, t. 2722, where it is figured under the name of *Justicia speciosa*, is one of the greatest adornments of the interior of the

forests of Bengal. Of easy culture, it is certainly a most useful plant for greenhouse decoration during the winter months. Individually, the flowers are small, but this is more than compensated for by the freeness with which they are produced. The tube of the corolla is purplish in colour, the two lips being several shades deeper. Propagated by cuttings in spring, they should be pinched several times to form bushy plants; 6-inch pots will be large enough the first year. Should larger plants be required, old ones may be cut back after flowering, water partially withheld for a month, then started into growth in a warm house and potted into 8-inch pots. Occasional doses of weak liquid manure are very beneficial when the pots are full of roots. *Abutilon Savitzi* dotted here and there adds greatly to the effect of a group of this plant.—A. O.

**Abutilon Savitzi.**—This is a most useful and desirable plant to grow. I was much struck with it in a bed last season, associated with *Lobelia Queen Victoria*, with a carpeting of *Gazania splendens*, the whole making a very striking combination. Recently it was the predominant feature in the decoration of a large dinner table, and I do not think I have ever seen it to better advantage. The pink *Begonia Gloire de Lorraine* was sparingly used with it, just sufficient to add a little colour, but not enough to detract appreciably from the beauty of the *Abutilon*. Under artificial light the delicate variegated colouring of this lovely plant is greatly enhanced. It is easily propagated, and may be grown in quite tiny pots, which makes it very adaptable for decorative work.—E. HARRISS.

## THE FLOWER GARDEN.

### SELECTION OF SWEET PEAS.

THE following selection of Sweet Peas will be useful to those who want varieties for the spring sowing. These lists have been prepared under the auspices of the National Sweet Pea Society, and the following information is taken from the annual report for 1903. We may add to these the beautiful pink variety, Countess Spencer, which has been so well spoken of recently in *THE GARDEN*.

"In the classification list the number of votes recorded for a variety was taken to represent the value of that variety in its particular class, and, no doubt, this was a reasonable and also a pretty correct assumption. But the committee could hardly have expected that both the audits of the 1903 exhibition would show how remarkably correct the classification list—the first of its kind—is. The following colour list will explain the whole matter more readily than any words: In the first column are the nineteen colour classes; in the second column is shown the variety gaining the highest position in each class in the classification list; the third column indicates which variety of the same class occupied the highest position in the general audit; and the fourth column shows the premier variety of each class as indicated by the audit of first prize collections. Among pinks, Love has displaced *Prima Donna*, and *Gorgeous* has had to give place in the orange shades class to the all-conquering *Miss Willmott*. *Lottie Eckford* is equalled by *Maid of Honour* in the fourth column for *Picotee-edged*, and similarly *Jeannie Gordon* shares the honours with *Triumph* as the premier bicolor. *Dorothy Eckford*, as was anticipated, has surpassed *Blanche Burpee* as a white; the Hon. Mrs. Kenyon has ousted *Queen Victoria* from first place among the yellow and buff shades; and *Othello* has been passed over in favour of *Black Knight*. The new *Gracie Greenwood* takes the lead of *Lottie Hutchins* in the first prize audit, and as it is well up the list in the general audit it bids fair to lead the American variety next season, when it will be more widely grown. *George Gordon* has asserted itself as the best Magenta Sweet Pea, declining even the honour of being equal first with *Captivation* as indicated by the classification list. Thirteen of the varieties hold the highest position in their respective colour classes in all three lists,

but two of these have been rivals for first place in the affections of the leading competitors. This proves, if it proves anything at all, that the first work of the society in this direction was well conceived and well carried out, and suggests that quite apart from its usefulness as the provider of an attractive flower show, the society has claims upon the support of all who love and cultivate this most fragrant, popular, and beautiful of annual flowers.

In the audit of first prize collections there are forty-six varieties exhibited two or more times, and as in the majority of gardens no larger number of varieties is annually grown, a comparison between these forty-six and the first forty-six in the general audit may prove interesting and instructive. A glance at the two audits will show that thirty-eight of the varieties are found among the first forty-six

in both classes, although their positions may be considerably different. The eight varieties which are in the first forty-six of the first prize audit, but not in the general audit, are Agnes Johnson, Maid of Honour, Mrs. Eckford, Dainty, Duke of Clarence, Lord Kenyon, Monarch, and Mrs. W. P. Wright, while the eight varieties that are found among the first forty-six in the general audit, but are absent from the first prize audit, are Mars, Mrs. Joseph Chamberlain, Gorgeous, Blanche Burpee, Queen Victoria, Mrs. Dugdale, Hon. F. Bouverie, and Venus. Curiously enough, neither Mrs. Dugdale nor Venus was shown in a first prize collection, and, on the other hand, Katherine Tracy, Lemon Queen, and Modesty, which were only once shown in the entire competition, each appeared in first prize stands."

COLOUR LIST.

CLASSIFICATION OF SWEET PEAS.

By MR. HUGH ALDERSEY, ALDERSEY HALL, CHESTER.

I.—SELFS.

White.—Dorothy Eckford, Sadie Burpee, Blanche Burpee, and Emily Henderson.  
 Blush.—Duchess of Sutherland and Countess of Aberdeen.  
 Cream.—Mrs. Fitzgerald, Lottie Hutchins, and Gracie Greenwood.  
 Yellow.—Hon. Mrs. Edw. Kenyon, Queen Victoria, Lady M. Ormsby-Gore, and Mrs. Eckford.  
 Pink.—Lovely, Hon. F. Bouverie, and Prima Donna.  
 Rose.—Prince of Wales, Lord Rosebery, and Mrs. Dugdale.  
 Bright Rose.—Lady Mary Currie, Miss Willmott, and Chancellor.  
 Orange.—Gorgeous, Countess of Powis, and Meteor.  
 Crimson.—King Edward VII., Salopian, and Mars.  
 Cerise.—Coccinea.  
 Lavender.—Lady Grizel Hamilton, Countess of Radnor, and Lady Nina Balfour.  
 Blue (Dark).—Navy Blue, Captain of the Blues, and Duke of Sutherland.  
 Blue (Light).—Emily Eckford and Countess Cadogan.  
 Violet.—Duke of Westminster and Duke of Clarence.  
 Mauve.—Mrs. Walter Wright, Dorothy Tennant, and Admiration.  
 Marone.—Othello, Black Knight, and Stanley.  
 Magenta.—George Gordon, Lord Kenyon, and Calypso.

II.—BICOLORS.

Rose and White.—Triumph, Royal Rose, and Little Dorrit.  
 Pink and Buff.—Agnes Johnson, Venus, and Countess of Lathom.  
 Scarlet and Pink.—Prince Edward of York.  
 Rose and Buff.—Jeannie Gordon.

III.—FLAKES (WHITE GROUND).

Red.—America and Aurora.  
 Blue.—Princess of Wales and Senator.

IV.—FANCIES.

Duchess of Westminster.

V.—PICOTÉE.

Maid of Honour, Golden Gate, and Lottie Eckford.

RIVIERA NOTES.

MENTION has been made of the Strawberry Grape, I see. Only to-day have we eaten, with regret, the last bunches of this high-flavoured Grape, which we think so delicious. Whether it is so desirable when grown in a vinery is a question of individual taste, for it could not be a profitable fruit under glass, as its growth is so strong and the crop of fruit always rather small, both in berry and bunch, when the immense spread of foliage and growth is considered. The flavour varies according to the amount of sun it receives. The very highest flavoured examples remind one strongly of Black Currants and Raspberries mixed—not the least like an ordinary Grape. Sometimes a few berries do remind one a little of a sun-baked Strawberry; but the Raspberry-Black-Currant flavour is the prevailing "tone" to use, a mixed metaphor.

Buddleia ASIATICA, it seems, is coming to the front again. Under many synonyms it has been grown for long years on this coast; indeed, I first inhaled its delicious odour when driving "Vetturino" on this coast near the Osteria del Matto, made famous by Ruffini in his "Doctor Antonio," and it is amusing to think it should have been considered a new plant by anybody that is cognisant of gardening and gardens on this coast. I have never seen it injured by the hardest frosts here, so it must be pretty hardy, and should thrive on a south wall, where Solanum jasminoides flourishes. Buddleia asiatica, Chimonanthus fragrans, and Lonicera fragrantissima are a trio of sweet-scented winter-blooming shrubs no garden lover should be without.

PRIMULA MEGASEFOLIA is a charming little thing like a miniature Polyanthus, rose-lilac and golden-eyed, on slender stems, and if any hybrid can be obtained between it and obconica, or some Polyanthus of its own colouring, a more vigorous and useful garden plant may be obtained. There is a charm about it that is entirely lacking in P. obconica, which, never-

theless, is welcome here for covering the ground in shade under shrubs and trees; but in sun or any exposure it loses its colour and looks shabby.

PRIMULA KEWENSIS is now in bloom, and is a stronger grower than its parent, *P. floribunda*; but I think the finest forms of *P. verticillata* are superior to it, as the stems are sturdier and the shade of yellow preferable to that in *P. kewensis*, which, however, flowers earlier.

TACSONIA MILITARIS produces a few magnificent blooms throughout the winter months, but its growth is so straggling, and the flowers so few, it is not to be compared to the old and excellent *Tacsonia* I grew, which also the other day figured as a new climber, much to the surprise of those who recognised in the plate a familiar friend.

HELIOTROPE TIXIER PERE.—

While the typical Peruvian Heliotrope is the most free and persistent bloomer here throughout the winter to be seen in every fairly sheltered garden, the deeper lilac and purple forms have generally proved much more tender, so that they look unhappy, yellow, and pinched by any cold rains and winds. Up to the advent of this variety President Garfield was the best purple-flowered Heliotrope for winter flowering, but even that was apt to look chilled and ill at ease; so Tixier père, which is a fine flower, rich in colour, and bold in individual pip, is a most welcome addition, as it seems quite as free and hardy as the type. It should be useful for summer bedding in England, where the dark Heliotropes are not always happy in cold and wet seasons north of the Trent. This variety is as fragrant as the type, which is also an advantage not shared by many of the deeper coloured forms.

LINUM TRIGYNUM is most excellent in combination with, or contrast to, the blue forms of the Chinese Primula; both prefer the shade, and their colours are far fresher when so grown than plants in the open. It must generally be grown too warm in English houses, as it is in perfection when the shade (day and night temperature) averages 48° to 50°, and no red spider or thrip touches it when grown out of doors.

LINUM TETRAGYNUM is much dwarfer and less free in every way; but it flowers after *L. trigynum*, and its pale corollas are pretty if not so abundant. In consequence it is rarely grown out here, as *L. trigynum* will always take care of itself, and "come up smiling" when flowering time has arrived, even after severe summer drought. This season has suited

PHLOX DRUMMONDI particularly well, or else the strain is better than usual, for I never saw it to such advantage in the month of January. As an edging to a good-sized bed of Tree Carnations it is specially attractive, for the tones of its flowers harmonise admirably with the mixed strains of Carnations grown for winter bedding. The combination, perhaps, might also look well in English gardens where Carnations are used in bedding. I see it is announced that a big show of Tree or winter Carnations is to be held at Cannes from March 3 to March 7. It is to be hoped that

the newly-raised French perpetual flowering Malmaisons may be shown there.

EDWARD H. WOODALL.

TREES AND SHRUBS.

THE SUGAR MAPLE.

THIS is a sadly neglected tree. Although introduced from North America so long ago as 1735, it is but rarely seen in this country. The illustration of a tree growing on the bank of the lake at Pencarrow gives a good idea of its appearance

leaf colouring which we associate with that season. But at Pencarrow our Sugar Maple never fails to furnish us with a wealth of glorious colour, the effect of which, when reflected by the still waters of the lake on whose margin the tree stands, is indescribable. The Sugar or Rock Maple (*Acer saccharinum*) forms extensive forests in Canada. Formerly the tapping of these trees in spring was quite an important undertaking. The juice so obtained, when boiled, deposits a dark-coloured crystalline mass—Maple sugar. Although considered to be quite equal to cane sugar, it but rarely found its way into commerce. The grain of the wood, which varies considerably in appearance, furnishes the "blister" and "bird's-eye" Maple valued for inlaying.

A. C. BARTLETT.

OLEARIA RAMULOSA.

THIS is an interesting Australian shrub which is well worth growing for the greenhouse in winter, for it is light and graceful, is easily grown, and flowers freely. Although by no means new, it is rarely seen in cultivation, Australian plants generally being neglected in most gardens. In the temperate house at Kew one or two good plants of it may now be seen in flower. These were raised from seed received from the Sydney Botanic Garden in 1901. In general appearance it differs considerably from the better-known species of *Olearia*. The main branches are made up of numerous twiggy side branches, clothed with tiny leaves barely an eighth of an inch long, green on the upper surface, and covered on the under side with a white felt. The flower-heads are white and star-shaped, and are borne from the axils of the leaves on the upper portion of last summer's wood, the upper half of a branch forming one large inflorescence. Individually the flower-heads are small, being barely a quarter of an inch across. Their lack of size is, however, made up for by their profusion. A cool greenhouse is all that is necessary for the cultivation of this plant, and during the greater part of the year a cold frame will suffice.

W. D.

ILEX CRENATA.

A NOTABLE feature of this pretty little Japanese Holly, figured in THE GARDEN, page 413 of the last volume, is the readiness with which it can be raised from cuttings, for Hollies are, as a rule, very difficult of increase in this way. If the half-ripened shoots are taken during the latter part of the summer, inserted in pots of sandy soil, and placed in a frame kept close and shaded from the sun, they will in many cases root before winter; at all events, they will be fit to pot off in the spring. Apart from the variegated-leaved variety there is one known as major or Fortunei, in which the leaves are larger and rounder and the plant itself rather more vigorous than the type. Professor Sargent, in his "Forest Flora of Japan," gives some interesting particulars concerning this Holly, as follow: "Ilex crenata is the most widely distributed and the most common of the Japanese Hollies with persistent leaves. This plant is abundant in Hokkaido, on the foothills of Mount Hakkoda, and on the sandy barrens near Gifu, on the Tokaido, and I encountered it in nearly every part of the empire which I visited. It is usually a low, much-branched, rigid shrub, 3 feet or 4 feet high, but in cultivation it not infrequently rises to

THE SUGAR MAPLE (ACER SACCHARINUM) BY THE LAKE AT PENCARROW, CORNWALL.

when developed. This tree was planted a year or so prior to 1850, and is now just 40 feet high, and the stem at 3 feet from the ground measures 3 feet 4 inches in girth. The photograph was taken last April when the tree was in flower. At this period it is very attractive; each shoot produces a short-stemmed, drooping corymb of flowers, which are of a delicate pea green colour. On a warm sunny day, or when a cut branch is placed in a warm room, the flowers emit a pleasing fragrance.

But, beautiful as the Sugar Maple is when in flower, it is still more beautiful in the autumn. During the past autumn one heard frequent lamentations concerning the lack of

the height of 20 feet, and, assuming the habit of a tree, is not unlike the Box in general appearance. The leaves, which are light green and very lustrous, vary considerably in size and shape, although they are rarely more than an inch long, and are usually ovate-acute, with slightly crenate, toothed margins. The black fruit is produced in great profusion, and adds materially to the beauty of the plant. This is the most popular of all the Hollies with the Japanese, and a plant usually cut into a fantastic shape is found in nearly every garden. *Ilex crenata* and several of its varieties with variegated foliage were introduced into western gardens many years ago, and are occasionally cultivated, although the value of this plant as an under shrub appears to be hardly known or appreciated outside of Japan."

H. P.

## A JOURNEY TO UGANDA.

THE now completed railway from the shores of the Indian Ocean to those of Lake Victoria Nyanza enables one to see a good deal and get a good general idea of the East African Protectorate. Leaving Mombasa by it one travels through long stretches of Coconut plantations thickly studded with picturesque native huts. Succeeding on this comes a fairly interesting country of a hilly character, so much so that the track winds and turns on itself frequently. One enters next on a hot, bad smelling, uninteresting stretch of country, which one is glad to leave and come to the class of scenery that seems common at about 3,000 feet altitude in East Central Africa. This is a region of thin, clean forest, of wide grassy expanses, and of conical hills often clothed with bush. Then comes another rise in altitude and we are on those vast, almost level, almost treeless, plains so characteristic of this region of East Africa. Over immense distances the only vegetation practically is grass, rarely more than 2 feet high and often quite short.

But one is apt to forget those grassy seas in the astonishment aroused by their inhabitants. These are members of the gazelle family, and zebra, in extraordinary numbers. And they are not all away in the distance, for thousands graze comparatively close to the track. A charming buck (Thomson's gazelle), smaller than a fallow deer, goes in large herds. The quaint, long-faced hartebeest, with its rich yellow-brown coat, is in lesser numbers but always

picturesquely grouped. There are rietbuck and buck of various other sorts, but they do not occupy the picture as effectively as the sturdy, healthy mobs of zebra; while the many stately, long-necked ostriches are a prominent feature. Probably here we have the last stronghold of that unique, sub-tropical African fauna which the white man, in occupying the country in days gone by, has ruthlessly destroyed. Probably also there is no country now so fully stocked with game, and it is almost worth the journey to observe these interesting animals on their own ground.

On the outskirts of the plains another sight, as wonderful as the vast game lands, is impressed on one's memory. I mean the view, looking south, of

### THE FAMOUS KILIMANJARO MOUNTAINS.

Seen just after dawn across the plains, out of which the stately range appears to rise, nothing can be more impressive. The great peaks (nearly 20,000 feet high) covered perpetually with snow are coloured the most beautiful tints—generally rose or rose-pink—by the rising sun. The enormous upsweep of slope seems then so clearly lighted that one imagines details of rock and chasm to be discernible. As if by magic, strata of cloud form on the sides and as mysteriously disappear. Indeed, while gazing, the whole range may appear to vanish into cloudland, for, with a due sense of its majestic grandeur, Kilimanjaro does not always expose to the common gaze the whole of its vast proportions. In this region of the great plains there are three charming lakes—Elementeita, Naivasha, and Nakuro. Nakuro is almost surrounded by well-timbered hills of varied and pleasing outline, and here again begins the rise to those delightful higher plateaux which extend over a large area. These plateaux, and the plains they rise in, are admirably adapted for white colonists. The land is fertile and well watered, timber is plentiful, and the climate is almost perfect. We find here a *Podocarpus* and a couple of species of *Juiper*—the latter forming almost pure forest at times; but both are more frequently seen mixed with other *Dicotyledonous* trees. The scenery in these highlands is of great variety and exercises a powerful fascination on the visitor. Many parts are exquisite, such, indeed, as we ascribe to fairyland. They are bits of Nature's own gardening. It follows that these spots are of special interest to the plant-lover. There linger in one's memory beautiful effects of trees and shrubs, low-growing flowering

plants and Ferns noticed *en route*. The vegetation is rich in types, and no doubt many first-rate garden plants will be forthcoming from these plateaux.

The railway track descends from its highest point (over 8,000 feet) on the Mau escarpment to the shores of Lake Victoria. Oddly enough, when nearing the Lake an unpleasant bit of country, suggestive of that near the sea-coast, is traversed. The dominating vegetation here is a species of *Acacia*, with pale green stems and very scanty foliage, which is common in parts of Central Africa and known as "Fever Tree"—the country it inhabits suggests fever and kindred evils. On making the acquaintance of the Lake at close quarters a feeling of disappointment is experienced, for you are landed at the head of Kavirondo Bay, and it is not by any means the prettiest margin of the "Great Water." Taking the steamer here and gaining the Lake proper you quickly perceive how grand an expanse of water it is. A spacking breeze frequently blows in the forenoon and the water can be as blue as the Mediterranean. When it is lashed into fury by storm it is easy to imagine oneself on the ocean. As the route across to Uganda lies, one is rarely out of sight of land, so numerous are the islands, which are frequently picturesque and interesting. On an average fair evening the

### LAKE SCENERY

is peculiarly fascinating. One is apt to forget he is almost in the heart of Africa, for there is a strange sense of familiarity in the surroundings. The Lake shores of Uganda proper, whether viewed from the water or from the land, are picturesque in the extreme. There is frequently a striking belt of tropical forest, with magnificent stretches of *Raphia monbuttorum* on the water side; and there is often to be found, leading up to this, a beach of delightful sandy gravel of a white colour. The coast-line is indented by beautiful bays, and sometimes the shore-line is a series of low, irregular cliffs of a brown volcanic conglomerate, clothed with a short wiry grass, very pleasant to walk on; indeed, there are often wide expanses of land on the shores covered by this grass. It is also to be remarked that most unpleasant swamps composed of towering *Papyrus*, *Arundo*, and a tall, common-looking *Ruscus* are to be found—haunts of many waterfowl.

The very interesting "Ambatch" tree (*Hermiera elaphroxylon*) bears the same relation to places on the Lake shore that mangroves do to estuaries on the sea-coast. It forms a dense jungle just inside the water-line, and follows that position persistently. I have no doubt it serves the purpose of aiding the land in encroaching on the Lake, for all sorts of *debris* accumulate amongst the serried trunks. But it is interesting to observe that the tree thrives best where its trunk is immersed 3 feet or 4 feet in water; its exceedingly light, cork-like wood appears to have little or no use in native economy. The Basoga used it formerly to make their peculiar war-shields, and some considerable trade is done now in making more or less correct copies of these and selling them at a big profit to the newly arrived white man, who, to the joy of the native, is an assiduous collector of "curios"—often at fancy prices. An isolated tree, or small group, of the "Ambatch" forms a favourite site in which colonies of black and yellow weaver-birds build their interesting nests. The place is literally alive with these garrulous but industrious birds when building operations take place.

### THE LAKE SHORE FOREST,

although at nearly 4,000 feet altitude, contains vegetation of the most tropical lowland types. The common *Raphia* attains very fine proportions, and clumps of a *Phoenix* tower aloft gracefully. There are many striking species of *Ficus*, and at least one fine foliaged *Macaranga*. The wild Nutmeg (*Pycnanthus*) is ever present, topping most of the forest trees, except the noble *Piptadenia*, which frequently forms at its base remarkable buttresses. The Incense tree (*Canarium*), with its great bole and widespreading limbs, suggests a fine Oak. A striking white-flowered tree is the beautiful *Baikaa insignis*, which makes a fine show in its flowering periods.

SNOWDROPS BY STREAMSIDE AT DUNROBIN, A RESIDENCE OF THE DUKE AND DUCHESS OF SUTHERLAND.

SIR H. JOHNSTON'S FAVOURITE TREE, the blazing Erythrina, is often a dazzling splash of colour on the skirts of the forest. Landolphins scent the air and litter the ground with their beautiful flowers; their fruits—in shape and colour like Oranges—are loved by the ubiquitous monkeys. A large percentage of the older trees have their trunks wreathed with an Aroid (Culcasia), and a graceful Piper with clusters of yellowish red fruits is also a common climber. But one tires of the ever-present, overwhelming Lianas, their tough, sinuous stems seem to compose the forest in some cases. The Ginger family furnishes plenty of growth for the forest floor. A beautiful Thalia with large, baccate, bright red fruits is very effective. There are several species of Amomum, and a Hæmanthus occurs in large patches where the shade is not too dense; in flower it makes a charming picture. Ferns of a few acaulescent genera are plentiful in places, but not always common. One recalls charming pictures made by masses of Ferns in Raphia groves on the Lake shore where the shade is pleasant and the soil moist and peat-like. Not only is the ground covered with Ferns, but the Palm trunks are gracefully wreathed with

LYGODIUM SCANDENS,

while the persistent bases of the leaf-stalks furnish "pockets" wherein Ferns, Ficus seedlings, &c., find a suitable home.

Proceeding inland, one leaves this forest and encounters a country remarkable for its bumpy character. There are many little hills dotted about, and the valleys between are frequently swampy. This mostly obtains in Southern Uganda; and it is to be remembered that there are always Bananas—the country-side is often covered with plantations of them—Bananas without end. It is an ideally lazy existence—that of a Baganda. You plant up your Bananas and sit in the shade for the remainder of your days, while your wives do the little cultivation needful. Uganda generally is a

MOST PICTURESQUE

and interesting country. Already a considerable literature has grown up about it. I believe it has a promising commercial future, and it ought to go ahead if the health of the white men engaged in the task of whipping it into shape can be assured. Unfortunately for them and for it a great many breakdowns occur. It is hard to convince even those who know it that such a charming country can have so much disease lurking about.—J. MAHON, in *Kew Guild Journal*.

NOTES ON HARDY PLANTS

SNOWDROPS IN DUNROBIN CASTLE GARDENS.

WHERE these bulbs are naturalised in large numbers throughout the wilder portion of the garden and in the woodland, no flower of early spring can produce such a charming effect as the white carpet of Snowdrops, excellent examples of which are shown in the accompanying illustrations, from photographs taken in the gardens at Dunrobin Castle, a residence of the Duke and Duchess of Sutherland.

Mr. David Melville, the head gardener there, wrote an excellent article on the Snowdrops at Dunrobin in THE GARDEN of

WHITENED WITH SNOWDROPS: A WINTER PICTURE AT DUNROBIN.

September 26, 1903, and for fuller information concerning them reference should be made to the notes there published.

GALANTHUS CILICICUS.

I RECEIVED a few bulbs of this Snowdrop from a firm of seedsmen late in October, 1902. Some I planted at once in a pot in a cold frame, and some in a clump in a sheltered spot outside. Those in the pot threw up leaves, but none of them flowered.

Of those planted in the open several flowered at the end of November of the same year. This season they are only now (the 9th inst.) opening their blooms, but the latter are more numerous and the plants look stronger and more healthy than they did last year. From this behaviour one is tempted to think that they are gradually reverting to what seems to be the natural flowering season of the Snowdrop in this climate, viz., early spring. I should very much like to hear the opinion and the experiences of any of your other correspondents who have grown this Galanthus. Is it the same as Galanthus octobrensis?

Rye.

F. H. C.

[Galanthus cilicicus is a species from Cilicia, and octobrensis a variety of the common Snowdrop.—Ed.]

SEDUM PULCHELLUM IN MIDLOTHIAN.

THE true Sedum pulchellum is a comparatively scarce plant, but I saw a good specimen of it lately in the garden of Mr. Robert Lindsay of Kaimes Lodge, Midlothian. It is one of the United States species, and, unfortunately, rather tender—a fact which probably accounts for the rarity of its appearance in gardens. It is of evergreen habit, varying a little in character, some plants being trailing and others more erect. The branches are rather slender, while the rosy purple flowers are on a branching cyme, and are about half an inch in diameter. The leaves are thickish and rather pointed in form. It would appear to require a

sheltered position, and it is desirable to protect it from excessive rainfall in winter by a sheet of glass placed overhead.

S. ARNOTT.

NEW BEGONIAS AND THE WEATHER.

THE past summer has been truly disastrous for the general run of outdoor flowers. The Begonia alone has been but little affected by the rain and cold, and never yet has its superiority over all other flowers, from the point of view of resistance to the too frequent intemperate summer weather of the north of France, been more conclusively proved. Neither hail nor rain has been able to spoil it, or, at most, but temporarily. After the heaviest rains but very few flowers were destroyed, and, others immediately opening, the vacant spaces were at once filled. At the time of writing (the end of September) beds of Begonia semperflorens (Triomphe du Belvédère, elegans, and Triomphe de Boulogne) are in splendid condition, and have been so all the summer; not a plant is spoiled. A stand carrying 250 varieties of double Begonias is still very beautiful. It should be noted that all these Begonias flower continuously from the beginning of June. Now what, on the contrary, can be said for their neighbours the Pelargoniums, Cannas, &c., if not that they present a truly pitiable aspect, and in order to recall their few days of beauty the memory must be carried back to the early summer, before the middle of July.

The experience of the last two years abundantly proves the superiority of the Begonia. In the north of France Begonia semperflorens is decidedly without a rival for garden decoration. Those who complain that its colouring is too dull certainly do not know the varieties which I have mentioned above. It is impossible to find a fresher and prettier pink than that of Begonia elegans. Triomphe du Belvédère is of dwarf habit, with red flowers and bronze foliage; Triomphe de Boulogne of medium height, with deep pink flowers and foliage of a brilliant purplish red; the effect being most harmonious. Although I have tried nearly all the varieties I have not yet found any

better than these three. Mention must, however, be made of a recent plant, *B. Lubeca*, which very much resembles *B. elegans*, but which is semi-dwarf, and throws out many suckers from the root, a valuable quality in plants used for massing. For these reasons I think it will be interesting to follow up this novelty.

During the past two or three years we have welcomed the appearance of a large number of double *Begonias*, both in France and abroad. Up to the present, England alone has been able to rival our producers, one of the best of whom, M. Crousse, of Nancy, is retiring from business. It is to be hoped that his successor will continue his work with the same success in his nursery at Vésinet.

On the occasion of our horticultural exhibition I had the pleasure of meeting the Rev. Edwin Lascelles, one of the most celebrated English producers of *Begonias*. He greatly admired our double *Begonias*, taking exception, however, in a general way to the want of vigour and poor habit of our plants produced from seed. As this is exactly the fault I have to find with the English novelties, I think the cause will be found in the difficulty of acclimatising the plants, for, in my own case, cuttings of a large number of English varieties furnish vigorous specimens, while others, it is true, remain very delicate.

Complaint is also made that the flower-stalks of our French novelties are too long and consequently too flexible. This is a real fault, but very few large-flowered double *Begonias* escape it, and I must confess that, in my opinion, neither race possesses any advantage over the other.

The English novelties, as I stated in a former article, showed a marked superiority in the deeper coloured varieties. This year, however, our producers register a success in this direction with, amongst others, Jarry Desloges, of which the velvety appearance and brilliance equal, if they do not excel, those of *Nero*, *Lord Llangattock*, &c. On the other hand, we have not yet plants equal to *Picotee* and *Samuel Pope*, but it must be said of our neighbours that they have obtained nothing better than these two old *Begonias*. *Mistress James*, *Partbury-Marabella*, &c., can be considered, without doubt, as interesting gains, but they are not so good as their parents.

But what a number of beautiful double *Begonias* have been raised in France during the past few years. Among the best are *Mme. Emile Nicolas*, whose deep rose-carmine flowers have an enormous white centre; *Nouveau Jeu*, one of the most beautiful *Begonias* known, free-flowering and vigorous; *Univerael*, a fine large-flowered plant; *Merveille*, *Mme. Charles Lepidi*, *Gabrielle Pierrette*, a splendid plant with large white flowers; *Hélène*, *Thérèse Benoit*, *Mme. Léon Gosgean*, *M. Tranchant*, *Mousseline Explosion*, *Princesse Tatiana*, *Avenir Apollon*, *Mme. A. Tarbary*, *Général Annenkof*, *M. Luby*, *Carolus Duran*, *Roi de Siam*, *Welleda Unique*, *Avant Garde*, *le Klondyke*, &c.

R. JARRY-DESLOGES, in *Le Jardin*.

## A YEW PERGOLA AT MONTACUTE.

THE illustration depicts a pergola such as is seldom seen in gardens; it is a natural arching of Yew, and is a quaint picture in beautiful Montacute, the residence of Mr. W. R. Phelps. At Montacute walled courts or terraces com-

mand extensive views of the surrounding country. Clipped Yews are one of the chief features of the place, and add much to its interest.

## THE ROSE GARDEN.

### JOTTINGS ABOUT ROSES.

IN gardens where large numbers of beds are devoted to the costly systems of sub-tropical gardening and the use of tender plants generally, one not infrequently hears complaints from gardeners of being short-handed, and, in consequence, overworked. Indeed, shortness of labour seems a general complaint in the majority of gardens, and it is there-

A YEW PERGOLA AT MONTACUTE, SOMERSETSHIRE.

fore surprising to find how unwilling their owners often are to give up the use of tender things, which are always troublesome and expensive to maintain and keep through the winter, in favour of the many noble hardy plants, in every way more fitted to stand our changeable climate.

The question of planting large permanent beds with hardy flowers is of more than passing interest, and, as I hold that we cannot accomplish this successfully if we overlook the claims of the vigorous semi-climbing and shrub-like *Rosea*, I shall not be out of place if I deal with the subject here.

Looking back during the last decade, it is astonishing to find what a number of grand *Rosea* of hardy and luxuriant growth have been raised, and there is no need—provided we use these rightly—for our flower-beds to be flat and unimpressive.

First of all, however, we must break away from all ideas of compactness and formal rows and use these free-growing *Roses* in conjunction with the nobler hardy flowers, especially those which are fine and enduring in leaf and will thus have a good effect during winter. Bearing in mind that the beds will probably stand undisturbed for some years, their preparation must be thoroughly done. The minimum depth of good soil should be 3 feet, and on cold, wet soils it will be necessary to ensure that the beds are well drained.

One of the best and most striking examples of a large permanent bed that I have seen as yet was formed by grouping a few plants of that magnificent hybrid *rugosa*.

CONRAD FERDINAND MEYER,

raised by one of the most skilful rosarians on the Continent, Dr. Muller, and distributed by Herr

Otto Froebel of Zurich in 1899. One of the earliest to flower, each plant forming a bold and vigorous shrub or small tree, this variety is very suitable for grouping in the most exposed positions, and will relieve any lawn of flatness. With its splendid La France-like flowers and its ample foliage, it is worthy of a prominent position in any garden, whilst it is, moreover, perfectly hardy, and requires no protection whatever. Somehow or other this *Rose* has become known in nurseries under the erroneous name of *Consul F. Meyer*. In the current volume of the *Journal of the Royal Horticultural Society* there is, amongst those invaluable "Notes and Abstracts" (page 290), an interesting note about this *Rose*, taken from the well-known German gardening paper *Die Gartenwelt*, which shows how much it is appreciated in Germany.

As I have already pointed out, the use of such a strong-growing *Rose* as this affords an opportunity of planting with it some of those bold perennial plants which are good in effect all the year through, and this was done in the case of the bed referred to above, which had a broad fringe of one or other of the hardy *Megaseas* (*Saxifraga*) around it. This is only a typical example of how easy it is to form permanent beds of grand effect, which will give an added charm to many a large garden where nothing but prim and stiff beds were previously to be found. A walk through any of our best *Rose* nurseries will soon make apparent to anyone how very valuable are many of these

### SHRUB-LIKE ROSES

for this particular purpose, especially those which have the great advantage of being perpetual and hardy. The *rugosa* tribe are particularly valuable either when treated as shrubs or grown as large standards. Those which I can recommend with confidence are *Blanche Double de Coubert*, *Mrs. Anthony Waterer*, *Mercedès*, and *Thusnelda*, the last two varieties not being very well known as yet. I have seen some handsome beds made by using these *rugosa* *Roses* in standard form. One bed was composed of half a dozen fine standards of the exquisite free-flowering *Blanche Double de Coubert*, the ground beneath being hidden with the rich-toned leafage of *Heuchera glabra*. It requires but little thought to call to mind many fine-leaved hardy plants which associate well with these splendid vigorous *Roses*. The hardy forms of the

### MEGASEAS (SAXIFRAGES)

are always good in effect, and give bright colour after the first frosts of autumn and winter. Their

great merits are often forgotten, and one but rarely sees them employed to the best advantage. In "Wood and Garden" Miss Jekyll gives us proof of their great usefulness, and points out the enduring beauty of their foliage. No plants are better fitted for the purpose of edging bold groups of Roses than some of the hybrid forms raised by Mr. T. Smith in his far-famed Irish nursery. To mention a few of the sorts: Sturdy, Progress, Campana, Distinction, and hybrida splendens are all excellent, not too strong in growth, and therefore more suited to this treatment. Croesus, the smallest of all, has very lovely foliage, and is such a miniature that it could well be used as a ground-work to the dwarfier Tea Roses. In addition to the bold-leaved Rockfolies just named, there are many other suitable plants whose beauty of form is better displayed when they are grouped either in picturesque masses amongst the Roses or placed as a bold edging. Such are the Heucheras—glabra, Richardsoni, micrantha, zabeliana, and others—with their massive deep-tinted foliage constant through all seasons. Flag Irises, too, are always good when thus treated, and, as may be seen in the Bath Botanic Garden, form a good contrast to the Roses, and do not appear to impoverish them. Tellima grandiflora purpurea is striking when thus used, and only surpassed by a new form which I recently received from Messrs. Lemoine under the name of Tiarella (Tellima) purpurea major marmorata, whose foliage is resplendent with silver and purple marbling. Then there is a host of Ivies, and if we are careful only to choose kinds of cheerful colouring and grow them upon their own roots, the effect will be good in any position.

Above all, when forming the beds, we must not omit the many beautiful flowering bulbs which will give colour in spring. It is almost unnecessary to give a list of the Roses suitable for this planting. The rugosa varieties, as I have stated, are invaluable, because the majority of them are continuous blooming and very hardy, so also are Dawn, Mme. A. Carrière, Reine Olga de Wurtemberg, Aimée Vibert, Purple East, and the hardiest of the race of Dijon Teas, amongst which I might mention Bouquet d'Or as an excellent example. All these are perpetual, and will make grand shrubs if not allowed to suffer too much from the pruning-knife. We want still more of these shrub-like Roses with a perpetual habit, as though such exquisite kinds like Una, macrantha, Andersonii, and the now numerous ramblers form splendid bushes, their beauty is so soon over that they are really more suited for the less formal parts of the garden. People in this country have grown so accustomed to the use of trim and symmetrical beds within sight of the windows of their houses that one seldom sees anything but this common place way adopted. I have attempted in these notes to show how those who have sufficient space at their command can break away from the old ways of planting such beds and get good effects, as well as real beauty by using the splendid shrub-like Roses which hybridists have bestowed upon us, with inexpensive hardy flowers.

Worcestershire.

ARTHUR R. GOODWIN.

USES OF BRITISH PLANTS.

CUPULIFERÆ.

OAK (Quercus Robur).—The two varieties (Q. R. pedunculata and Q. R. sessiliflora) are too well known to need description. The wood for timber and the bark for tanning, as well as the acorns for pigs, have been used for ages. The fine avenues of Oaks in and near Cape Town were first planted by the Dutch for the sake of the acorns. In "Domesday Book" the ancient Oak forests were described as being of so many "hogs," i.e., capable of supplying acorns. The soft "Oak apples," as well as the hard galls, appear to have been used in the Middle Ages for making ink. Ink with wine was an antidote for an adder's poison. Also, ink, honey, and the white of an egg was used for sore eyes. The "bog Oak" of Ireland is stained black with tannate of iron, the same thing as ink.

Beech (Fagus sylvatica).—This familiar tree has a close-grained wood, but is not much used as timber, because changes from drought to moisture tend to its decay rather rapidly; but for furniture, screws, &c., and other work of coopers and turners, much use is made of it. It is remarkable for its great durability under water, hence its applicability for piles. In France sabots are made of it. After being soaked in water and then subjected to smoke it has proved durable as planks. On the Continent charcoal is made from

Hornbeam (Carpinus Betulus).—This tree, especially abundant in Hertfordshire, has a wood suitable for agricultural implements, mill work, &c. It used to be employed for the "beams" or yokes placed under the horns of cattle, hence its name. The bark yields a yellow dye, which is used in Sweden.

SALICACEÆ.

Willow, Osier (Salix viminalis and sp.).—Sever: 1 species, varieties

or hybrids, for many of the last are wild, are grown for the long annual shoots. The different degrees of slenderness or otherwise renders them useful for various kinds of basket work, hampers, &c. In some, as Rose Willow (S. Helix), there is a considerable amount of the substance salicin, which is used medicinally, having analogous properties to those of Cinchona Bark for fevers. The Willows grown for their branches are S. alba, S. cinerea, and S. fragilis. These are converted into "pollards," the shoots being cut every five or six years, when they are sufficiently large for fences, casks, poles, &c. The bark of Willows contains a considerable amount of tannin, and is useful for making leather.

BETULACEÆ.

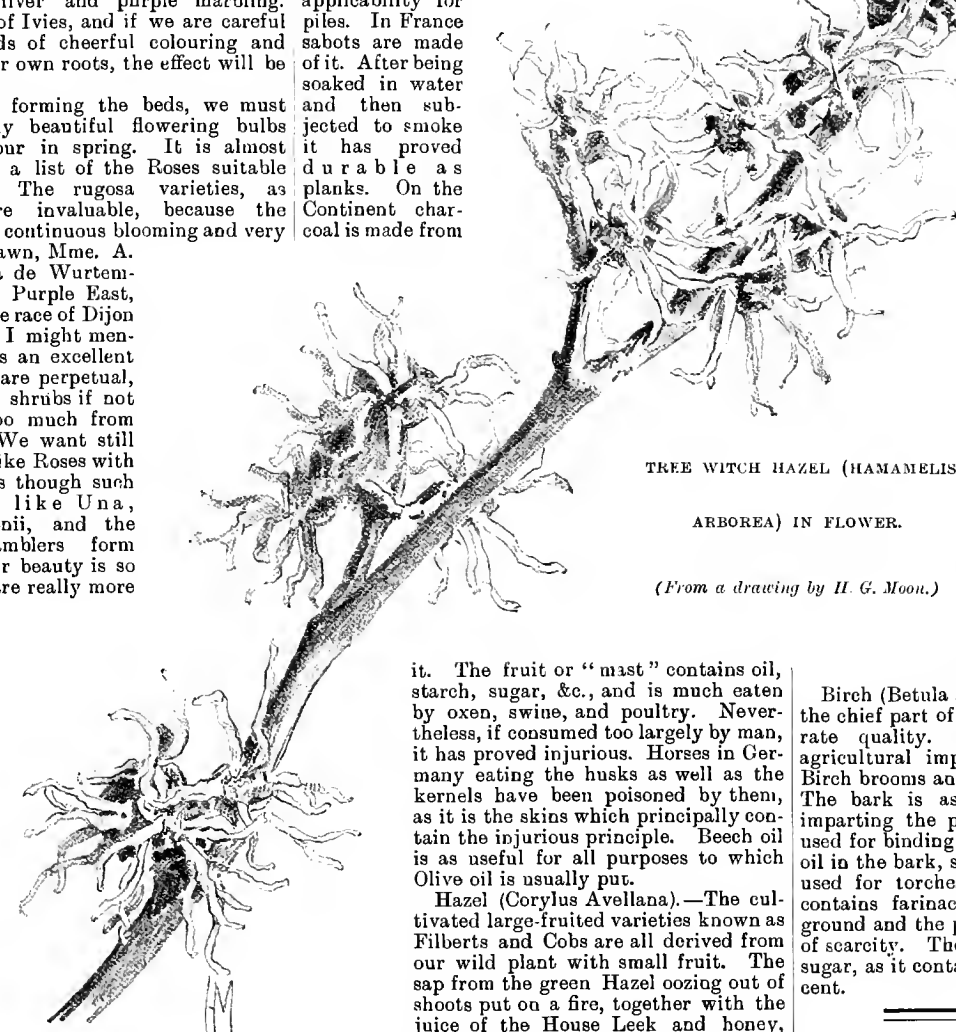

Birch (Betula alba).—The timber of this tree is the chief part of any service, but it is not of first-rate quality. Wheelwrights and makers of agricultural implements employ it. Of course, Birch brooms and school birches are well known. The bark is astringent and used for tanning, imparting the peculiar odour to Russian leather used for binding books. There is a great deal of oil in the bark, so much so that it has often been used for torches in high latitudes, and, as it contains farinaceous matter, the bark has been ground and the powder mixed with flour in times of scarcity. The sap is sometimes tapped for its sugar, as it contains a small quantity, about 2 per cent.

G. HENSLOW.

THE WITCH HAZELS.

(HAMAMELIS.)

AMONGST an array of winter-flowering shrubs, such as the Winter Sweet (Chimonanthus), golden winter Jasmine, Cydonia japonica, Cornus Mas, Nuttallia cerasiformis, Clematis cirrhosa and Laurustinus in variety, there are none that take

TREE WITCH HAZEL (HAMAMELIS ARBOREA) IN FLOWER.

(From a drawing by H. G. Moon.)

it. The fruit or "mast" contains oil, starch, sugar, &c., and is much eaten by oxen, swine, and poultry. Nevertheless, if consumed too largely by man, it has proved injurious. Horses in Germany eating the husks as well as the kernels have been poisoned by them, as it is the skins which principally contain the injurious principle. Beech oil is as useful for all purposes to which Olive oil is usually put.

Hazel (Corylus Avellana).—The cultivated large-fruited varieties known as Filberts and Cobs are all derived from our wild plant with small fruit. The sap from the green Hazel oozing out of shoots put on a fire, together with the juice of the House Leek and honey, was put into the ear to cure deafness, while the burnt bark powdered was blown into the nostrils to stop them bleeding in the Middle Ages. The straight shoots of the underwood are useful for walking sticks, crates, hurdles, and cask hoops. Burnt they supply artists' charcoal, while knotted roots are used for veneering.

the eye and interest visitors so much as the different kinds of Witch Hazels. Of course, the untimely flowering of the Glastonbury Thorn is always of interest, but even that is a Hawthorn after all, the point being its blossoming at the birthday of the year, or even earlier. The different species of Hamamelis are natives of North America, North China, and Japan, and, with their less well-known relatives *Bucklandia*, *Corylopsis*, and the *Liquidambar*, are found in our gardens to-day. The popular name of Witch or Wych Hazels seems to have become attached to them from some old superstition that they afforded the twigs used in the ritual of divination. Be this as it may, the plants themselves have no botanical affinity with true Hazels (*Corylus*), but with the three other genera above named they enjoy a small natural order (*Hamamelidae*) to themselves. It is, however, as ornamental garden shrubs that they best deserve notice, two species being very beautiful in winter. These are *H. arborea* and *H. japonica zuccariniana*.

*H. ARBOREA*, in its native habitats in Japan, grows 15 feet to 20 feet in height, and has purple-red flowers (calyces) with crimped or crumpled petals, like little bits of gold wire. The branches are olive or greyish brown, and the buds are of a rich fox colour. Even quite small plants are thickly set with their quaint flowers, and look very pretty on the grass with a background of sombre shrubs. A little branchlet or two in an old bronze bowl on the breakfast table is a surprise to most people fond of flowers. The other species,

*H. JAPONICA*, has a more lax habit and pale lemon-yellow petals, but is at the same time extremely graceful and effective. It is wild in North China and Japan. *Zuccariniana* is a variety. A third kind is the better known

*H. VIRGINIANA*, which flowers in September just as its leaves die off a mass of pale golden yellow. It is a strong grower, soon attaining a height of 10 feet or 12 feet. *H. arborea* and *H. japonica* make attractive plants for pot culture in a cold or cool house.

## GARDENING OF THE WEEK.

### FRUIT GARDEN.

#### PLANTING.

FROM various causes this work has been considerably delayed. It should now be done whenever the weather permits. In the planting of standard trees the stations should be well prepared, 3 feet in diameter and 2 feet in depth, breaking up the soil well at the bottom of the hole. In planting the trees keep the roots near the surface, mixing in amongst them some good loam and wood ashes. Do not use any manure when planting, but mulch the trees after. Stake the trees to prevent waving about, and examine the ties later when the soil has settled down. I have not seen Mr. Beckett's latest invention, which should have a great advantage over tying with twine. Standard trees should be planted about 25 feet apart, more or less, according to the variety; pyramids or bushes, 9 feet to 12 feet.

#### PRUNING.

Standard trees in orchards are often neglected, or are only thinned occasionally, and then too severely. They should be looked over annually, removing any branches that cross each other and all useless spray. Any large unfruitful branches should be removed with the pruning saw, smoothing over the surface of the cut with a pruning knife, and afterwards painted over with a mixture of clay and tar. Young standards should have any weak growths spurred back, leaving about six of the best placed to form the tree. Shorten the leaders to about one-third their length. Any newly-planted trees should not be pruned before March, and should then be carefully done.

#### PYRAMIDS AND BUSHES.

These will require little pruning if proper attention was given them during the summer.

Any young shoots overlooked should be spurred back to two or three buds, according to the variety. Any old trees that have become crowded with old spurs or branches should have a few of the worst removed annually. Gather all the prunings up and burn them, fork up the surface lightly, and give a good dressing of wood ashes. Dust the trees over with lime when damp, or syringe them with the caustic soda and potash solution so often recommended in these columns.

#### RASPBERRIES.

Where the planting of new quarters has been delayed it should now be carried out. Trench the ground, working in plenty of manure, and if the soil is heavy use plenty of old hot-bed manure and wood ashes, as the ground cannot well be too rich for these plants. Allow about 5 feet between the rows and 1½ feet between the plants, cutting them down to 6 inches in the spring when breaking into growth. The old canes which were thinned in the autumn will only require tying, leaving the canes about 6 inches apart, and topping the shoots, giving them a good mulch afterwards.

#### BUSH FRUITS.

All bush fruits should now be pruned. Thin out old Gooseberries, spurring in the side shoots to two buds. Thin those the most that are wanted for dessert. Give the trees a dusting of lime and soot, and repeat when necessary, as this helps to keep off the birds. Red and White Currants should have the side shoots spurred in to three buds, and the leading shoots cut back to 6 inches. Black Currants only need some of the old wood removed, leaving the young and vigorous shoots, as these produce the finest fruit. Give all the trees a good dressing of rotten manure, digging lightly in, taking care not to damage the roots of the Black Currants.

*Impney Gardens, Droitwich.* F. JORDAN.

## FLOWER GARDEN.

### ROCK GARDEN.

STRICT attention should be paid to cleanliness, or at this period the rock garden will present an untidy and uninteresting appearance. Any fallen leaves that have been wind-swept into the pockets should be regularly removed or they will smother weak growing plants. All weeds should be removed, and frequently stir the surface soil which has been battered down and discoloured by the persistent rains.

The valuable *Iris reticulata* and *I. stylosa* are now coming into flower in many places, and will be followed by such as *Iris histrio*, *I. caucasica*, and the sweet-scented *I. persica*. Neat supports should be given to the flower-spikes, and if the plants are exposed to rough winds it will be advisable to screen them. A few short branches of an evergreen tree placed in the soil to windward will be sufficient protection. Slugs are very destructive; many baits and methods are recommended, but it is doubtful whether anything is more efficacious than searching for them on a dry evening with a lantern, and a small vessel of lime to drop the slugs into. Moles are a great nuisance in the rockery, uprooting valuable plants. They undoubtedly devour a quantity of wireworms and earthworms, but in gardens the remedy is worse than the evil. At this time of the year they have a great liking for the rockery. Traps should be set in their main runs and at such places as where they cross under a path. A few lengths of stout Bramble or some barbed wire pushed into their runs will often drive them away. Mice will soon be at the Crocuses. When other traps fail to catch them the old-fashioned figure-four trap baited with a piece of toasted cheese is usually successful.

#### HARDY FERNS,

unless there are special reasons, such as the close proximity of the house, or there are spring-flowering bulbs planted among them, I would not recommend clearing away the dead fronds until just before new growth commences. Where spring bulbs are grown among the Ferns many of these will soon be growing apace, and a top-dressing should be applied without delay. Snowdrops are very early

this year. Last year I moved a large quantity as soon as they finished flowering, and they now promise to flower much more freely than in previous years.

#### RANUNCULUS.

Well-drained beds of rich, light soil should now be prepared for the varieties of the garden *Ranunculus* (*R. asiaticus*). Except in very warm localities it is not wise to plant the roots until towards the end of next month. A. C. BARTLETT.

*Pencarrow Gardens, Bodmin.*

## INDOOR GARDEN.

### CLIMBING PLANTS.

IT matters very little whether these be occupants of the plant stove, greenhouse, or conservatory at this season of the year, they all require diligent attention. In some instances it may be necessary to free them from mealy bug, scale, and other insect pests with which occasionally they become infested. Pruning also is necessary, that is to say, a great portion of the weak superfluous growth should be cut out. Among the climbers of which the growth occasionally gets overcrowded, is *Stephanotis floribunda*, *Tacsonia Van Volxemi*, *Schubertia grandiflora*, *Hoya bella*, *Lapageria alba* and *rosea*, *Cobaea scandens*, *Clematis indivisa*, and others of a similar character. *Allamandas*, *Bougainvilleas*, *Habrothamnus*, *Plumbagos*, and climbers of this kind require to be pruned well back, that is to say, cut back the growths made the previous season to within one or two eyes of their base, and encourage the production of shoots that will be strong and floriferous during the following season. Consideration should be given to *Clerodendron balfourianum*, as the shoots of this should not be spurred back as is recommended for *Bougainvilleas*, &c. A few weak growths may be cut out altogether, and the weak points of others be shortened back; but as they flower mainly from strong, well-ripened growths, the object should be to encourage this, and to utilise it to advantage.

#### PALMS.

Generally these plants are so much in request for house decoration that, at this season of the year—unless more than ordinary care be bestowed upon them—they suffer to such an extent that, whatever after attention is given they seldom recover from the seriousness of the check received. During the present more than any other season of the year Palms, especially *Kentias*, *Arecas*, and *Seaforthias*, will appreciate, and respond to, the advantages of a little extra warmth, with plenty of syringing. Chemically prepared manures, either solid or in liquid, are applied to stimulate growth, but preferable, perhaps, is liquid made from sheep manure, together with an occasional dose of soot water, weak doses in every instance being recommended. Occasionally syringe the plants well with soft soap water as a means of checking the further spread of scale, as well as loosening any that already may have fixed itself upon the fronds.

#### TREE CARNATIONS.

For blooming from autumn until the spring of the following year few plants are so useful as these. The one thing necessary to produce a profusion of flowers is to have good plants, and to do this their propagation is advised to be commenced as soon as possible. Methods of propagation to suit convenience will naturally require to be considered, but there can be little doubt as to the advantage of inserting four or five cuttings around the sides of 3-inch pots, in a compost of equal parts of loam, leaf-soil, and sand, peat being added only when the loam is of a clay-like nature. Plunge the cutting pots in cocoa-nut fibre refuse in the propagating frame, which keep close, and the soil in the pots moderately moist. In beds of sand, heated from hot-water pipes below, cuttings by thousands can be inserted, but when rooted and afterwards lifted for potting up, they seldom commence rooting so freely and so early as do those that are propagated in pots in the compost recommended. J. P. LEADBETTER.

*The Gardens, Tranby Croft, Hull.*

**KITCHEN GARDEN.**

THE weather in this district is still such as retards kitchen garden operations, several degrees of frost being registered every morning, and thawing towards noon. This makes it impossible to do any digging, planting, or operations of that nature. Where the climatic conditions are not so troublesome attention might be turned to the making of a new plantation of Horse-radish. In many gardens the cultivation of this vegetable is neglected, the roots being left to their own devices year after year. By lifting every third season much finer roots are produced, and are sure to be appreciated when they are sent to the kitchen. The ground should be deeply trenched and a liberal supply of good manure placed at least a foot from the top. The strongest crowns should be selected and cut into lengths about 6 inches long. Side roots on the sets should be rubbed off, and the sets planted at least 1 foot deep.

**RHUBARB.**

For new plantations the ground may be treated as advised above, choosing a plot which has not grown this vegetable for some years. After planting a good mulching should be given, and none of the stalks should be pulled the first season. Where heated pits are available, they may now be got ready for the forcing of early vegetables—Carrots, Turnips, Radishes, &c. Heated pits are now a necessary equipment to every well-appointed garden, entailing as they do much less labour than the old system of hot-beds. The earliest Peas and Potatoes are here grown in pots in the fruit houses, and are succeeded by those now being sown and planted in the pits.

**TURNIPS.**

A sowing of an early variety should be made at once, Early Milan being as good as any. Sow rather thinly broadcast, having the soil raised to about 8 inches from the glass.

**CARROTS.**

These much-prized roots may be also sown now on soil raised as advised for Turnips. Several inches of sea sand should be spread on the surface and forked in. The seeds may be sown much thicker than Turnips, and a slight draw with a rake will be a sufficient covering. The pits to start with should be kept at a temperature of 50°. If the soil is at all dry a slight watering may be given, as this will ensure quicker germination.

**PARSLEYS.**

Owing to the excessive wet during the autumn months this has kept badly in many gardens, supplies being drawn entirely from plants in frames. Should the stock be running short plants may be lifted and put thickly into boxes, and if placed in heat will soon start into growth. A sowing should also be made now, and placed in a temperature of 60°. As soon as the plants can be handled they may be pricked into a warm pit. A supply from this sowing should also be available for planting out in April on a warm border that has been deeply dug and manured.

THOMAS HAY.

*Hopetoun House Gardens, N. B.*

**CHRYSANTHEMUMS.**

**TREATMENT OF CUTTINGS.**

THE majority of the cuttings which were put in the propagating pits early in the month will soon be sufficiently rooted to remove to a cooler and more airy position. Any which have failed to strike or have not made a good start should be discarded and others put in to take their place. I have always found the best results from those plants which start away freely from the first and are never allowed to receive any severe check throughout their season of growth, consequently unless any particular variety is scarce all doubtful ones are at once discarded and replaced by the best cuttings at command. The number of each variety to grow will have to be determined before too late in the season. Much, of course, will depend on the particular use for which they are likely to be required. If it is the intention of the grower to enter into competition this is a matter of importance,

and as many of the leading societies are now offering valuable prizes for a given number of blooms, to be arranged in vases, a goodly number of each sort must be grown to ensure each individual bloom being of the high standard of excellence which is necessary if high honours are to be won. As I have often previously advised it is better to grow several of the most approved sorts rather than a large number and one or two of a kind; and even when a collection is grown for home use only, a much better display can be made when the best only, and several of these, are grown.

**SPECIMEN PLANTS.**

If cuttings were inserted early in December last, as should have been the case, these will now be well rooted, and require potting on into 3-inch or 4-inch pots. They will require to be grown on in a gentle heat for some time yet, as it is always essential to build up the foundation of the plants as early in the year as possible, but at the same time undue forcing must be strictly guarded against. A light position near the glass should be given, and after the regulated height of stem has been assured the points should be pinched out to induce them to break.

**BORDER VARIETIES.**

Those which have done duty in the open ground during the past summer and autumn should now be lifted and potted up, if not already done. Many of these varieties will, of course, succeed fairly well if left in the ground through the winter, but if the best results are to be obtained the above method must be resorted to. For this purpose clean, well-drained 3-inch pots should be used, and a suitable compost will consist of loam and leaf-soil in equal proportions passed through a three-eighths of an inch mesh sieve, with sufficient road or silver

sand to keep the whole in a porous state. When dividing the plants select only the best pieces with healthy young shoots round them. Cut the roots back so that they may be easily placed in the pots, and pot moderately firm. As one sort is completed correctly label each pot and sprinkle a little silver sand over the surface. A cold frame will be the most suitable place to arrange them in for the winter, and admit air freely on all favourable occasions, removing the lights entirely on bright, fine days. Thoroughly cover and protect at night during severe weather, and any plants left in the ground should have cinder ashes heaped round the stools. E. BECKETT.  
*Elstree, Herts.*

**ORCHIDS.**

**MILTONIA.**

NEW roots are now being emitted from most of those that flower in the early autumn, such as *M. Clowesii*, *M. candida*, *M. spectabilis*, *M. Regnelli* and its many beautiful forms, and the hybrids of the above species. Any repotting or dividing necessary this season should be taken in hand, and those not requiring potting should have the

surface material removed, so that the young roots may have fresh compost to take hold of. A compost made up of two-fifths good fibrous peat, two-fifths clean live sphagnum (both well chopped), and one-fifth good leaf-soil, the whole being well mixed together with a little coarse sand, answers well. Pots should be the receptacles used, half filling them with chopped rhizomes that have been prepared as previously advised. Those plants that have many old pseudo-hubs should have all removed, with the exception of two behind the leading bulb. The most favourable time to cut away and reshape one's plants is when they are being repotted. The compost should be made moderately firm and kept below the rim of the pot to allow of a surfacing of chopped sphagnum. The intermediate house provides suitable quarters for them all the year. Water should be carefully applied till the new roots have taken a good hold of the compost, then they will take water freely till the completion of growth.

**PROPAGATION.**

Miltonias can be increased by cutting away the leading bulbs just when new roots are being thrown out, carefully working out with a pointed bone, without unduly disturbing the old plant, any roots attached that may have entered the compost. The young plant should then be potted in as small a pot as possible and kept fairly dry at the roots for some time. A slight spray overhead daily will be very beneficial to them. After the leading bulb has been cut away the old plant should be kept dry till it makes a new lead, when it should be repotted. This rejuvenation often gives fresh life to plants that were fast deteriorating. When there is a desire to increase the stock, this method is far quicker than that of propagating

ROSE FLORA ON GARDEN HOUSE BY BOLD GROUPING OF CAMPANULA PERSICIFOLIA AND OTHER FLOWERS. (See page 58.)

from the back pseudo-bulbs. I have had fine bulbs produced from the back portion the first year that have flowered well, and the front part with care will often develop a finer growth than the preceding one.

#### MILTONIA VEXILLARIA.

This summer-flowering Orchid, now growing freely, will still require watering with great discretion, increasing the supply as the days lengthen and light becomes stronger. Any plants that were potted in the past summer into small pots may now, if the growth is satisfactory, be given a larger pot, using the same material as advised above. The greatest care should be exercised in repotting not to damage any roots. The dreaded spot oftentimes seen on this variety generally arises from injudicious watering during the short days and not enough ventilation. It is well suited in such a temperature as the Cattleya house affords. A strict watch should be kept for thrip, which will in a few days disfigure the growth and make it an unsightly object rather than one of beauty. W. P. BOUND.

*Gatton Park Gardens, Reigate.*

## THE FRUIT GARDEN.

### APPLE ADAMS' PEARMAIN.

**M**OST people have a desire in gardening matters to run after that which is new, whether in fruit or flowers, simply because of the charm of novelty, and not always because the new product is better than the old. This natural desire is most commendable, and a potent influence in urging men on to greater triumphs. At the same time, this desire, if unrestrained, is apt occasionally to do harm, by causing old and sterling varieties to be neglected and lost sight of. This is more or less the case with the subject of this note—Apple Adams' Pearmain. Years ago, when selecting late dessert Apples, this one was scarcely ever left out of even the most limited collection. I am of opinion that it should still be included in the best twelve dessert sorts. It is large in size, handsome in shape (a true Pearmain), and the colour is most pleasing—a golden skin, covered with a delicate russet on the shaded side. It is one of our most prolific bearers, even in a young state, and the flavour is excellent. Its best season is from January to March. O. THOMAS.

### GRADING AND PACKING FRUIT AND VEGETABLES.

THE Board of Agriculture have just issued the following important leaflet on the above subject:—

Intensive cultivation has been carried in many places to a high pitch of excellence, and British horticulturists pride themselves, justly, upon their skill as producers. Admirable and necessary as the highest cultivation must always be, yet something more is required to ensure complete commercial success, namely, the conveyance of the produce in the best possible style to the market or to the consumer. It is at this point, too, many fail, and a material proportion of unprofitable sales is mainly attributable to neglect in presenting goods in the most satisfactory manner. Proofs of this defect are evident in every British market, and commonly the produce of the home grower may be seen in direct contrast with that of his foreign competitors, to the conspicuous disadvantage of the former. It is the purpose of the following notes to give some directions that, with the exercise of intelligence in carrying them out, may assist in improving the selling value of both fruits and vegetables as produced in this country.

To aid in grading fruits to the best advantage it must be assumed that the preliminaries of successful cultivation have received due attention. The selection of the best varieties, suitable sites

and soils, with every possible care in protecting the trees from attacks of insects and diseases, demand the cultivator's utmost skill and unceasing watchfulness. Finally, in preparing for the actual work of grading, the method and time of gathering should receive the strictest attention, or much of the other labour will be reduced in value. It is not sufficiently recognised how readily all fruits are injured by rough handling. Even hard, unripe Apples and Pears are soon bruised, and not only do these marks show as serious defects in the appearance of the fruits, but the keeping qualities are also affected.

One general rule is applicable to all fruits, and that is, they should never, if it can be avoided, be gathered when they are wet, especially if they have to be packed for sending a long distance.

#### IN PREPARATION FOR SORTING.

The fruits should be taken and carefully spread on a table or bench, which may slightly slope to the front, and should be of a convenient height for the packer to stand at. The soft fruits must be conveyed to the sorting room in shallow trays or baskets, so that they can be graded direct without turning them out. When experienced hands are employed some degree of sorting can be done at the time of gathering, thus saving further handling or removal of the fruits, and the grower will in every case endeavour to reduce this to the minimum.

Several matters have to be considered in the actual work of grading, and an intimate knowledge of the characteristics of varieties is essential to the best results. The effects of seasons on large crops also demand attention; for the second grade of one crop might rank as the first of another. It is impossible to lay down a rule that would constitute a standard equally reliable under all conditions, but a general idea can be given of the relative values of different grades under similar circumstances.

The points of importance in classifying the best fruits are: (1) Freedom from injuries and blemishes. (2) Good size and even form. (3) Colour. (4) High quality with ripeness.

The first two are essential to all high-class fruits, and no defective, distorted, or undersized samples should be allowed in the leading grades of any kind.

The third quality is a special one, which always possesses a marked value in fruits for dessert, and even amongst some used for cooking or preserving, as in Apples, Red Currants, Raspberries, and Strawberries, for example. A richly-coloured sample, though only of moderate size, if free from defects, will often possess a higher market value than larger and duller fruits. Cox's Orange Pippin, for instance, if sold in two grades, one large and dull or greenish yellow, and the other a size smaller, but in its best colour, will command the larger price for the latter; and this is true of many other fruits where colour is a characteristic that is sometimes deficient in the larger sizes.

As regards the fourth point, mere size may also be a secondary consideration, provided the fruits are choice, in perfect condition for immediate use, and free from defects. This especially concerns small packages of dessert fruits, such as the finest Pears, Plums of the Greengage type, ripe Cherries, Peaches, and Nectarines. A special market must be at command for such samples, or they should be sent direct to the consumers or retailers.

The bulk of fruit grading will, however, be mainly concerned with variations in size, provided the essentials of good form and freedom from defects be secured. It is of the utmost importance to ensure that each grade be as uniform throughout as close attention can accomplish, and then the full value of the work is most likely to be obtained.

#### A QUICK EYE AND SOME PRACTICE

under good guidance soon enable a packer to select the various sizes in a uniform manner. Apples in particular can be readily graded into several sizes according to the variety and the crop. Occasionally four well marked grades may be obtained, in other instances perhaps three are secured, and sometimes

only two are obtainable. The difference of a quarter of an inch in diameter will constitute a well marked grade. An American association has adopted as the minimum standard for first grade Apples of the largest types  $2\frac{1}{2}$  inches diameter; while for the smaller types  $2\frac{1}{4}$  inches is the minimum diameter for first grade fruits; in each case a quarter of an inch is allowed between the firsts and seconds. In practice it is found almost impossible to adhere to such exact grading; the general standard and range in size of the crop or variety must be judged, and the graduation founded upon this. These remarks especially refer to Apples for cooking, or dessert Apples equally well coloured, but what has been already said about the value of colour must be remembered, and a special grade selected of uniform size where there is a proportion of larger fruits deficient in that respect.

Most of the details regarding Apples are also appropriate to the grading of Pears, but as a larger proportion of these are used for eating than cooking, they are more adapted for disposal in small packages, and hence repay the greatest attention in uniform grading. Several qualities can usually be obtained from one crop, and it generally pays best to sell in two or three grades, only those rejected in the selecting process being disposed of in bulk. Even when large crops from old orchard trees are being dealt with, a few dozen of the finest fruits carefully packed will help to raise the total returns considerably.

Stone fruits may be selected in various grades. Plums for cooking can thus be sorted into two or three grades, the largest fruit commanding the best market. A good medium size is in demand for bottling, and the smaller sizes are utilised in ordinary cooking or preserving. Dessert Plums and Cherries are readily graduated on the same method, the finest in boxes or small packages, and the others in bulk.

Soft fruits, such as Strawberries and Raspberries, are worthy of equal care, the former being sorted into at least two grades and sometimes into more. The best are placed in punnets, the next in small boxes, and a third grade can be sold in boxes or baskets holding from 6lb. to 12lb. Raspberries may be conveniently divided into two qualities whenever a special sale can be commanded for the best fruits either in punnets or small boxes.

Nearly all other fruits also admit of some grading, even though it be only to the extent of excluding defective and malformed specimens; the results yield a satisfactory reward for the labour and expense.

#### GRADING AND PACKING VEGETABLES.

The benefits derivable from careful and systematic grading are by no means confined to fruits, as vegetables also afford considerable encouragement to those who strive to make the most of them in the same direction. Especially is this the case with root crops, though in a general way the sorting adopted is of a very rough character. Potatoes, for example, are usually picked up in three sizes, the large tubers for sale, the seconds or sets, and the small tubers to be used as food for stock. The large size should be again sorted into two or three grades; it is with them as with Apples, a comparatively small proportion of coarse irregular tubers spoils the appearance of a large consignment. Even shape and uniformity of sample possess a distinct market value, and a medium-sized Potato having these characteristics, together with good quality, will bring a better return than huge distorted tubers of which size is the only recommendation. If an extra 6d. per bushel, or £1 per ton can be secured by such care it often means, with a good crop, sufficient clear gain to more than pay the expenses of cultivation.

A distinction can be made between the best or earliest Turnips and Carrots and the ordinary quality or crop in bulk, by marketing the former in bunches, while the latter are sent in bags or baskets. Onions, too, can be graded in several ways, the best being bunched or made into "ropes," while smaller sizes are sold loose, the smallest ranking as pickling Onions. It is always advisable to have several sizes, each sample fairly uniform, as some buyers have a preference for medium size

bulbs and others for large ones. In selling small quantities by weight the retailers have a difficulty with the largest Onions, and usually find the medium size more convenient. If roots are prepared for sale by being thoroughly cleaned it is a great help, and in any case wherever grading is followed all the best qualities should be so treated, or the chief part of the labour will be nullified.

Peas and Beans should always be graded. Yet this is seldom done by the grower, and, as with many other vegetables, it is usually left to the retailer. Large, well-filled pods of the former are always in demand, and if the colour is good their value is enhanced. But they are too often gathered without due care, and a number of insufficiently developed pods materially lower the value of the whole, while reducing future gatherings. Two or three grades of Peas can be readily formed, according to the condition of the crop and the varieties, some being much more even croppers than others. In supplying consumers direct daily or at regular intervals, it is now becoming the practice to shell the Peas, grade them by means of sieves, and consign to the purchaser in small boxes. Dwarf kidney Beans and Scarlet Runners can be

This refers both to quality, crop, and height, and in town gardens I think the latter most important, as by obtaining an equally heavy crop from a dwarfier haulm is a gain in the right direction. Take the early sorts first. A variety that stands cold—an important point in heavy soils—is Veitch's Acme. It is a new variety that will be found valuable for late May or early June supplies. Acme is dwarf (3 feet), and has a medium-sized pod containing eight to ten Peas of a deep green colour. When on trial at Chiswick it was considered a distinct advance. For years Chelsea Gem has held its own, and the new one is an improvement and the result of crossing a very dwarf early with Stratagem. All growers know what a splendid variety the last-named proved for many years. I now come to a very different Pea—Sutton's Early Giant. This is well named for such an early variety; it is a giant, and its crop is splendid. So far it has proved one of the most prolific varieties. Sown early in February it was ready on May 30, in a bad season; its height is 3 feet to 4 feet, but we top our

height, and very prolific. In the next division such sterling varieties as Carter's Daisy will need few words as regards its crop, quality, and size. It is one of the best of this section, and is so well known that I need not dwell upon its merits. The growth is robust, and the quality is excellent. Danby Stratagem is also another Pea that Messrs. Carter have selected from the original Stratagem; it is very reliable, 2 feet to 3 feet, and has a full Marrow flavour, whilst it is also a great cropper. In the midseason section there is no lack of quality. We have such varieties as Prize-winner, Dwarf Defiance, Centenary Marrowfat, and the new Edwin Beckett (sent out by Messrs. Cutbush), a grand Pea both for crop, quality, and quantity. To this list may be added Veitch's Maincrop, Autocrat (an older variety), and such sorts for late use as Carter's Model, Telephone, Michaelmas, and Sutton's Prolific Marrow, Peerless, and Royal Jubilee.

POTATOES.—At a time when fabulous prices are given for new varieties it is dangerous to criticise. I am unable to note the cooking or cropping qualities of the new Northern Star or Eldorado, but they sell well, and should be an acquisition if the vigorous constitution claimed for them is lasting. Discovery I have more knowledge of, and I have been pleased with its perfect freedom from disease and its splendid table quality, but we have others well worth retaining, such as May Queen, a grand first early, and one I shall plant more largely this season. To this may with advantage be added Ringleader and Ninety-fold, and, so far as regards weight of crop for June supplies, it has no rival. Another fine tuber is Ideal. This may be classed as an improved Windsor Castle, and the newer Centenary promises to be a valuable introduction. Of older varieties, Satisfaction, Triumph, and Reliance are all excellent and not fastidious as to soil or situation. A new late Potato, Evergood, is well spoken of. So far I have not grown it. We grow large quantities of Syon House for late use.

CABBAGE is one of the most important vegetables, and may be had good every day in the year. Of course, the earliest Cabbage finds the most favour, and rightly so, as these come in when good tender vegetables are scarce. For spring cutting such varieties as Earliest, April, and Flower of Spring are invaluable. Then there is the excellent Ellam's Early Dwarf, Wheeler's Imperial, and Mein's No. 1, older kinds, but difficult to beat for summer use; Tender and True, Veitch's Matchless, Sutton's Favourite and Little Gem, the Coleworts for early autumn, and for winter St. Martin's—a cross between the last-named and Christmas Drumhead—with such additions as St. John's Day and others.

CAULIFLOWERS AND BROCCOLI are so well known that it may appear out of place to write about them. For early supplies it is difficult to beat Snowball, Veitch's Forcing, and Sutton's First Crop, and for later use Mont Blanc. Purity and Pearl are invaluable, with such varieties as Walcheren and Autumn Giant later.

BEANS are always favourites, and mention should be made of Hackwood Park Success, a Bean of the Runner type. In Broad Beans Sutton's Green Giant is a magnificent pod, and of splendid quality. Of Dwarf Beans Messrs. Cutbush have a grand Bean, both as regards crop, quality, and length of season, in their new Bountiful.

CUCUMBERS are always favourites, and the newer varieties, such as Every Day and Unique, are worth a trial. To these may be added Peerless, Satisfaction, and the old Veitch's Telegraph.

APPLE ADAMS' PEARMAIN. (Two-thirds natural size.)

graded by selecting the long, straight, and even pods for the best samples, in smaller quantities, the bulk going for sale in bushel or half-bushel baskets. (To be continued.)

## THE KITCHEN GARDEN.

### SOME OF THE NEWER VEGETABLES FOR 1904.

**K**ITCHEN gardeners will now be making up the list for the coming season, and it is not so difficult as formerly to make a good selection, as our leading seed houses issue catalogues which may be regarded as quite trustworthy guides. I think that in the present day fewer objections are made to the newer things, which is not to be wondered at, as with increased interest in vegetable culture, greater publicity, and rapid means of communication, a good thing is soon known.

PEAS.—For the past fifteen years I have kept a close watch on the new varieties sent to Chiswick for trial. I have also seen others, and a splendid advance must be recorded.

plants at 3 feet to induce branching out. In due order such Peas as Sutton's Duchess of York and Ideal would follow next, but there are different soils to deal with and northern latitudes. Here the hardier Harbinger will be found most valuable; it is dwarf and very early, so that it may be sown later and then give an early crop in gardens limited in size. Peas having, say, a haulm of 12 inches are most useful. I occasionally meet with growers who still grow American Wonder, but, though of the same shape, the pods are broader, longer, and equal in earliness, and the flavour is excellent. Duchess of York is a variety well worth a trial; it is 3 feet high, and one of the finest of the early class. The flavour is full and rich, and the variety is a little later than the older but grand May Queen, which is valuable for early or mid-June supplies. Ideal was sent out in 1901, and Messrs. Sutton described it as of high table quality. It is certainly a delicious Pea; the plant crops heavily, and it is well worth a place in any garden. Little Marvel, a variety which has had two high awards, is valuable in small gardens or for pot or frame culture. It is scarcely more than 12 inches in

There is no lack of good variety in roots. Carter's Crimson Ball Beet is excellent, and of longer roots the newer Blood Red is very fine. A trial should be given the new Intermediate Sutton Parsnip, a splendid introduction, also the Sutton Vegetable Marrow, a beautiful oval fruit for exhibition.

TOMATOES are always to the front, as they are much more grown than formerly. The new Winter Beauty is a great gain as regards earliness, but there should be a trial of the yellow fruits, such as Golden Jubilee, a variety of good flavour.

SPINACH.—This popular vegetable has been improved of late. The Carter Spinach is a splendid addition, and there are other vegetables I hope to note in THE GARDEN later.

G. WYTHES.

## CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

### ORCHIDS IN FIELDS AND FORESTS.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—In THE GARDEN of the 9th inst. there appeared a note on the great abundance of Orchis Morio. This Orchis is not very common, not so much so as either *O. mascula*, the earliest flowered, or *O. maculata*, both of which are capable of making a far greater display of colour than *O. Morio*, with its greenish veined upper petals, although the plants frequently occur in greater abundance. In some districts albino varieties are much less common among *O. Morio* than in the other two mentioned, while in other parts the reverse is the case.

A small meadow in the east of England, surrounded for miles by arable land on every side, was very conspicuous every spring for its display of *O. Morio*, among which grew a few *O. pyramidalis*; but during the four years the meadow was under the writer's notice the plants showed no signs of the disappearing trick which appears to haunt some breadths of it in certain districts. When moist pasture land purpled with Orchises is drained, these plants find it a difficult task in one season to flower, to form a new tuber, and to mature the numerous capsules, each of which contains thousands of seeds. Such a plant may not throw up flowers the succeeding year, but may devote its energy to forming another tuber that will certainly flower the next spring. It is the formation of each succeeding tuber by the side of the last that gives these Orchises the name of "Walking Plants." It is a distinct way of travelling, though certainly not a quick one.

Far more effectual as regards distribution than any "walking" antics are their widely distributed seeds, so light that they could easily be established over the countryside. In the meadow above mentioned, which did not exceed four acres in size, and was bounded by arable land, and beyond this by woods, few of the many millions of seeds, save those that germinated among the grass that surrounded them, could have found a growing place for miles around, for in woods the meadow species do not grow. In Scotland several native Orchids may be met with in great abundance. On the meadows around Loch Tay and other districts *Habenaria bifolia* and the larger *H. chlorantha* (the Butterfly Orchis) are extremely plentiful, and give way on the higher sub-alpine terraces to the Globe Flower or *Trollius europæus*. These *Habenarias* are among the most beautiful of European Orchids, and are well worth growing in the garden, choosing a half-shaded position. Wild it grows well in shade and sun, but the tallest of the white fragrant spikes are found in moist loam and slight shade. With the above also grows *H. conopsea*, or *Gymnadenia*, while the green *H. viridis* (the Frog Orchis), with shorter stems, forms dot plants

among the larger and more ornamental Orchises. Often the finest specimens of the last two are found on drier ground than *H. bifolia* favours, and in gardens *H. conopsea* should be planted in the sun, and lime rubbish mixed with the soil if heavy.

On walking through the grass, the air deliciously fragrant with the scent of the beautiful mauve-pink flowers of this Orchid, one most exquisite white form was seen, and only one, though the white-flowered *O. maculata alba* was frequent. The rarity of this white form is noticed in "British Orchids." A few Scottish woods are famed for a little Orchid, which delights in loose soil of Pine needles and moss. In some localities *Goodyera repens* is very plentiful, suggesting at first a *Pyrola*, for its leaves are evergreen, and the flowers, on splendid spikes, are in full beauty in July. The *Goodyera* is more easily established than many of the tuberous kinds, and may be naturalised in woods of Pines. For garden culture this species is surpassed by the Japanese *G. macrantha* and the American *G. pubescens*, which possess nicely white veined leaves, and are very suitable for shaded rockeries in peat and leaf-mould if slugs are kept off them. Of course, all native Orchids are usually lifted at the wrong time, that is, when they are flowering. If their roots are disturbed then they seldom succeed, but many prevent this by taking a good bit of the soil and grass away with each root, and carefully planting in similar material very firmly pressed in the garden, where the above thrive well.

None of the Orchises usually gathered can compare with *O. maculata superba*, a variety seldom found wild except in very rich soils. Big as it is, it improves with garden culture, forming fine clumps, which in flower suggest a good *Liatris*. Spikes received from Ireland measured 18 inches in length, and 12 inches of their stems were thickly clothed with pale purple flowers. The leaves are also ornamental, and are spotted with purple. It produces the largest flowers in rich loam, in a slightly shaded position. This grand Orchis is yet known in some gardens as Miss Hope's Orchid; it was first brought over from Ireland by that late plant enthusiast of Edinburgh. This and several *Cypripediums*, fortunately better known, have proved the best Orchids as open air plants in this country.

### APPLES.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—An excellent note on Apples appears in THE GARDEN, page 414. Here in British Columbia it is very disheartening exposing Apple trees for sale. So many people come from different parts of the world, and many of them will not take advice from those that have experience. For instance, I had an order for 400 Princess Louise Apple from a perfect stranger in the country. The variety, if there is one of that name, has never been tested here so far as I can find out. Most of these people that give outlandish orders have read about or have been acquainted with certain varieties that are doing well in some other part of the world, and they think that they should do well here. This year there has been a great call for Northern Spy, a good Apple, but it takes from ten to fifteen years to come into bearing on this island, and is tardy in most localities. I have a neighbour who is a fruit grower, and he has a lot of Northern Spy about fourteen years old, and only one of them has borne a few Apples. The same man had a lot of Greening, but he never got a paying crop from them. They were planted on an eastern aspect, thin but rich soil, with a slightly gravel subsoil. I have some trees that I propagated at the same time and from the same parent tree, which for the last three years have given me from nine to sixteen boxes of fruit per tree. They are planted on a south-west aspect on a rich, deep black soil, with sandy subsoil and clay below.

If a certain variety does well in a certain season there is sure to be a demand for it, no matter if it had been a failure for several years previously; then, if it fails the next season, the nurseryman will be left with a large stock on hand if he has

started to propagate the variety extensively. Planters should be satisfied to plant good tested varieties that do well in most localities, and especially in the one they intend to live in. With me all varieties that I have tested do well with the exception of Northern Spy and *Esopus Spitzenburg*, but planters for market must look out for good selling varieties. A box of Alexanders will be bought here before a box of Newtown Pippin, so you see the difference here and in London, England. If we had an Apple that is as large as Emperor Alexander and as showy, also a late keeper, it would take well here providing it would grow well. English varieties do with me even better than American. We have a native Crab (*Pyrus rivularis*) that is very pretty. It grows from 10 feet to 20 feet high, and its fruit is about the size of Black Currants; birds are very fond of it.

GEORGE A. KNIGHT.

*Mount Tolmie Nursery, Victoria, British Columbia.*

P.S.—A box of Apples runs from 40lb. to 50lb., according to the variety, some weighing heavier than others. Apples are usually grown on free stocks here.

### RAINFALL IN 1903.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—The measuring and recording of British rainfall is now so universally adopted that there must be a very large number of your readers interested. I therefore send you a table showing the monthly records in these gardens for comparison with other readers' measurements. It will be observed that both the number of wet days and the total exceed those from Mr. Sinclair, given on page 30, from Hampton Manor, though this is not considered a wet district at all. This amount exceeds our average of the past eight years by 18.98 inches, truly a remarkable and undesirable excess. Maximum temperature (July 11), 90°; minimum (January 15), 12°. There were sixty-two frosts during the year, with so many ill-remembered ones in April and May, carrying out such complete devastation in garden and Orchard. October seems to have afforded the most phenomenal rainfall on record, not in one district or county, but universally. It is curious to note how varied are the measurements even of a day's rain at different stations; even situated, it may be, but a mile or two apart, there is the same marked variability of register. Some good comes even from this gloomy record, and is found in the strengthened state of the water supply from both deep and surface springs. For a long time the dearth of water, even out of the summer season, has been an oft-repeated cry.

## NOTES FROM THE MARKETS.

### COVENT GARDEN.

THERE is a good deal of change both in the supplies and the demands during the past few years. The cold storage brought about a great reform, and since we have had Lily of the Valley, Lilies, and *Spiraea* all the year through, some of the older favourites find less favour. The old double white

Chinese Primula was formerly a most profitable winter-flowering plant, and though it may yet be seen in market it is no longer in great demand, and several of the growers who used to grow it in large quantities have given it up entirely. The single Primulas are no longer a profitable crop; they have been on the market for some weeks past, but there is little demand. I lately noticed a fine lot of plants on a costermonger's barrow, which in itself was good evidence that the market value was very low. A good many well-flowered plants are now coming in in 3-inch pots. There are also some of the stellata type, both cut and in pots, but these attract little attention. A good many of the small flowering plants are now substituted by cut flowers and cut foliage. Good cut foliage may often be used with greater effect than pot plants. When I first saw the late Mr. Green of Crawford Street cut down beautiful plants of *Aralia Veitchii*, *gracillima*, and *elegantissima*, for which he was paying 3s. 6d. each, I thought it a great sacrifice, but when seeing them used in the centre of fancy bowls with a few choice flowers round them I recognised their value for the purpose. I have seen other choice foliage used in the same way, and at the present time choice cut foliage is much in demand. Another old favourite which is not so much used as formerly is the Maiden-hair Fern. *Asparagus plumosus nanus* has taken its place to a great extent, but other suitable foliage is also substituted. Of course there is still some demand for the Maiden-hair, and it is doubtful if it will ever be superseded for some purposes. Just at the present time really good Maiden-hair Fern would sell well, but there is plenty of second quality on the market. The leaves of *Cycas revoluta* are another comparatively modern innovation, being much used for the ground-work in funeral emblems. There is a good supply of these now coming into the market. English-grown *Smilax* may now be had pretty well all the year through. *Asparagus Sprengeri* is now being much used for green, yet it hardly finds as much favour as it deserves, for in addition to the quality of lasting well, it works in with flowers with great advantage.

Of general market trade there is little to record, except that everything continues very quiet. The *Chrysanthemum* are beginning to fall off, but Dutch and other bulbs are coming in in quantities to take their place. The Paper White and other *Polyanthus Narcissi* are plentiful, and we shall soon have *Daffodils* in abundance.

A. HEMSLEY.

## MISCELLANEOUS.

### RESURRECTION PLANTS.

REFERRING to Mr. A. Hemsley's interesting note on the above (vol. lxiv., page 371), *Selaginella lepidophylla* differs from the other examples cited in retaining not only its power of expansion after prolonged drought, but also its vitality unimpaired. Some years ago, passing through Texas by train, I noticed several children on the side of one of the stations who were selling little baskets of the local Cacti and *Selaginella lepidophylla*, the latter in the form of dry brown incurved masses, roughly resembling an incurved *Chrysanthemum*, but quite dry, hard, and brittle. As I recognised the plant I bought several and put them into my portmanteau to take home as curios. Quite six weeks later I came across them when unpacking, and dropped them overnight into a pail of water. Next morning I was delighted to find as many bright green and perfectly fresh rosettes which, when potted up and installed in my fernery, resumed, I cannot say started, growth as if nothing had happened to them. One of them I saw recently in good condition at Wanstead in possession of a friend to whom I gave it at the time. These plants present a very curious case of adaptation of a moisture-loving genus to conditions of severe and prolonged drought. During the rainy season they thrive in the chinks of rocks and similar habitats, but when the dry season sets in

each frond curls inwards from the tip towards the centre, presenting its brown, thickly-scaled under surface to view, and eventually forms a sort of ball, as above described. This, rooted up by strong winds, is blown for months about the prairie, where the children collect them for sale as aforesaid. When the rains are resumed they simply root where they lie, which is naturally usually in such hollows as they have drifted into. How long they might be kept in a dry state I cannot say, but in this case it was probably two months between the time of gathering and resuscitating, and considerably more since they first dried up and got adrift. We need not, however, go abroad for resurrection plants since our common *Ceterach officinarum* forms a good rival to the *Selaginella* in its drought-resisting capacity, and on similar lines. I once collected a plant in Asia Minor which I wrapped in an envelope and put into a breast pocket, whence it was unearthed, so to speak, four months later. The fronds were curled in with the thick brown scales outwards, and apparently as dry as tinder, yet dropped into water overnight it was perfectly green and alive next morning, and when planted resumed growth at once. This Fern has a fancy for the sunny sides of rocks and old walls, and in very dry summers we may see it in its brown and shrivelled condition looking as dead as dead can be, and yet capable of reviving or resurrecting when moister conditions permit. Numerous exotic Ferns of the *Notholaena* and *Cheilanthes* description are similarly gifted, and years ago Mr. Loder, now Sir G. Loder, sent the writer a plant (*N. Fendleri*) which had been posted to him dry from the United States, and was none the worse for the ordeal when soaked and potted up. It is noteworthy that dense dorsal scales, either white or brown, are present in all cases as a protection.

CHAS. T. DRUERY, F.L.S., V.M.H.

### FRENCH CAPERS.

As a food or culinary adjunct Capers are much used on the Continent, also in England and America. The commercial product known as Capers are simply the undeveloped flower-buds of a bush which grows in Southern Europe and in the North of Africa. The species that is common to Europe, and is cultivated in Spain, Italy, and the departments *du midi* of France is *Capparis spinosa*, the Egyptian Caper is *C. aegyptiaca*, the Caper of Greece is *C. rupestris*, and the Caper of Barbary or Northern Africa is *C. Fontanesii*. In France, especially in the district of Provence, the Caper bush thrives on chalky soils, and grows well when planted on rising ground well exposed to the sun. Poor dry soils are also utilised, but experience shows that better results are obtained when the quality of the soil is good. The Caper bushes are propagated by cuttings of about 10 inches in length, which are planted in some selected place that is considered as being especially favourable for their striking. Experience has shown that it is best to plant the cuttings in a soil somewhat akin to that into which they will be finally transplanted. By this method, though not more than 20 per cent. usually survives, yet good results are obtained on transplantation. On the other hand, if cuttings are planted in a rich moist nursery, they will nearly all grow; but when the plants are transplanted into poor soil their growth is arrested to such an extent that the effect is felt for years.

Planting out is done in spring time, the ground having been previously well ploughed and manured, and the bushes are placed at a distance of about 8 feet from each other. They yield a small crop the first year, but in two or three years they are in full bearing. Each year upon the approach of winter every branch is cut down to a length of 8 inches to 10 inches, and then the earth is hoed in a heap over the entire bush in order to preserve it from the effects of frost, and thus treated the bushes will stand a temperature of 10° to 12° Centigrade. In March the earth is removed, and the branches are again cut closely to the trunk, which is left bare, the branches now cut being used as cuttings. At the same time the ground is ploughed and manured, and from time to time, till

June or July, it is hoed and weeded. By July the bushes are fully grown, and their branches cover nearly the entire surface of the plantation. The gathering of the crop, however, generally commences about the first week in June, and as there is one Caper for every leaf the harvest continues until September or even October. The buds are picked by women, who work upon the same bushes every five or six days, and every effort is made to gather small Capers, as the smaller sizes are the best and bring the highest prices. The pickers are paid about 25 centimes per kilogram, or about 1d. per lb., and in the height of the season a competent woman can gather about 44lb. per day.

After the Capers have been picked they are placed in trays under a shed, so as to evaporate a portion of the water they contain. After this they are placed in barrels of white vinegar for preservation, the strength of the vinegar so used being about 8° Beaumé. Occasionally the preserving vinegar is flavoured, according to individual taste and experience and the demands of prospective market, with sprigs of Tarragon, Elder flowers, Cloves, and Pepper. During the winter the Capers so preserved are classified by being passed through sieves of different sizes. Seven classifications or sizes are recognised, and are termed "nonpareille" (the smallest size), "surfine," "capucine," "capote," "fine," "mi-fine," and "commune" (the largest size). Having been thus separated and graded, the Capers are replaced in barrels filled with vinegar and kept till sold. When the Capers are prepared for shipment they are usually washed in a vinegar of the strength of 12° Beaumé, which renders them quite firm, and they are then placed in barrels without vinegar, and can stand long journeys. The first quality of Capers are known in France as "Câpres de Toulon," and are presumed to have been grown in that district; the second quality are the "Câpres de Marseille," and the third are the "Câpres de Majorque," and each of these have some or all of the various grades we have already noted. The "Câpres de Marseille," for instance, have the following grades: nonpareille, superfine, fine, demi-fine, and ordinaire. The "Câpres de l'Espagne," which are usually large, are another recognised quality, and find a place somewhere in line with the three commercial species already named. The commercial varieties that are the least valued of all are those termed "Câpres de Lyon" and the "Câpres de Tunis," known also as "de Capènes."

The fruits of the Caper, which are as large as Italian Olives, are often preserved in vinegar, and are commercially known in France as "cornichons de câpriers." The trade in Capers is carried on principally in Marseilles, Toulon, and Grasse, and it is generally in the hands of merchants who also prepare and sell pickled Olives, sardines, anchovies, and other products which figure on French tables as "hors d'œuvre." In the North of France they preserve and sell, under the name of "Câpres de genêt," the young buds of the *Nartium scoparium*. It is stated that they are also preserved in Germany, and sold in considerable quantities in the eastern departments of France and in Holland, these "Capers" being considered a very *recherché* condiment.

R. HEDGER WALLACE.

46, Lammas Park Road, Ealing, W.

## BOOKS.

**Flora and Sylva, Vol. I.**\*—The first volume of the monthly magazine *Flora and Sylva* forms a beautiful and interesting book, and we look forward to a long series of a publication that it is a delight to possess. Mr. Robinson in the preface tells us that trees will always form one of the great features of the magazine, and we heartily agree with him in regarding the study and planting of the finer trees and shrubs as somewhat overshadowed by the greater devotion given to flowers and plants. "When we think of the beauty, use, and long life of trees, and the happy

\* *Flora and Sylva*. Vol. I. Edited by W. Robinson, and published at 17, Farnival Street, London, E.C. Price £1 1s.

results a man who plants may get in his own lifetime, there can be but one view as to the importance of the subject, and hence the place given them in this work. In the series of articles on the 'Greater Trees of the Northern Forest' it is proposed to include all the nobler trees." *Flora and Sylva* was begun in April of last year, and opened with an article on "Hardy Bamboos in England," by Lord Redesdale, and a review of the Magnolias and Calochorti, with a coloured plate of *Magnolia rustica* fl. rubra and *Calochortus clavatus* and *C. nitidus*. The coloured illustrations are one of the features of the work, two being given with each number, and they are from drawings made by Mr. H. G. Moon. The engravings and plates alone are worth the price of the magazine, and paper and printing are excellent.

The following plants are represented by a coloured plate in the first volume, the two just referred to, and *Geranium grandiflorum*, single Camellias, *Anchusa italica* var., *Colchicum giganteum*, *C. Sibthorpii*, *C. Bivonæ superbum*, *Aconitum Fisheri*, *Browallia speciosa major*, *Cherokee Rose (Rosa levigata)*, *Clematis Mme. Edouard Andre*, *Cyclamen libanoticum*, *Fritillaria askhabadensis*, *Hidalgoa Wercklei*, *Inula royleana*, *Lilium Grayi*, *Mertensia primuloides*, *Pæonia lutea*, and *Anemone cernua*. The wood engravings are very beautiful, especially of the Swiss Pine at home, page 101; the Scotch Fir (*Pinus sylvestris*), page 163; and Rose Bessie Brown, page 307. We have reviewed several of the parts already, but that for December has not yet received attention. In it are the coloured plates of the Cherokee Rose and *Ioula Roylei*, and the charming engraving of the Bessie Brown Rose to accompany an interesting article on

#### THE GREATER ROSES,

from which we take the following extract:—"This is an important subject for all who think of a real flower garden, and seek to avoid the ugliness of the pitiful substitutes for it both in France and England. The stereotyped gardens are even worse abroad than at home, since the French and Germans have taken mosaic culture from the Italians, and are riding it to death. I have lately been through one of the most beautiful parts of France—the valleys of the Loire and Cher, where all things in Nature are beautiful, from clear sky to river bank, the one human blot on the whole being the dabs of mosaic culture in spots that ought to be the most sacred—before a group of fine Cedars, the far side of a wide lawn, or against a beautiful old chateau. No such things ought ever to be seen in the foreground of a beautiful house, and to avoid these horrors we have (among other things) to think first of the *great* Roses. It is a question which is obscured by the stupid division of Roses into many classes, by giving an exaggerated value to some, and by the still prevailing error of growing mainly the summer-blooming kinds. In catalogues also we see Roses of poor quality, like *Homer*, described in glowing terms year after year, and not enough care is taken to exclude Roses which do not open well in parts of our country, like *Francisca Kruger*. Raisers, too, are not careful enough to exclude Roses of poor colour and effect for the open air, in which distant effect has to be reckoned with; and so for its colour I exclude *Marquise de Salisbury*. Also, with perhaps less reason, Roses with long and absurd rignaroles of names, and kinds like *Niphotos* and *Comtesse de Frigneuse*, which are not good for open air culture. There are also a certain number that are apt to break into many heads, like *Comtesse Riza du Parc*, which may be pretty in their first season, but gradually become less so. I was nearly excluding *Maman Cochet* for this habit and for its general want of effect throughout the year; famous as it is I should not at all place it near what I should call a *great* Rose. . . ." Mr. Robinson condemns "poor Roses such as *Crimson Rambler*, which give their few weeks of colour and then subside for the season. Such Roses may be of some value on outhouses, and among trees and shrubs here and there, and to give a pretty effect for a time, but they are not worthy of mention beside such sorts as are beautiful the whole summer and autumn. There is, unhappily, a

greater cause of exclusion than all these, and that is the effect of grafting all the fine Tea Roses on the Briar." In writing of the beautiful *Yonne Gravier* he mentions that, even when obtained from the best source, it is very apt to die when on the Briar. "A few suckers that I got on their natural roots do much better. In my trials, embracing thousands of Tea Roses, a great many constantly die back. They flower well the first year and then perish slowly, flowerless ever after. So I am haunted always by the fear that we have lost many of our finest Tea Roses in this way. I do not divide great Roses into classes, because there is no need for it. It is the modern mania for making classes when no real distinction exists, which leads our societies to classify Roses into garden and exhibition kinds, as if Marie Van Houtte and Anna Olivier, among the best of open air Roses, were not good enough to take their places in any show, even with their beautiful foliage cut off and set in ranks like Cabbages in a market stand. Dividing one group into hybrids and another into non-hybrids is not one whit more rational, for all are hybrids."

We should advise keen Rose growers to get this part with the list of the greater Roses. The article upon the "Greater Trees of the Northern Forest" is illustrated with a capital wood engraving of the "Norway Spruce at Oakley Park." We heartily congratulate Mr. Robinson. *Flora and Sylva* is a periodical for all who love their gardens.

## NOTES FROM SCOTLAND.

#### MEDALS FOR COTTAGERS' GARDENS IN SCOTLAND.

FOR a number of years the improvement of cottage gardens in Scotland has been stimulated by the medals offered annually by the Highland and Agricultural Society of Scotland. These are awarded through the medium of the local horticultural societies, and there are usually more applications for medals than can be supplied by the number allotted. It is therefore the custom to grant the medals to different societies instead of continuing them every year to the same district. This year twenty districts will receive two medals each. These prizes are generally keenly competed for.

#### ROYAL CALEDONIAN HORTICULTURAL SOCIETY.

An abstract of the accounts of the Royal Caledonian Horticultural Society for the year ending November 30, 1903, has been issued by the secretary and treasurer, Mr. P. Murray-Thomson, S.S.C. It shows a gratifying improvement in the position of the society during the past year, the balances to the credit of the society amounting to £928 5s., compared with £715 17s. 7d. on November 30, 1902, a gain of £212 7s. 5d. Of these balances £557 11s. is that belonging to capital account, the remainder being on income account. A statement of the Neill Prize Fund is also published, showing £450 to the credit of capital account, and £24 10s. 3d. to that of income.

The annual meeting of the Royal Caledonian Horticultural Society was held in Dowell's Rooms, George Street, Edinburgh, on the afternoon of the 13th inst. Mr. David P. Laird (of Messrs. R. B. Laird and Sons, Limited), one of the vice-presidents, occupied the chair. The annual report, submitted by Mr. P. Murray-Thomson, S.S.C., secretary and treasurer, was satisfactory, and showed an increase in membership of 119. Reference was made to the success of the alteration in the date of the spring show, and to the forthcoming show at the same time this year. A statement was also made regarding the international exhibition promoted by the society, to be held in 1904, and gratification was expressed at the patronage of His Majesty the King having been accorded to it, and at His Majesty's gift of a valuable cup. The financial statement, already summarised above, was also satisfactory. Mr. Alexander Milne made some remarks upon the financial statement, which he did not think altogether satisfactory, as the surplus was, in his opinion, gained by a curtailment of the prize

money. He suggested economy in some other departments. Mr. Murray-Thomson explained that a good deal of the increase in the show expenses was caused by about £100 additional having been spent on music at the spring show for the purpose of attracting the public, and that the reason of the reduction of the prize money was that the nurserymen had foregone their prizes to help the finances of the society. Several members spoke in similar terms to the secretary, and the report was adopted, on the motion of Mr. J. W. M'Hattie, superintendent of the City Parks, seconded by Mr. W. Smith, Oxenford Gardens. Lord Balfour of Burleigh was reappointed president of the society. Mr. W. H. Massie (of Messrs. Dicksons and Co.) and Mr. D. Kidd, The Gardens, Carberry Tower, were appointed vice-presidents, and the vacancies on the council were filled by the appointment of Mr. James Grieve, Redbraes Nursery, and Councillor Mackenzie (of Messrs. Mackenzie and Moncur, Limited).

#### SCOTTISH HORTICULTURAL ASSOCIATION.

The annual meeting of this association was held in Dowell's Rooms, George Street, Edinburgh, on the evening of the 12th inst., Mr. J. W. M'Hattie, president of the association, in the chair. The attendance was large. No fewer than twenty life members and fifty-one ordinary members were elected, and thirty-four proposed for election at the next meeting. Mr. Peter Loney, the secretary, read his annual report, which was of an extremely satisfactory character, and which showed a gratifying record of progress in the membership. During 1903 forty life members, two honorary members, and 191 ordinary members had been added to the roll, the membership now standing at the record number of 1,295. Mr. Todd moved the adoption of the report, which was agreed to unanimously. The abstract of accounts for the year was also submitted by Mr. W. Mackinnon, the treasurer, and was of an exceedingly satisfactory character, the total income, including the balance in hand at the beginning of the year and the balance of profit on the Chrysanthemum show, having been £1,231 8s. 5d. The ordinary expenditure amounted to £102 0s. 11d.; £25 2s. had been given to charities, and the balance to the credit of the association was £1,104 5s. 6d., a gain of £125 13s. 4d. Mr. A. Mackenzie, in moving the adoption of the report, made some appropriate remarks regarding the prosperity of the association and the good work it was doing in fostering horticulture. The report was adopted and the office-bearers thanked for their services. The office-bearers were also appointed, the principal appointments being: Honorary president, the Marquis of Linlithgow; president, Mr. J. W. M'Hattie; vice-presidents, Mr. A. Mackenzie and Mr. A. Slater; secretary, Mr. Peter Loney; treasurer, Mr. W. Mackinnon. The association's prospects for 1904 are exceedingly promising, and the papers to be read at the monthly meetings are likely to maintain the attendance at its high level.

## OBITUARY.

#### REV. CHARLES DAVIDSON.

By the death, a few days ago, of the Rev. Charles Davidson of Dumfriesshire, that district has lost one of its most enthusiastic amateur gardeners. Mr. Davidson was fond of horticulture in all its branches, but he took a special interest in hardy and florist's flowers, and his garden at Hightae Manse was always interesting. Mr. Davidson, who was one of the most respected of men, died suddenly, and much sympathy is felt for his widow in her bereavement.

#### HUGH FRASER.

We regret to learn of the death of Mr. Hugh Fraser, nurseryman, of Leith, which took place in Edinburgh on January 13. Mr. Fraser was in his seventy-first year, and was interred in Rosebank Cemetery on January 16.

# THE GARDEN

No. 1680.—VOL. LXV.]

[JANUARY 30, 1904.

## THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.

ON Thursday in last week the annual meeting of this institution was held at the Covent Garden Hotel, under the chairmanship of Mr. H. J. Veitch, followed by the usual supper, over which Mr. Leonard Sutton presided, supported by the majority of the committee and friends interested in this famous gardening charity. A report of the proceedings is given on page 86, but the institution, so thoroughly managed, and at small expense, demands a more general notice than an ordinary report, to which, however, we draw attention to show the substantial foundation upon which the institution is built. Year by year the committee appeal earnestly for funds to meet the distressing cases brought before their notice, and this year thirty-eight applicants must await their chance next January before their appeal for a pension can again be considered, and then, we fear, the majority have small chance of securing the necessary number of votes.

A glance at the report published shows a satisfactory state of things as far as the financial condition of the institution is concerned, but it is to the gardeners of the United Kingdom that the committee naturally look for increased support. Only 1,000 are sufficiently wise to subscribe to an institution which may be the means of imparting some comfort to them in the future, and, as Mr. Veitch pointed out at the meeting, those men who begin to subscribe when they are young are those who will reap their reward in the years to come, when the institution is appealed to for assistance from the pension or one of the other funds, which have been founded to give temporary assistance in time of distress and sickness. If the gardeners would take their share in supporting the institution its sphere of usefulness would be extended, and the committee be enabled to give relief to the sad cases which at every meeting are brought before them for investigation. Charitable institutions such as this must be managed with strict prudence, and of all the charities in which we have been interested none is handled with greater economy and foresight than the Gardeners' Royal Benevolent. It is not the men alone that are considered; it is the widow too, and the pension of £16 a year to the

widow saves the recipient from what would be practically in many cases starvation. When a pensioner dies the wife is placed on the funds without election, provided that the committee consider the case deserving of this action.

We earnestly appeal to the young gardener in particular to take heed of the future and subscribe to the institution, and by so doing, through the greater number of votes given to the oldest subscriber by the committee, ensure quick election when relief is sought. And the institution is not merely centred in London. It has now several auxiliaries, which are accomplishing, and will do so more in the future, incalculable service in broadening the basis of the institution, and in this good work Mr. Veitch has ever taken the keenest interest. The Reading auxiliary has been instrumental not only in raising a substantial sum but in making the institution known in the surrounding country, and we know that the Liverpool branch is extending, as well as those in Bristol and Bath, Worcester, Devon and Exeter, and Wolverhampton. We should like to see branches started in Manchester and all the great towns, with enthusiastic secretaries to make the claims of the institution known far and wide.

Although in the report we read of the "continued success and increased usefulness of the charity," we are not unmindful that comparatively few of the applicants had any chance whatever of election this year. As the report says: "Their cases are most sad, and the committee sincerely wish it was in their power at once to grant them, or at least some of them, that permanent assistance for which they plead and of which they are so much in need. The committee, therefore, whilst thankfully acknowledging the help afforded them in the past, very earnestly appeal to all friends and well wishers for their co-operation in obtaining additional support for this national horticultural charity, so as to warrant an enlargement of its beneficent objects on behalf of those, in their days of need, who in their time have done their best to minister to the pleasure and necessities of others."

The committee are determined that no effort shall be spared in developing to the utmost this famous charity. A history of the institution will soon be published, and leaflets will appear in as many publications as possible, including trade catalogues, where permission is granted. But those who govern must be supported. It is to the gardener as

well as to the many friends of the institution who open wide their purse-strings to relieve sickness and distress that an earnest appeal is made, and we hope not without substantial success.

Then there are the two special funds which have been the means of giving immediate help to the applicants. The report says:

"The special funds, viz., the Victorian Era Fund and the Good Samaritan Fund, are, happily, still a source of incalculable benefit and help. From the former fund, £135 10s. has been distributed during the year to the unsuccessful candidates who had previously been subscribers, in proportionate amounts, according to the number of years they had subscribed; and from the latter fund, which is for the assistance of subscribing and also non-subscribing applicants, no less than £81 has been awarded in temporary assistance in cases of urgent need, many of which were of a particularly distressing and pathetic character. The grateful letters which have been received from the recipients of aid from these special funds, as well as from the general fund, show how much the help was needed, and how greatly it was appreciated."

Few have done greater service to the institution than Mr. H. J. Veitch, who will take the chair at the yearly dinner in the Hotel Metropole, the date being June 28. A chance is offered of making this a great gardeners' year. The forthcoming chairman has earned the sympathy of all interested in horticultural charities, and he deserves a record subscription list as one means of showing the esteem in which he is held by horticulturists throughout the land.

## ROYAL HORTICULTURAL SOCIETY.

THIS famous society celebrates its centenary this year, and the annual report has therefore a special interest. The following are a few extracts, and it will be seen that the council intend that the hundredth anniversary of the Society's foundation shall not pass by without special celebrations of so interesting an event. We doubt the wisdom of raising the annual subscription to two guineas a year, and the council may expect strong protests from country members, to whom the ordinary events of the Society are of little interest.

### A PROPOSED DINNER.

The year 1903 will long be noteworthy in the annals of the society. Not only does it complete (1) one hundred years of the society's

existence, but it has also seen (2) the commencement of the new hall and offices, (3) the inauguration of a new garden, and (4) the largest numerical addition to the list of Fellows that has ever taken place in the society's history. To celebrate the one hundredth year of the society, it has been decided to hold a centennial dinner at the Hotel Metropole on Thursday, March 3, the nearest convenient date to the actual completion of the centenary, which will take place on Sunday, March 6 next, the society having been founded on March 7, 1804, by Mr. Charles Greville, Sir Joseph Banks, Mr. Richard Anthony Salisbury, Mr. W. T. Aiton, Mr. W. Forsyth, Mr. James Dickson, and Mr. John Wedgwood. The Right Hon. the Earl of Onslow, Minister for Agriculture and Horticulture, will preside at the dinner, and the council hope that a very large number of the Fellows will join in the celebration. The dinner tickets, which the size of the room unfortunately necessitates being confined to gentlemen, will be 21s.

#### CELEBRATION OF THE CENTENARY.

While the centennial dinner is the social commemoration of a striking anniversary, the council have had under consideration, for not less than five years, in what way the centenary could be most worthily celebrated.

Two projects speedily came into prominence—(1) a new hall and offices for the society's exhibitions and shows and for the accommodation of the library and of the office staff; and (2) a new garden less exposed to London smoke, fog, drainage, and crowding than Chiswick has of late years become.

These projects having been very deliberately considered, the Fellows finally decided in general meeting assembled to adopt the proposal of a hall.

Meanwhile, several influential Fellows, who preferred the establishment of a new garden as the celebration of the society's centenary, had been urging their views in certain quarters, and on August 4, 1903, Sir Thomas Hanbury, K.C.V.O., having asked for an interview with the council, offered to purchase the late Mr. G. F. Wilson's famous garden and estate at Wisley, comprising sixty acres of land, and to place it in trust for the use of the society as a garden as long as the society desired to retain it.

#### PROPOSED INCREASED SUBSCRIPTION.

After very grave consideration the council have decided to advise that the minimum rate of Fellowship should in future be raised to £2 2s. except in the case of *bona fide* gardeners, persons living abroad, and journalists writing for provincial or foreign newspapers. The existing £1 1s. Fellows will, of course, be under no compulsion to change the rate of their subscription, though it is hoped that not a few will voluntarily do so. The council have therefore directed a new bye-law to be drawn up and submitted to the meeting for approval, the effect of which will be, if carried, to make the lowest subscription for Fellows in future £2 2s. except in the cases mentioned.

It may be as well to point out the return value which a Fellow will receive for his £2 2s. subscription: Three tickets admitting to the Temple Show, first day, £1 2s. 6d.; second day, 7s. 6d.; third day, 3s.; the Holland House Show, first day, £1 2s. 6d.; second day, 7s. 6d.; seventeen exhibitions at Drill Hall or Vincent Square, at 2s. 6d., £6 7s. 6d.; eight exhibitions at Drill Hall or Vincent Square at 1s., £1 4s.; the society's journal, £1 10s.; total, £12 4s. 6d.

To this must be added, free advice on all ordinary garden subjects; investigation of

plant diseases, &c., by the scientific committee; a share of plants at the annual distribution; facilities for chemical advice, &c.

## CIDER MAKING IN DEVON.

"Oh, bid the cider flow,  
In ploughing and in sowing,  
The healthiest drink I know  
In reaping and in mowing."

AUTUMN in the country is full of delights—Blackberrying in the lanes, or glorious days spent among the woods and on the covert side, where the pheasant rises over the tree tops with a whirring sound, and the muffled "tap, tap" of the beaters is heard from the thicket. The hedges are gay with Bryony and scarlet Hips and Haws, trails of mellowing Briars, late Honeysuckle, and Traveller's Joy. But it is of a quaint old farm that I would write, where cider has been made from time immemorial.

The Devon farms are very picturesque; long and low, with thatched roofs, and walls of yellow "cob" mellowed with age. There is often fine Oak panelling in these farms, many of which have been manor houses of some importance. The big kitchen looks very comfortable with its huge open fireplace and snug ingle nook, the farmer's dinner stewing in a large iron pot swung from the ceiling by a long chain. There is a delightful smell from the wood fire, and the Marrow or Gooseberry jam that is simmering in a large pan, home-cured hams hang from the stout oak beams—a provision for the coming winter. September gales have blown down a good many trees in the Apple orchard that slopes down the steep hillside, but although this has been anything but a good year for Apples there seems to be a fine crop still hanging on the trees, or lying in rosy heaps beneath, waiting to be touched by the first frost before they are taken into the cider barn. October and November are the months for cider making, and fine weather is always chosen for the Apples to be gathered. The best kinds of Apples in these parts, at least, are the "Sweet Alford" and "Suelling." It is easy to find the way to the barn, for the faint, sweet smell of Apples penetrates far and wide, and there is the sound of swiftly rushing water, which, from a stream that flows from the wooded hills above, turns the great water wheel that works the primitive machinery of the cider press. The high priest of the cider making looks rather like an Apple himself with his rosy, wrinkled face. He is very proud of his cider, and takes great pains to explain the making of it, and its great superiority over the cider of manufactories, which is mixed with all sorts of ingredients instead of being as this is—just the juice of Apples, not even water being added. It is somewhat difficult to understand his explanation of the cider process, as he speaks in the broadest Devon. When the Apples have remained on the ground for a week or so they are taken to a loft above the barn or piled on the floor, where small iron rollers crush them into a fine pulp called "pomage," which then falls below into a huge barrel like a miniature Tun of Heidelberg. When the tub is filled the Apple pulp is placed between thick layers of straw under a great stone weight, which is set in motion, and the cider drips slowly through the straw into the vat, and is received into a great granite trough or "kieve." The lever is worked by hand, and as the stone weighs several tons it is a somewhat lengthy business. The cider looks uninviting enough as it runs into the kieves, a dark brown liquid, but it is carefully strained into casks and allowed to stand for a few days, so that all impurities rise to the top and can be skimmed

off. Then comes the process of "matching," when once more the cider is strained into fresh casks, and brimstone added, which prevents too much fermentation. After standing a month or so the cider is ready to drink, and very good it is. After the first pressing is done, the pulp or "mock" is pared down and added to. This is called "shearing the mock." This is done three times, after which the "mock" is thrown away or given to the pigs.

It is a picturesque old barn where the cider making is carried on. In one corner stand two large mill stones of days gone by, the farmer's gig, in which he goes to market, and piles of hay; fowls wander in and out, and pigs, straying from the farmyard, look inquisitively round the open door at us. A tiny calf, hobbled by a leg to a post, bleats for its mother, who has gone off to the pasture, one of a herd of Devon cows, red as the Devon hills.

There are several superstitions about cider making. On Christmas Day in old times the farmer used to go at night into the orchards and fire a blank charge at the trees—a sure way, he believed, to bring a good crop during the ensuing year. There is another legend of an Exeter brewer who, being jealous of the popularity of cider, sold his soul to the devil on condition, that every year, three nights' frost in May called "St. Frankin's days," should spoil the Apple blossom. This compact with the Evil One would not possess so much significance nowadays, when summer frosts are such usual occurrences. While writing this short description of a visit to the cider farm it is tempting to quote a verse from a quaint old song mentioned in a book of west country lore, to which I am also indebted for the two superstitions regarding cider makers. Speaking of the famous Devon orchards, the old poet says:

"An orchard fair to please,  
And pleasure for your mind, sir,  
You'd have—then plant of trees  
The goodliest you can find, sir.  
In bark they must be clean,  
And finely grown in root, sir,  
Well trimmed in head, I ween,  
And sturdy in the shoot, sir."

"Oh, the jovial days when the Apple trees do hear,  
We'll drink and be merry all the gladsome year."

DOROTHY HAMILTON DEAN.

## THE EDITOR'S TABLE.

WE invite our readers to send us anything of special beauty and interest for our table, as by this means many rare and interesting plants become more widely known. We hope, too, that a short cultural note will accompany the flower so as to make a notice of it more instructive to those who may wish to grow it. We welcome anything from the garden, whether fruit, tree, shrub, Orchid, or hardy flower, and they should be addressed to The Editor, 5, Southampton Street, Strand, London.

#### WINTER-FLOWERING SHRUBS FROM NEWRY.

Mr. T. Smith, Daisy Hill Nursery, Newry, sends three winter-flowering shrubs, one the little Rhododendron dahuricum, the deep purple-flowered Daphne Dauphina, and the crimson Grevillea rosmarinifolia.

#### LUCULIA GRATISSIMA.

"H." sends a boxful of the beautiful Luculia gratissima which were cut from several plants in a cool greenhouse. The fragrance of the flowers filled the Editorial room, and the soft pink colouring is very beautiful too. It is a winter flower of the greatest beauty, but the plant is not easily grown. We hope our correspondent will tell us under what conditions the plants are grown to achieve such excellent results.

FLOWERS FROM NAPLES.

Three interesting flowers come to us from Mr. William Müller, Naples. One is the purple-flowered

PRIMULA MEGASEEFOLIA,

which is now becoming well known, and a great favourite for its beautiful colouring and freedom; the centre is deep yellow. It is a Primula for all good rock gardens and for the alpine house, and is now in bloom in the famous garden of Mr. Ch. Sprenger.

CORONILLA GLAUCA AND COTYLEDON MACRANTHA.

The Coronilla with its yellow flowers is one of the freest and most beautiful of plants in bloom now, and the scarlet bell-shaped flowers of the Cotyledon give a bright note of colour to the plant house at this season.

MESSRS. WILLIAM BULL'S PRIMULAS.

We recently had an opportunity of seeing some of the Primulas grown by Messrs. William Bull and Sons, King's Road, Chelsea, S.W., and among them are many good varieties. One of the finest of all is Snowdon; the flowers are very large, as much as 2½ inches across, beautifully fringed, the petals overlapping each other so as to impart great depth to the blooms. A new Primula of great merit is Fairy Queen, one of the giant section. The flowers are large and of good substance, and the colour is a beautiful pink. Primula Duke of York, also a new variety, bears very handsome rich crimson flowers. The plant is of sturdy and robust habit, producing the blooms well above the foliage. Among older varieties, taking first the singles, are Comet, with rich carmine-crimson flowers, shaded magenta; Countess, delicate blush-pink; Fulgens, scarlet-carmine, with small yellow eye—a very striking Primula; Imperial Blue, with large fringed blooms of a pleasing lilac-blue shade; Mont Blanc, bearing large, densely-fringed, snow-white flowers that are always admired. Pink Beauty, with beautiful blush-pink flowers, and Sunshine, brilliant magenta-crimson, are worth special note, as also is Ruby Queen, of a ruby-red colour, tinged with purple. Among the double varieties are Blushing Beauty, a new and beautiful Primula with large blush-pink double flowers; alba fl.-pl., rosea fl.-pl., and rubra fl.-pl., all of which are well worth growing; fulgens fl.-pl. is undoubtedly one of the best and finest coloured double Primulas. Messrs. Bull and Sons' Fern-leaved Primulas and their strain of P. sinensis fimbriata alba and rubra are also deserving of mention.

THE WILD PINKS.

(Continued from page 52.)

D. NITIDUS.—A pretty plant, with leaves somewhat similar to those of D. alpinus, but having generally more acute points. The stems are two to three-flowered, springing from tufts of grass-like leaves. A native of the calcareous Alps in Hungary, it is found in sub-alpine pastures, producing its rose-coloured flowers with dentate petals in August and September. Suffering a good deal from damp, this plant requires a dry position, wedged between stones.

D. NŒANUS.—A very distinct species, with tufts of fine rigid foliage from Rumelia and Servia. Very free-flowering, the slender stems are 6 inches to 9 inches high, branching at the top into two to three divisions, each terminating with a solitary small white flower, the petals of which are incised. A free grower, it will succeed in any sunny position in gritty loam. A summer-flowering species.

D. PETREUS (the Rock Pink) was introduced from Eastern Europe in 1804. Somewhat like the above species, but with broader and less rigid foliage, the rose-coloured, beardless flowers are produced on slender stems, branching at the top into three to four in summer.

D. PINIFOLIUS.—Tufted and wooded at the base, with freely branching stems, clothed with numerous long, very fine leaves. The flowering stems are slender, 1 foot to 1½ feet high, in the wild specimens only producing one to two pink flowers on each stem; but in cultivation three to four are borne on each. This curious tufted alpine grows in stony places on Greek mountains, flowering in June.

D. PUBESCENS.—This biennial species is a native of Greece. The whole plant is covered with a fine pubescence, and the flowering stems are much branched, each branch terminating in a single flower, the whole at a little distance having the appearance of a cluster. Flowers red in summer.

D. PUNGENS.—A Spanish species, growing on rocks and mountain pastures in Asturia. A dwarf, tufted plant, with subulate leaves and solitary or few flowered slender stems. The flowers are pink with entire petals.

D. SICULAS.—A tufted plant, with long grassy leaves, and tall, branching stems 1 foot to 1½ feet high, with solitary red flowers, having incised petals. A native of the Mediterranean region.

D. STRICTUS.—A small white flowered species, this plant quickly forms large tufts of glaucous foliage, and apart from its flowers is useful for covering the rougher parts of the rock garden. It is found growing on rocks in Eastern Europe. D. s. var bebius has broader leaves and larger flowers.

D. SUBACAULIS.—A very dwarf tufted plant, with solitary flowers, on short stems from the Dauphiny.

D. SYLVESTRIS (the Wood Pink) is found in great abundance in rocky and stony places on Mount Jura and the neighbouring Alps. It was once credited by some authorities as being the origin of the Carnation, but has no fragrance. One of the prettiest and easily grown of the Rock Pinks, it forms a tuft of slender, grassy leaves, bearing a profusion of pink flowers on rather weak stems. The plant has a creeping root or underground stem, and is best planted in loose, stony soil on a sunny ledge, where the roots can penetrate and find moisture below. Introduced in 1814.

D. TENER.—From the Piedmont, with slender one-flowered stems, and beardless pink flowers with lacinate petals in summer.

D. VISCIDUS.—From the mountains of Greece and Macedonia, with loose heads of flowers resembling those of D. deltoides, but larger and deeper in colour.

D. ZONATUS.—A native of the arid mountains in various parts of Asia Minor, it is somewhat like the Wood Pink, with rose-coloured bearded flowers, having a purple zone.

D. ARENARIUS.—This species is remarkable for its deeply-fringed petals, which are cut to below the middle. They are also each marked with a faint green spot, covered with short, dark purple hairs. The plant is slightly woody at the base, dividing into many branches, terminated with tufts of linear leaves, from the centre of which springs a stem seldom bearing more than one or two white flowers. Very hardy, and growing in almost any position; it is a sand-loving plant, being found on the sandy shores of the Baltic, whence it was introduced in 1804. Flowering in summer, it is a good plant for covering old walls, where it will root into the crevices and hang down over the face.

D. GALLICUS.—A plant of loose, straggling habit, with beardless pink flowers and deeply incised petals produced in May. A native of South-Western Europe; it is found near Biarritz growing in sand-hills under the Pines.

(To be continued.)

INTERESTING PLANTS IN FLOWER.

Temperate House.

ACACIA BAILEYANA, A. dealbata, Barosma lanceolata, Brachysema Drummondii, Clematis grewiflora, Daphne Dauphinoi, D. odora, Hardenbergia monophylla alba, Illicium floribundum, and Rubus rosæfolius.

Palm House.

Brownea Crawfordii and B. grandiceps.

Range.

Anthericum triflorum, Brodiaea sellowiana, Lachenalia pendula, Thysacanthus rutilaas, Tillandsia bulbosa, and Scilla peruviana.

Orchid Houses.

Bulbophyllum dayanum, Cochlioda sanguinea, Cologyne sulphurea, Cynorchis lowiana, C. villosa, Cypripedium callosum, C. deedmannianum, C. lathamianum, C. Lowii, C. nitens, C. rothschildianum, C. virens, and others, Dendrobium atro-violaceum, D. burfordiense, D. luteolum, Epidendrum Armstrongii, E. ciliare, E. ciliare var. latifolium, E. Eodresii, E. kewense, E. Wallisii, Eria bicolor, Gomezia Barkeri, Lælia anceps, Lycaste lasioglissa, Masdevallia ignea, M. melanopus, M. polysticta, Odontoglossum maculatum var. donnianum, O. pardinum, Oncidium suave, Phalænopsis schilleriana, Platyclinis arachnites, Saccobolium violaceum, Selenipedium cardinale, S. klotzschianum, Sophronitis violacea, Stelis tristyla, Tainia penangiana, and Trichopilia sanguinolenta.

Succulent House.

Aloe chloroleuca, Cotyledon fulgens, and Rhipsalis crispata var. purpurea.

Greenhouse.

Cestrum elegans, Cheiranthus kewensis, Coleus thyrsoides, Eriostemon myoporoides, Eupatorium petiolare, E. vernale, Jacobinia coccinea, Kennedyia prostrata, Primula sinensis vars., Rhododendron præcox, Senecio grandifolius, S. Feltham Beauty, Sparmannia africana, and Hyacinths, Lily of the Valley, Tulips, and other forced things.

Alpine House.

Bulbocodium vernum, Colchicum crociflorum, C. hydrophilum, C. libanoticum, C. luteum, Corydalis ledebouriana, Crocus acyrensis, C. Imperati, C. reticulatus, C. Sieberi, Cyclamen Atkinsii, C. ibericum, Galanthus byzantinus, G. nivalis, Iris reticulata var. histrioides, I. Vartani, Nocca stylosa, and Scilla sibirica.

HAMAMELIS MOLLIS.

In the interesting note on Hamamelis which appeared in THE GARDEN of the 23rd inst. no mention was made of Hamamelis mollis, which bids fair to be as good, if not better, than H. arborea, which is the most ornamental of the older species. H. mollis is a strong-growing shrub, introduced from China by Messrs. Veitch of Chelsea in 1898. As yet small plants only are to be found in this country; one 4 feet high is recorded in Messrs. Veitch's nursery at Coombe Wood, but in China it is said to grow 30 feet high. It differs from all other species of Hamamelis by having large, broadly-ovate leaves, thickly covered with a felty mass of stellate hairs. The flowers are bright yellow, and larger than those of H. arborea, and instead of the petals being twisted, as in that species, they are straight with hooked ends. It also blossoms earlier than H. arborea, being quite a fortnight in advance at Kew this year. During the sharp frosts experienced last May the Kew plants were badly damaged, all the young shoots being killed; but they broke again from dormant buds on the old wood, and made strong branches from 9 inches to 18 inches long before the end of summer. Anyone who grows Hamamelis should obtain this plant. All the Hamamelis are interesting, and H. mollis is not the least important. It will probably soon be grown in all good gardens.

Kew.

W. DALLIMORE.

## NOTES OF THE WEEK.

## FORTHCOMING EVENTS.

February 2.—National Amateur Gardeners' Association Meeting.

February 6.—Société Française d'Horticulture Meeting.

February 8.—United Horticultural Benefit and Provident Society Committee Meeting.

February 9.—Royal Horticultural Society's Drill Hall Meeting; Horticultural Club Annual Meeting, 5 p.m., Annual Dinner, 6 p.m. Sir John Llewelyn, Bart., chairman of the club, will preside.

February 10.—East Anglian Horticultural Club Meeting.

February 12.—Royal Gardeners' Orphan Fund Annual General Meeting.

February 23.—Royal Horticultural Society's Drill Hall Meeting, 12 noon.

**New superintendent of the Leicester parks.**—We understand that Mr. W. Burton, who assisted Mr. John Burns in the management of the Leicester parks, has been appointed to succeed him. As was announced last week Mr. Burns relinquishes charge of these parks at the end of January.

**Government enquiry on fruit culture.**—The departmental committee of the Board of Agriculture and Fisheries appointed to enquire into and report upon the present position of fruit culture in Great Britain, and to consider whether any further measures might with advantage be taken for its promotion and encouragement, held their preliminary meeting on Friday, the 22nd inst. The method of procedure at future meetings, and the nature of the evidence to be taken, was discussed.

**Scottish Arboricultural Society's Jubilee.**—The council of the Royal Horticultural Society have received a courteous invitation to send a representative of the society to the Jubilee of the Royal Scottish Arboricultural Society, which takes place on February 16, and they consider themselves fortunate in having obtained the consent of Mr. A. D. Webster, F.R.H.S., to represent them on this occasion.

**The Royal Horticultural Society and its subscription.**—I have read with no little surprise the following paragraph in the splendid report of the Royal Horticultural Society, recently issued: "The exceedingly rapid increase in the number of Fellows (1,412 having been added during the last twelve months), gratifying as it is as a proof of the appreciation of the society's work by the lovers of gardens, appears nevertheless to the council to contain an element of danger, inasmuch as it is becoming more and more difficult at times for Fellows to see the flowers, &c., without serious discomfort from crushing and crowding. After very grave consideration the council have decided to advise that the minimum rate of Fellowship should in future be raised to £2 2s., except in the case of *bona fide* gardeners, persons living abroad, and journalists writing for provincial or foreign newspapers. The existing £1 ls. Fellows will, of course, be under no compulsion to change the rate of their subscription, though it is hoped that not a few will voluntarily do so. The council have therefore directed a new bye-law to be drawn up and submitted to the meeting for approval, the effect of which will be, if carried, to make the lowest subscription for Fellows in future £2 2s., except in the cases mentioned." Will you allow me, as a country Fellow, to protest against this unwise decision, which, if approved, is bound to have a hampering influence upon the society in the future? Surely the policy of the council should be to endeavour to still further increase the membership and widen the scope of the society rather than to attempt to curtail it. At this juncture it is interesting to compare the first paragraph in the report for 1902, which reads as follows: "It is gratifying to the council to record that in this, the ninety-ninth year of the society's existence, a larger number of new Fellows joined the society than in any year since its first establishment in 1804. The exact number of new Fellows elected in the past year has been 1,140, which, if contrasted with the

1,108 who formed the whole number of the Fellows when the society left South Kensington in January, 1888, indicates the development which is continuously taking place in the society. *The council hope that everyone who has the society's welfare at heart will continue to endeavour to promote it by enrolling new Fellows.* The italics are mine. Thus in almost less than twelve months we find the council expressing two irreconcilable opinions, and the only explanation vouchsafed is that "it is becoming more and more difficult at times for Fellows to see the flowers without serious discomfort from crushing and crowding." This appears to me to be only a paltry excuse, as, except for the Temple show and an occasional Drill Hall meeting, I cannot say that I have ever experienced any "serious discomfort"—certainly not enough to warrant the drastic and restrictive proposal put forward by the council. Sir Trevor Lawrence, Bart., in his short historical sketch of the society, says: "*In reducing the minimum subscription to £1 ls. in 1888, the society was actuated by a desire to enrol amongst its Fellows as large a proportion as possible of the vast number of their fellow subjects who are interested in gardens.*" Now, sir, I do not intend to call in question the great value which Fellows receive in return for their subscriptions. Great credit is due to the society for giving so much and asking so little. This policy has found its reward in the rich harvest of £1 ls. Fellows, who are, after all, the backbone of the society. There are hundreds of Fellows throughout the country who are unable to attend any of the shows and meetings, but have simply joined in order to secure the invaluable Journal. More are still joining simply for this very purpose. Why not leave well alone? We are all justly proud of our society, and for my own part I only echo Sir Trevor Lawrence's own words when I say that I hope to see the numerical strength of the society still further increase until that "vast number" of people "who are interested in gardens" are enrolled as members. Another point occurs to me. Why do not the council propose an entrance fee, say of £1 ls., as is done in so many other societies? This would, I feel sure, meet with the approval of most of us. In the meantime I hope those who are opposed to this new move on the part of the council will attend the general meeting on February 9 and vote against this attempt to restrict the membership of the society for the benefit of the few instead of the many.—ARTHUR R. GOODWIN, *The Elms, Kidderminster.*

**Trees for George Street, Edinburgh.**—Some difficulties have arisen in connexion with the tree planting in George Street, Edinburgh, and it is doubtful if the proposals will now be carried out. It has been found that the soil is of such a character that a good deal of feeding would be required if the trees are to be kept in a healthy condition for any length of time. A number of the business men object to the planting, and although the sub-committee to whom the question was remitted did not come to a decision at their recent meeting on account of the absence of the proposer of the scheme, the feeling seemed adverse to the scheme. From an artistic point of view, George Street is one of the best in Edinburgh for tree planting, but, of course, other considerations have frequently to prevail in such matters.

**The Kidderminster Horticultural Society.**—This is one of the most progressive horticultural societies in England, and it is a pleasure to record that a profit of £37 was made last year. Mr. Goodwin, chairman of the lecture committee and one of our best-known contributors, sends the list of fixtures for this year. We notice that several very interesting lectures will be given. Mr. Goodwin lectures on "The Daffodil" on April 16, and Mr. C. E. Pearson of Nottingham will give his charming discourse, illustrated with lantern slides, entitled "Birds and Flowers in Russian-Lapland." This, it may be remembered, was given last year at the Horticultural Club. Other lectures include Mr. T. W. Sanders, F.L.S., on "A Chat about Gardens and Gardening," Mr. F. W. E. Shirvell, F.L.S., Mr. H. Bulmer, Mr. W. H. Wilson (Stonrivel), Mr. Benjamin Howard, and Mr. E. H. Mashrey. The president is Sir Frederick

Godson, M.P., and the secretary Mr. C. Sadler, 59, Sutton Road, Kidderminster. The Narcissus show takes place on April 16 at the Corn Exchange, and three other shows will be held, viz., on Saturday, July 9, in the grounds of Cairndhu (by kind permission of Mr. Peter Adam); Thursday, August 11, and September 8, both at headquarters.

**Flower show for Inverurie, N.B.**—A largely-attended public meeting was held recently in the Public Hall, Inverurie, N.B., to consider the desirability of establishing a flower show in the burgh. Bailie Moir occupied the chair. The feeling of the meeting was unanimously in favour of the object for which it was called, and it was agreed to take the necessary steps to establish a horticultural society. It is intended that the show, with which will be connected an industrial exhibition, should be held in August. Mr. James Eddie, F.R.H.S., was appointed secretary, and the other preliminary steps to carry out the project taken. An impetus has been given to the movement by the removal of the locomotive works of the Great North of Scotland Railway Company to the burgh. This has largely increased the population, and from the convenient position of Inverurie it is expected that the show will be well supported in the district.—S.

**Dust in Glasgow.**—In the course of an admirable lecture on "The Atmosphere of Glasgow," given recently by Mr. P. Fyfe, the chief sanitary inspector of the city, some remarkable figures were given, which will enable readers to realise the difficulties to be encountered by those who seek to cultivate plants in and near the great city on the Clyde. By means of a number of dust gages a test was made of the amount of solid matter deposited in Glasgow. The gauge in the Alexandra Park gave the highest amount, and registered 228 grains of solid matter to the square foot in seventy days. Of this 204 grains were mineral or incombustible matter, 67 grains organic matter, and 17 grains of oily matter. It is not surprising that the proportion was so high, as the Blochairn Ironworks are close by, and these have forty-five chimneys, which are estimated to give 20,000,000 cubic feet of black smoke every day of twenty-four hours, producing 3 tons 10cwt. of solid matter per day, or 1,277 tons per annum. The gauge at the Queen's Park showed the least solid matter, it being at the rate of 5.6cwt. per annum per acre. Taking Queen's Park as an example, that would give over the area of Glasgow 3,584 tons per annum. The Alexandra Park rate would mean 53,428 tons per annum, or 146 tons per day. The average over all gave at the rate of 23,321 tons per acre per annum, or 1,166'08 tons per square mile in the same period. It is surprising with all this how plants can be grown in even the worst places. Most careful cultivation is required.

**Accommodation for Scottish Societies in Edinburgh.**—In connexion with some proposed changes in the occupation of the buildings on The Mound, Edinburgh, presently occupied by the Royal Institution, &c., a movement has been inaugurated to have these devoted to the use of the various Scottish scientific societies which have their headquarters in Edinburgh. In furtherance of this object a deputation recently waited upon Mr. Graham Murray, K.C., M.P., the Secretary for Scotland, to lay the matter before him. The deputation was a most influential and thoroughly representative one. Among the societies represented were the Botanical Society of Edinburgh, the Royal Scottish Arboricultural Society, and the Field Naturalists' and Microscopical Society. The first was represented by Dr. William Craig and Dr. R. Stewart Macdougall, the second by Mr. R. C. Munro Ferguson of Raith, M.P., Mr. R. Galloway, and Colonel Wardlaw Ramsay, Mr. J. Russell representing the Field Naturalists' Society. Lord McLaren, who was one of the number from the Royal Institution, was the spokesman of the Botanical Society, and laid the claims of this and others which only required accommodation for their meetings before Mr. Graham Murray. A valuable feature of the proposal is that a scientific library should be included for the use of the members of the various societies.

**Apple Northern Spy.**—I have recently had from Canada several excellent samples of this Apple, as regards flavour, size, and appearance. A friend with nineteen years' experience in the North Island, New Zealand, said that if he planted fifty acres of Apples Northern Spy would be the only variety. Can any of your readers say how this Apple succeeds in England?—A. M., *North Lincs.*

**Extension of fruit growing in Scotland.**—The Scottish Wholesale Co-operative Society has just taken an important step in extending its operations by the purchase of the estate of Calderwood for fruit growing, cattle rearing, &c. Calderwood extends to about 1,125 acres, and the purchase price is, we believe, £37,500. The castle, a fine building, is, it is understood, likely to be converted into a convalescent home, while the vineries, Peach houses, and other glass structures are to be used for growing indoor fruits, &c., for the trade of the society. We are informed that it is the intention of the directors to enter into the cultivation of hardy fruits to a considerable extent, so that a large amount of labour will be employed in fruit cultivation, gathering, and packing. Calderwood is only a few miles from Glasgow, and is well adapted for the purposes for which it has been purchased.

**The Scottish rainfall of 1903.**—From a very interesting comparative statement of the rainfall at some of the Scottish towns, which has just been issued, it appears that the excessive rainfall has been even greater than was anticipated. A noteworthy feature is the manner in which the excess was distributed, the western and southern districts having a much larger increase than the northern and eastern. Thus Fort William had a rainfall of 108.56 inches, 47 inches more than in 1902, and 34 inches more than the average. Greenock had 87.35 inches, Paisley 69.57 inches, Glasgow 51.19 inches, and Dumfries 50.45 inches. In the north and east, Aberdeen had 37.29 inches, or rather less than 10 inches more than last year, or 6 inches above the average. Dundee came next with 35.33 inches, Edinburgh had 33.24 inches, and Nairn 29.31 inches. The difficulties of gardening with such a heavy rainfall as that of the south and west can be well understood, and much work is still greatly in arrear.

**Native Mosses at Glasgow Botanic Gardens.**—There are not many who take a real interest in the native Mosses, many of which are very beautiful; but among the few is Mr. Scott, the propagator at the Glasgow Botanic Gardens, who has a remarkably good collection, grown in pots and pans in frames. Such a collection is particularly valuable in a botanic garden, as it gives one an opportunity of learning something about the names of our native Mosses much more readily than can be obtained from books alone, and the many Nature students in the neighbourhood of Glasgow may derive considerable advantage from a study of Mr. Scott's specimens. It is gratifying that Mr. Whitton, the superintendent of the Glasgow City parks, takes an interest in these subjects himself, and gives facilities for their cultivation by members of his staff. It may be mentioned that the collection is not in the portion of the gardens open to the general public, but students of these plants would have little difficulty in seeing them.

**How Mushrooms grow.**—Writing on fungi in the current number of *Knowledge*, Mr. George Masee states that "in all fungi the portion visible to the naked eye, however varied its form or colour, represents only the reproductive portion; whereas the vegetative part is buried in the substance from which the fungus obtains its food. The popular belief that the Mushroom and other fungi grow in a single night is not correct; it is quite true that when the Mushroom has reached a certain stage of development, one or two days suffices for it to attain its full size after it appears above ground. Before this final spurt is reached, however, the baby Mushroom has been growing for some weeks, and undergone various changes of structure and development before it emerges above ground. A little thought will recall to mind the fact that Mushrooms do not

spring up within two or three days after the formation of a Mushroom bed, but several weeks elapse before the Mushrooms are ready for the table. . . . The various methods of spore dispersion as occurring in the fungi are interesting; only a few of the most pronounced can be noticed here. By far the most universal agent in effecting the distribution of spores is wind, as may be observed when a ripe Puffball is crushed under foot. Insects are also answerable for the extension of many fungus epidemics, by alternately feeding on, or visiting diseased and healthy plants, and in so doing unconsciously conveying spores from one plant to another. Perhaps the most interesting instance occurs in a group of fungi to which our Stinkhorn belongs. Most of the species are tropical; in this country we have only three representatives. In this group the reproductive portion of the fungus often assumes most fantastic forms, and is generally brilliantly coloured. Over this framework is spread at maturity a dingy green, semi-fluid mass, intensely sweet to the taste, and, from the ordinary human standpoint, intensely foetid. The exceedingly minute spores are imbedded in this substance, which is greedily devoured by various kinds of insects, mostly flies, who thus unconsciously diffuse the spores, as it has been shown that these are not injured by passing through the alimentary tract of an insect. It is interesting to note that in certain of the fungi the same advertisements in the guise of colour, sweet taste and smell, are used for the purpose of unconscious dispersal of the spores by insects, as are used by many flowering plants for the purpose of securing cross-fertilisation, also through the agency of insects."

**Aphelandra nitens.**—As a class the Aphelandras are, in common with many other Acanthads, remarkable for their showy blossoms, and so effective are several of them that it is impossible to say which is the best. In the front rank, however, stands *A. nitens*, whose flowering period is, like many of the others, not limited to any particular season of the year, yet at the same time it flowers more freely during the winter than at any other period. This feature is a great point in its favour, as bright colour is not conspicuous just now in the stove. Less apt to get bare at the base than some Aphelandras, this species with ordinary attention forms a well-furnished plant, clothed to the base with handsome shining foliage, deep bronzy green on the upper surface, and purple beneath. The leaves are oblong in shape, about 6 inches long and 3 inches broad, and of a firm, leathery texture. The flowers, borne like the others in an erect terminal cone-shaped head, formed of large adpressed bracts arranged in a four-sided spike, are bright scarlet, and, though the individual blooms do not last long, a succession is kept up from one head for a considerable time. This *Aphelandra* was first introduced by Richard Pearce—of tuberous *Begonia* fame—when travelling for Messrs. Veitch in South America. He found it in Muna, a province of Peru, and in the same district discovered the now well-known *Sanchezia nobilis variegata*. Soon afterwards he sent home *Begonia boliviensis*, and, later on, *B. Pearcei* and *B. Veitchi*, now in themselves but a name, while their progeny is represented in every garden.—H. P.

**To drive away moles.**—Moles are useful little animals, inasmuch as they destroy multitudes of wireworms and other obnoxious creatures, and no one wishes to destroy them without good cause, but they are very undesirable tenants of a garden. Throughout the winter we have been suffering from a plague of them. Last year trapping freed us for a time from their incursions on the tennis lawn, but in the autumn the brown heaps reappeared, and traps, with which no doubt familiarity had bred contempt, have been of no avail whatever. A remedy suggested some months ago by a writer in *THE GARDEN*, unless we are mistaken, occurred to mind, and the effect of pouring a little ordinary paraffin oil down the runs has been tried, in accordance with the advice then given, with the most perfect success. The nightly mounds have risen no more since the first, or, at most, the second application. The cheaper and

more evil-smelling the oil the better. By inadvertence some "refined Russian" at 8d. a gallon had been used for a garden lantern, with the result that the lantern suddenly burst—a warning not to be disregarded as to the danger of using a low-flash oil for any kind of lamp. But the remainder of the oil was quite good enough to use on the tennis ground, and the testimony that the plan answers admirably for the dispersion of moles may be of use to other readers of *THE GARDEN* who are similarly troubled. The never-tiring industry of the mole would be beyond all praise and much to be encouraged were it not too often in evidence in the wrong place, and it is just as well not to destroy it if it can be avoided.—K. L. D.

**Early flowers.**—*Saxifraga Griesbachii* was the earliest to flower this season. The first appeared on December 23, of *Rhododendron dahuricum* on the 4th inst., and that of *Winter Aconite* on the 9th inst.—T. SMITH, *Neury*.

**Gardening in the Antarctic regions.**—When the s.s. *Discovery* was taken to the Antarctic regions by Captain Scott, Messrs. James Carter and Co., High Holborn, London, conceived the idea of sending some seeds to supply the sailors with something green while passing the time frozen up within the regions of the Antarctic circle. An intimation of this was that the "only bit of green vegetable seen on the *Discovery* was a crop of Mustard and Cress grown by the officers on a wet blanket." This information was brought back to England by the relief ship *Morning*, and it shows that the officers had been successful in growing a little bit of green by following the instructions given by Messrs. Carter while passing the time in that dreary land. Another communication came through Admiral Sir Clements Markham, K.C.B., F.R.S., who heard that the Mustard and Cress supplied to Captain Scott of the s.s. *Discovery* was a great success and much appreciated. A further consignment of seeds, specially treated by an original process and packed in air-exhausted receptacles, has been taken out in the relief ship *Terra Nova*, which has lately left Hobart to seek for the whereabouts of the *Discovery*.

**Prunus japonica flore-pleno.**—This dwarf-growing *Prunus* is one of the most delightful of shrubs for flowering under glass early in the year; indeed, it is more valuable for such a purpose than in the open ground, as from the early season in which it naturally blooms the frosts and cutting winds often play havoc with the delicate flowers. There is no difficulty in getting it to bloom before the end of January in the greenhouse, and very attractive it then is, the slender branches being closely packed with comparatively large blossoms, like those of double Cherries, white in the variety *alba*, and slightly tinged in those of *rosea*. Large quantities of this plant are sent here from the Continent every autumn for forcing, but most of them are grafted or budded on the Sloe, the suckers from which are always a nuisance. Cuttings of the young shoots borne by forced plants will strike fairly well in a close propagating case, or an old plant or two may be layered out of doors. Plants intended for flowering under glass may be kept in pots for years if needed, being pruned back each year after flowering, and as soon as the young shoots have made a start pot them into good soil. This potting, however, need not be done annually if the plants are given liquid manure during the growing season. This Plum is often known by the name of *Prunus sinensis flore-pleno*.—T.

**Sparmannia africana.**—This is an old-fashioned greenhouse plant, and where a large structure has to be kept gay during the winter months, it is an extremely useful subject, but one whose merits in this respect are too often overlooked. Some fail to flower it well, this being in all probability the result of too free a growth, for the finest yield of bloom is obtained when the pots or tubs are full of roots and the plants thoroughly exposed to the summer's sun from July onwards. It may be grown as a bush or a standard, this last, I think, forming the most striking object when laden with bunches of white flowers, against which the large clusters of stamens (coloured purple and

gold) stand out very conspicuously. It is easily struck from cuttings, and a young plant soon forms an effective size. There is a variety with double flowers which about a generation ago was thought likely to be a valuable conservatory plant. It does not, however, flower so freely as the type, and is rarely seen. A second species which is very seldom met with is *S. palmata*, in which the leaves are lobed. It is altogether a more delicate plant than the other, and if stopped freely when young forms a neat bushy specimen that flowers as a rule during autumn. The flowers, which are borne in little umbels from the axils of the leaves, are about half an inch across. This is also a native of South Africa.—H. P.

## THE FRUIT GARDEN.

### RAISING BLACK CURRANT BUSHES.

**W**HY will nurserymen insist on raising Black Currant bushes with stems? No greater mistake could be made, as the great object is to get new shoots to grow out close to the ground, and if from the roots so much the better. Black Currant bushes bear chiefly on the wood of the preceding summer's growth, and it is therefore desirable to have as many new shoots each season as possible, so as to have the bushes so well furnished with them that as much as possible of the old wood may be cut out without disadvantage. When the bushes have long shanks, they become too lanky, and they are never as spreading as when there are no shanks. The cuttings should not be disbudded at all; then shoots will grow out from the buds nearest to the ground, which are usually the strongest, and some from buds under the ground. I have some young bushes grown from cuttings planted a little over a year ago, not disbudded, which are as big and branching as ordinary two year old bushes. In planting them out I cut them back severely, which will make them send out a number of strong shoots in the coming season. This is very important, and it is a serious mistake to leave the shoots of newly-planted bushes at all long. If allowed to fruit in the season of planting, by leaving the shoots long the bushes are permanently injured.

M. D., in *Agricultural Gazette*.

### VARIETIES OF THE BANANA.

THE frequent suggestions in the Press that other Bananas than the established Martinique variety should be grown in Jamaica, lead me to request the insertion in your *Bulletin* of the following reflections: First and principally, is it wise to make any change where the industry is so thriving? That there are Bananas superior to the Martinique in flavour is an undoubted fact. There are, however, several points to be considered before coming to the conclusion that it is desirable to substitute any one of these for the kind now grown. Market requirements are peculiar, and it does not follow as a matter of course that the best fruit gets a readier sale than the good. The public is conservative, and likes what it knows. Its eye is caught by appearances, and it wants something handsome. This is well exemplified in the Apple trade. Probably the most popular Apple in England is Blenheim Orange, and yet to connoisseurs it is not particularly good. In any market may be found lower-priced Apples of far better quality, which are neglected either because they are unknown or because they are less attractive in appearance.

Now no Banana is handsomer than the Martinique. Especially beautiful in the light yellow satin jacket of its perfection, it is also good to look at both before that stage and after it. Only when brown stains begin to disfigure the skin, whose hue has gradually deepened from light yellow to dark yellow, does it proclaim that it is no longer fit to eat raw. Even then it is excellent when cooked.

The Martinique keeps well, especially in cool climates, and a point in its favour is that it may

be eaten in several stages of maturity. Some people like it best when it has a slight tartness suggesting Apple, which is before the finger has become quite yellow. In this stage the skin screams if torn off rather quickly, and the flesh is fine and hard. Others prefer it when quite coloured, of an even light yellow all over. Others, again, like it in the more mellow state, when it has begun to taste like a sleepy Pear and its jacket has turned to a deep yellow. Not a few still enjoy it in the further stage, when more blotches begin to invade the skin. For my own part, that is a sign that it should no longer be eaten raw, and that it is in the best condition for the oven.

The original Banana of commerce in England is the China Banana. This, as grown in the Canaries, has a better flavour than the Jamaica-grown China. I do not think that even an undiscerning public would accept the Jamaica-China Banana. This is too coarse a fruit, and it would be a most dangerous experiment to attempt to substitute it for the Martinique.

On the other hand, some of the fine Indian kinds might be tried. They are of the highest excellence, decidedly superior to Martinique, though, as we have seen in the case of Apples, that is not necessarily a recommendation to the public. None that I have seen are as handsome in appearance. In any case, experiments of this kind should be left to the discretion of growers. Those who advocate new cultivations incur a grave responsibility. The great maxim of political economy, that progress is due to the pursuit of wealth by the individual, should never be lost sight of. The growing of a new fruit should be undertaken only because the grower is persuaded that he will make money by it. And the condition that he will succeed should come from himself, and not be forced upon him from outside.

Leaving market requirements, those who wish to have the best Bananas for their own eating should grow them upon the poorest soil. The small fingers of Martinique have a far higher flavour than the larger ones grown on good land.

WALTER JEKYLL, in *Bulletin of the Department of Agriculture, Jamaica*.

## TREES AND SHRUBS.

### THE ESCALLONIAS.

**T**HE genus *Escallonia* comprises about thirty species of half-hardy evergreen shrubs, of which about one-half are in cultivation in this country. They are all natives of South America, and thrive luxuriantly in the warm and genial climate of the south and west of the United Kingdom, but north of the Thames they can only be grown against a wall, except in a few favoured spots. It is a great pity, however, that the *Escallonias* are not hardier, as during the late summer and early autumn no outdoor plant gives such a pleasing display of flower as, for instance, a well-grown bush of *E. macrantha* or *E. punctata*. The cultivation of *Escallonias* is simple enough, any sort of soil seeming to suit them, though they will not thrive in cold or heavy ground, more, perhaps, because such localities are usually too bleak. They should not, however, be too well treated anywhere, a poor soil being best for them, as it keeps the growths short and firm, making them better able to withstand frost and damp weather, the latter of which often damages them as much as the former. In rich soils the plants grow faster, but they are usually found to be very soft in autumn, and fall an easy prey to the first sharp frost that occurs.

In most localities they will not require much pruning, being cut back, as a rule, by severe weather in winter, but in warmer parts an occasional thinning out of the growths is

necessary. This should be done in the spring, just as the plants are starting. At the same time any that are getting too large can be cut back within bounds. The following list comprises the best of the *Escallonias*, all of which are worthy of a place in the open garden or on a wall.

*E. eroniensis*.—This is a hybrid raised by Messrs. R. Veitch and Sons, of Exeter. It makes an upright shrub upwards of 6 feet high, and bears semi-pendent flowers of a pinkish white colour in great profusion. The leaves are ovate in shape, deep green, and very small. It is fairly hardy.

*E. illimita*.—This makes a spreading, much-branched shrub about 5 feet in height, and as much or more in diameter. The pure white flowers are individually small, but are in dense, terminal panicles all over the plants. The sticky leaves are oblong, crenulated, and covered with glandular dots on the upper surface. It is a rather tender plant, native of Chili, and requires the shelter of a wall in most places.

*E. langleyensis*.—This is a hybrid between *E. philippiana* and *E. macrantha*, raised by Messrs. J. Veitch and Son in 1897. The flowers are of a rosy pink or carmine colour and freely produced. The leaves are small, dark green, and shining. A fairly hardy plant, growing from 4 feet to 6 feet in height.

*E. macrantha*.—This is the commonest of the *Escallonias*, and is met with wherever they can be grown, generally under the names of *E. Ingramii* or *E. rubra Ingramii*. It makes a shrub 5 feet to 6 feet in height, and is one of the hardiest of the genus, or, what is perhaps more correct, it more quickly recovers after being damaged by frost. The flowers are bright crimson-red, rather large, and freely produced in terminal, racemose clusters. The leaves are ovate, serrated, deep green, and shining above, and dotted on the under surfaces. This is the best of the *Escallonias* with coloured flowers, and is wonderfully accommodating. I have seen old plants of this cut to the ground in the winter that have attained a height of 3 feet and been full of flower by the following September. It is a native of the island of Chiloe.

*E. montevidensis*.—This is a native of Monte Video, and is one of the most tender of the genus. Under favourable conditions it reaches a height of 8 feet to 10 feet, and bears terminal corymbs of pure white flowers. The leaves are oblong, and nearly or quite entire. The branches are sticky. *E. floribunda* is sometimes given as a synonym of this, but it is doubtful if it is correct.

*E. philippiana*.—This is a native of Valdivia, and makes an upright bush 4 feet or so high, with slender, twiggy branches, covered during July with small panicles of white flowers, borne both terminally and laterally in great profusion. The leaves are small, spatulate, and finely serrated, and are of a rich deep green colour. This is the hardiest of the genus, succeeding in the open in the London district.

*E. punctata*.—This shrub attains a height of 6 feet under favourable circumstances, though it is more often met with about 3 feet. The flowers are deep red in colour, borne in threes or fours in terminal clusters. The leaves are sessile, nearly ovate, finely serrated, and glossy with impressed veins on the upper surface, while the under side is variously smooth or dotted with tiny glands. This is sometimes confused with *E. rubra*, but is easily distinguished by the fewer and darker coloured flowers, and the stalked glands on the young shoots. It is a native of Chili.

*E. revoluta*.—This is a large Chilean shrub 10 feet or more high under favourable conditions, but as it is perhaps the tenderest of the genus, it is rarely seen in full perfection. The white flowers are in erect, terminal panicles or racemes, and open in August and September. The leaves are 1 inch to 2 inches long, nearly oval in shape, pubescent, and sharply toothed.

*E. rubra*.—This closely resembles *E. punctata*, but differs in the lighter red of its flowers, which are also carried for a longer period, and by the glandular hairs on the young shoots. It is a native of Chili.

All the Escallonias can be propagated by cuttings of half-ripened wood taken in August and put in a close frame. *E. langleyensis*, *E. macrantha*, *E. philippiana*, and *E. punctata*, however, which are the hardiest and also the best for general planting, can be struck outdoors in winter, using stout, well ripened wood, and planting the cuttings in a fairly dry, sandy spot.

Bagshot, Surrey.

## DECORATIVE CHRYSANTHEMUMS.

THE term decorative as applied to the Chrysanthemum is generally understood to mean varieties that

are free-flowering, bushy in growth, and bear flowers of pleasing forms and clear shades of colour. This definition may appear to some too comprehensive, while to others it may hardly seem to go far enough. As a matter of fact no hard and fast rule can well be laid down. What is really wanted are varieties that have a tendency to flower profusely, combining with this essential characteristic flowers suitable both for indoor decorations as well as for the conservatory.

The decorative Chrysanthemums as a class have been sadly neglected. At how many of the numerous Chrysanthemum shows held throughout the country in November are the decorative sorts exhibited? Very few indeed. Here and there, where the societies are ahead of their fellows, we see the small to medium-sized Chrysanthemums set up in pleasing contrast to the large blooms, with which we are now so familiar. In all cases where ample provision is made to set up the exhibits tastefully and effectively, the result is distinctly pleasing. Such a display illustrates the undoubted usefulness of the smaller flowers for the hundred and one uses for indoor decorations.

The societies that make the Chrysanthemum their special care are to blame for the present state of affairs. Their special object, as stated in their own rules, among other things, is to "promote the cultivation of the Chrysanthemum, &c." The success of the many Chrysanthemum societies has been very one-sided. At the November shows the large blooms, most of which are of Japanese origin, preponderate, and in a much smaller degree the incurred sorts; but large Anemones and Japanese Anemones are seldom represented, though they are the most quaint of the decorative section. At the great show of the National Chrysanthemum Society at the Crystal Palace, in November last, only 132 blooms of the large-flowered Anemones were set up in the competitive classes, and this in an exhibition of great magnitude. Pompons and singles were also poorly displayed, only seventy-eight bunches being staged. There were tables of decorative sorts embracing all types of the flower, in which sufficient space was not allowed by the rules of the competition to set up the bunches in an attractive manner. In other respects decorative flowers in the competitive classes were conspicuous by their absence.

The Chrysanthemum societies, to carry out the object for which they were instituted, should work upon broader lines. The large blooms should still be encouraged, but not to the exclusion of the decorative kinds. What could be more interesting and attractive than a series of exhibits in which the different types of these flowers, grown in a free style, could be displayed? Classes for groups and bush plants

would make effective contrast to those grown in the orthodox exhibition fashion to the advantage of the former. Other classes for a dozen or more bunches of Japanese kinds, either disbudded or partially disbudded, or separate classes for both, would illustrate some of the prettiest and brightest of the decorative varieties in this section. Other sections might be treated in much the same way, thus giving encouragement to quaint and curious large Anemone Chrysanthemums, of which far too little is known. The Pompons and singles deserve more consideration than they now get. Local and provincial societies are great offenders in this matter, and it is hard to believe they have any other object in view than the perpetuation of varieties developing big blooms.

The market growers have seen what the private growers have failed to appreciate. Ten years ago everyone was growing a few standard sorts, and the flowering time was short. What is the case to-day? From early October until the middle of January, and in several instances still later, the display is maintained. The flowers are beautiful in colour and form, and the market men, by a careful selection of suitable sorts, have now an excellent series of decorative varieties, and if these could only be displayed at some of our London and provincial shows, what a splendid object-lesson their exhibition would be. It is all the more gratifying to learn that there is the prospect of a display in late December of this year, or in January of 1905, of decorative Chrysanthemums, by the National Chrysanthemum Society. The market men have taken the matter up, and there is reason to hope that much good will be brought about through their efforts. Chrysanthemum societies are now making up their schedules for next autumn's display, and for this reason these remarks may be considered opportune.

Highgate, N.

## NOTES ON HARDY PLANTS

### ANEMONE SYLVESTRIS.

ONE of the first hundred plants figured in the *Botanical Magazine*, this elegant little plant has been an inhabitant of our gardens since the end of the sixteenth century, when it was introduced into this country from Germany. The popular name "Snowdrop Anemone" was suggested by the drooping habit of the flower-bud before fully expanding, giving it a certain resemblance to that well-known flower. Although generally found growing in shady places in its native habitats, it is not particular in its requirements in cultivation, doing well and flowering freely in most situations and in any good loamy soil; but it succeeds best in a light rich soil, which contains plenty of decayed vegetable matter and in a moist and shady situation. It is easy to increase, as it has creeping roots which it extends on every side, throwing up numerous suckers, which may be divided from the parent plant when necessary for the purpose of propagation.

In common with many other Windflowers, the good-sized white flowers, 1½ inches in diameter, are borne on long peduncles, which arise singly from an involucre of leaves. These leaves are ternate or quinate, with deeply-toothed leaflets, hairy on the under surface. Sometimes two flowers are produced from one involucre, but it is not a frequent occurrence. The accompanying illustration shows the value of the cut flowers for decorations, as they last in water for some time, but they are far more charming when growing naturally in tufts, attaining a height varying from 9 inches to 15 inches, covered with many flowers in April. After these are past their place is taken by little woolly heads containing the seed-

THE SNOWDROP WINDFLOWER (ANEMONE SYLVESTRIS).

(From a photograph kindly sent by M. Corvecon, Floraire, Geneva. The flowers were gathered on the Alps.)

Having a wide distribution, which extends over the central countries of Europe, from France to South Russia and Thrace, this species is also found in the Caucasus. *A. sylvestris* flore pleno is a form with double flowers without the elegance of the type, and frequently having a green centre. A closely-allied plant is the *A. baldensis* from the Alps and Pyrenees, with more tuberous roots, more finely divided leaves, and smaller white flowers tinged with red on the outside.

W. IRVING.

#### DAPHNE GENKWA.

To the superficial observer this appears to be a Lilac, that is to say, during the flowering season. Its natural season out of doors is in April or May, but under glass it will readily flower in January or February. At that time leaves are absent, the leafless branches being studded with loose clusters of flowers, which, as above stated, are much like those of the Lilac. The individual flowers are about half an inch long, and much the same across the petals, which are four in number. The colour of the flowers is a very pleasing shade of bright lilac. *Daphne Genkwa* can scarcely be regarded as thoroughly hardy, for in the neighbourhood of London it succeeds best with the shelter of a wall. It was, I believe, originally introduced by Robert Fortune, but was for a time afterwards almost lost till we were in more ready communication with Japan.

H. P.

#### NYMPHÆAS OF THE ODORATA GROUP

The only *Nymphæa* of this group in my small Lily tank—*sulphurea grandiflora*—was planted there in 1897, and is now behaving precisely in the unsatisfactory manner described by Mr. Greenwood Pim in THE GARDEN of the 16th inst. It bloomed magnificently as soon as it got established, and did well until about two years ago, when it began to go to the bad. During the last two summers few

buds have appeared, and these have failed to expand properly, while the foliage has been very weak and scanty. I propose to remove it altogether this spring and put in something more permanent. The other two *Nymphæas* in the tank—*N. Marliacea albida* and *N. Laydekeri rosea*—planted at the same time are flourishing.

S. G. REID.

#### SOME OF THE CELMISIAS

The *Celmisias* form a very interesting genus of Compositæ, closely allied to *Aster* and *Eri-*

*geron*, and confined to New Zealand and the adjacent islands, one species being said to extend to Australia. Upwards of thirty species have been described, thirty-four being given in the "Index Kewensis." Of these a few have from time to time been introduced, but, through the difficulty experienced in their cultivation, they have never become well known, and they are rarely met with. The majority of the known species are described in Sir Joseph Hooker's "Handbook of the New Zealand Flora," and from the descriptions many of them must be very ornamental. The accompanying illustrations show what beautiful objects many of these *Celmisias* are when growing under satisfactory conditions, and if we could solve the problem of their requirements, so as to grow them into such fine specimens as shown here, they would prove extremely valuable for the garden. The great drawback to their successful cultivation in this country is the fact that they are not sufficiently hardy to withstand the winter out of doors, except in favoured localities, while pot culture seems distasteful to them. Good plants have occasionally been grown out of doors, especially *C. coriacea* at Glasnevin. Under natural conditions the *Celmisias* are found in mountainous regions up to an elevation of 5,000 feet above sea level. They grow chiefly among rocks, and are often found in the vicinity of water, the rocky banks of rivers, &c. They are all low-growing herbs, with a thick, woody rootstock and numerous radical leaves, which are usually covered with a silvery or brownish tomentum. The Daisy-like inflorescences are on long, silky stalks, and in the different species vary considerably in size, some being but an inch or so across, while others are quite 3 inches in diameter. The ray florets are usually white, the disc yellow, but

CELMISIA RAMULOSA IN A NEW ZEALAND GARDEN.

CELMISIA CORIACEA.

in a few instances species are recorded with lilac ray florets. The following species are occasionally met with, the dimensions of leaves and flowers being those given in the recorded descriptions :

*C. coriacea*.—This, as seen by the illustration, makes a low, spreading mass. The leaves are from 10 inches to 18 inches long, and from half an inch to 2½ inches wide, lanceolate in shape, and thick in texture. The under surface, together with the stalks and peduncles, is covered with a thick, cottony tomentum ; the flowers are borne in heads 1½ inches to 3 inches in diameter on long peduncles, the ray florets being white, and the disc yellow. It is said to be abundant in the mountains from Nelson to Dusky Bay.

*C. Haastii*.—A strong-growing species with large leaves, which are less woolly than the foregoing. The flower-heads are on short, sturdy peduncles, and are from 1½ inches to 2½ inches across.

*C. Lindsayi*.—A figure of this is given in the *Botanical Magazine*, t. 7134. It makes a dense tuft of leaves 3 inches to 6 inches long ; they are lanceolate, coriaceous, and white on the under surface. The peduncles are about 6 inches high and the flower-heads 1 inch to 2 inches across, the ray florets being white.

*C. Munroi*.—This was introduced about eight years ago. The leaves are linear-lanceolate, about 5 inches long, dark green above, and covered with a white, silky tomentum beneath. The ray florets are white, the disc yellow, the heads being about 2 inches across. A figure is given in the *Botanical Magazine*, t. 7496.

*C. ramulosa*.—As seen by the illustration this makes a dense mass, the leaves being small and short ; the flower-heads are on short stalks, and are about an inch across.

*C. spectabilis*.—It is about twenty years since this was introduced. In habit it is very similar to *C. Munroi*, the leaves being of much the same size and colour. The flower-heads are about 2 inches across, and the ray florets may be white or tinged with lilac. W. D.

## RARE EXOTICS IN ROSS-SHIRE.

MR. MACKENZIE sends the following extract from the *Glasgow Herald*, and asks for its insertion in THE GARDEN. The notes are of much interest, and we gladly publish them.

My last floral notes consisted of an account of my trees, shrubs, and herbaceous plants in 1901.

The year 1902 was a bad year from a horticulturist's point of view. With a severe winter and a worse spring, followed by an ungenial summer, it was most disappointing. Still, it may interest my readers to hear that I had hardly any losses among my many hundreds of rare exotics.

I nearly lost one of my Dicksonias (Tree Ferns), some of my pretty pink *Cistus crispus* died, and also my big bushes of *Veronica Andersoni*, and that was about all ; and in spite of the bad year I had some great successes. Even during that terrible February snowstorm, when the snow lay deep right down to high-water mark for nearly the whole month, my bush of Japan Witch Hazel (*Hamamelis zuccariniana*) was in full bloom, its curious small golden blossoms with crimson filaments looked lovely sparkling in the sun, with the snow as a background.

Later on among startling plants were *Azalea Vaseyii*, a Japanese species with soft lilac blooms, and *Andromeda formosa*, which astonishes everyone, being a glorified *Andromeda japonica* ; and as the season advanced, after reading an account of the blooming of *Abutilon vitifolium* in the Scilly Isles, my own big bushes, some 6 feet or 8 feet high, blossomed profusely. It was a great triumph. They are about four or five years old, and were

raised here from seed procured from the late Mr. Thompson, of Ipswich, and their large hanging bunches of mauve flowers were glorious. This thoroughly hardy *Abutilon* is a shrub which has, I think, a great future before it.

Some of the new Escallonias were very taking, such as *Langleyensis* (red), *Exoniensis*, and *Pterocladon* (white), and are all real acquisitions.

For the first time I bloomed *Kalmia latifolia*. I was beginning to think that it was one of the plants which was going to beat me, and therefore one that I had particularly set my heart on flowering, when all of a sudden one of my plants appeared smothered with buds, and how lovely they were when they expanded !

The eight new *Azaleas* (crosses between *mollis* and *indica*) came quite up to Van Houtte's description of them. They were dazzlingly gorgeous in June, and are as hardy as *Azalea pontica*.

*Cydonia Columbia* I can thoroughly recommend as a bedding shrub ; it is as brilliant as a *Geranium* and as hardy as a *Beech* ; and, lastly, my little *Desfontaineas* gave me great satisfaction. One of them bloomed a second time at the beginning of December, and its long scarlet and orange tubular flowers are so firm and waxy, and, being also protected by its glossy evergreen prickly leaves, no amount of rough weather seemed to injure them. How magnificent they are at Pottaloch, 8 feet high, and broad in proportion, and smothered in bloom. The growth is so like the European Holly that it is sometimes called the Chilean Holly.

And now I have, perhaps, said enough about poor 1902, which, I confess, got more abuse from us gardeners than it deserved, and we will see what can be told of 1903.

At the risk of repeating myself, I must speak of the beauty on last New Year's Day of our famous Tulloch variety of *Rhododendron nobleanum*. It is the most perfect of winter-flowering shrubs, for even if the weather be atrocious, as it was last January, if the sprays with the crimson buds are cut and put in vases in the house they expand to perfection.

We had naturally not much in bloom on January 1 of this year, except *Polygala Chamaebuxus* and *Lithospermum prostratum*, which was a sheet of blue, and evidently imagined it was still on its native rocks on the shores of the Bay of Biscay instead of on the shores of the Minch.

In March the first of my twelve new species of *Rhododendrons* bloomed, viz., *R. ciliatum*, and very pretty it was, with its large pale pinky white bell-shaped flowers ; it was only a tiny plant, 1 foot high, but smothered with blooms, which seemed almost too big for it, and just as it was fully expanded I left for Italy, and saw no more of my shrubs till the beginning of June.

From all accounts the spring of 1903 was quite as bad as that of 1902, only in a different way—viz., perpetual hurricanes of wind, with torrents of rain, which caused as much harm as the hard

weather of the previous spring. Curiously, on my return, the Scotch Firs showed more damage than any of my five species of *Eucalyptus*, which must be hardy to a degree. There is certainly something radically wrong in the modern *Pinus sylvestris*, as, instead of being one of the hardiest, it is one of the worst to stand gales and sea blasts.

I returned just in time to see the finish up of my *Trilliums* and *Erythroniums* ; my gardener told me they had been really grand, and I found a new kind of *Trillium*, with recurved petals of a deep pink, which much fascinated me.

My show plant in June was my big *Crinodendron hookerianum*, about 7 feet high, and the only plant I can boast of as being better than the one at Castlewellan, that garden of gardens in County

CELMISIA HAASTII.

Down. After seeing Lord Annesley's collection, my attempts here appeared very feeble indeed, and my *Crinodendron* was the only thing I could venture to brag of before his lordship.

Well, my *Crinodendron* was just covered with its crimson Chinese lanterns, hanging by long thread-like stalks, a most striking bush ; *Rhododendron racemosum* from Yunnan, where it grows at a height of 10,000 feet ; *Kalmia rubra* and *Erica arborea* were among the most telling on my return home. The first-named of these three would not, I think, be easily recognised as a *Rhododendron* by an ordinary observer.

My big *Erica australis*, alas ! I found dead. I had unfortunately shifted it before leaving, and it is a lesson to me not to transplant tall Heaths. Two *Deutzias* were also striking in June, viz.,

*D. corymbiflora* and *D. discolor purpurea*, and they are well worth getting.

I was glad to find that my *Mutisia decurrens* had stood both winters all right, and both last year and this it has flowered nicely, and though a Chilean by birth it has a South African old-world look about it, and one might mistake it, with its Orange-red stars, for a climbing cross between a *Gazania splendens* and a *Gerbera Jamesoni*. Two species of *Metrosideros* have stood out with me several winters, the one, which is the famous *Rata* of New Zealand, has not yet flowered, but the Australian one has given us a small sample of its crimson bottle-brushes.

My hardy deciduous *Magnolias* are too young for me to be able to say much about them; but I had a very few blooms this summer on *M. Lennei* and *M. stellata*, and I hope for great things from them if I live a few years longer.

from my garden, where it had never been a success in the hot shingly soil, and planted an edging of it to one of my walks in my shrubbery, which I call Japan, in raw, cold, peaty soil, and there it has proved a complete success, and has bloomed profusely this summer. In the same manner the Chilean *Mitraria coccinea*, with gorgeous vermilion flowers like miniature bishop's mitres, which only struggled for life in the garden, has grown into a charming little shrub in my Japan; also *Philesia buxifolia*, from Magellan, just a dwarf bushy *Lapageria rosea*, is beginning to look quite happy with its present surroundings. And this system of changing I mean to continue, as I have still a few things that defy me, such as the so-called New Zealand Broom (*Notospartium Carmichaeliae*), which does so well in that delightful home of rare plants, Loch Hourthead; and the *Carpentaria* and *Encryphia*, which I do not grow to perfection

tinue my tale at some future time, when I have further experiences to recount.

O. H. MACKENZIE, F.R.H.S.

*Incurva, Pooleri.*

## IN A SUNNY LAND.

A BROLLING, dusty road, a low stone wall with purple *Iris* growing on top, further on hedges of Christ's Thorn (*Paliurus australis*) with cruel prickles, making it hard to gather the first rosy flowers of the spring *Cyclamen*, which hid and clustered among the silver-striped leaves of Dead Nettle, then the cool shade of a Cypress avenue, and we were treading on classic ground. How often it comes back to memory that red-letter day in March spent

CYPRESSES AT TIVOLI: IN THE RUINS OF HADRIAN'S VILLA.

The New Zealand Tea Bush (*Leptospermum scoparium*), which is, I am told, as great a plague in Maoriland as the Braeken is in the Highlands, seems quite hardy here, blooms and fruits freely, is very pretty, and quite aromatic when handled. New Zealand and Chilean things certainly suit this damp climate.

Perhaps my greatest achievement this year has been the flowering of *Buddleia Colvillei*. I have two big bushes of it, and one of them produced three sprays of blooms, and when I first noticed it I thought a Foxglove (of which I have many in my shrubberies) had been allowed to grow up among the stems of the *Buddleia*, but on examination I soon saw that it was not a *Digitalis*, though the handsome purple blooms rather resemble a Foxglove or a Pentstemon.

I find that when a plant is not a success the great thing is either to shift it to entirely other surroundings or buy another specimen and try it elsewhere. Last autumn I removed a lot of *Heuchera sanguinea*

yet, though I have bloomed both here; and the *Berberidopsis corallina*, which flourishes so on Inveree House, on Loch Nevis, and several other charming exotics, which I mean to master in course of time.

For the end of October and November, when flowers in the shrubberies are scarce, let me recommend the *Spartinum*, or Spanish Broom, and the white Irish Heath (*Menziesia polifolia alba*): the latter covers my ground in masses, and is at its best in November; and with these and with *Enkianthus japonicus*, a most charming new Japanese shrub, whose leaves turn a dazzling vermilion, no one need complain of dull shrubberies in late autumn. *Lilium auratum* and *lanceifolium rubrum*, and more especially *Crococsmia imperialis*, dotted about among the summer-flowering shrubs, give also a lot of brilliancy to the "fall," as our American cousins call it.

But my story has perhaps been too long, and I cease at present, but only with the hope to con-

on the spot here illustrated. The colossal ruins of Hadrian's palaces, roofless, silent, bathed in golden light and beautiful in decay, spoke eloquently enough of the vanity of human greatness. Sitting to rest on the broken steps of an over-arching portico, gladly we turned our faces from the fallen past to the joyous living present. Scarcely a leaf was stirring. Not far off the mighty spires of a group of Cypresses rose dark against the cloudless blue, solemn, immovable, impressive beyond words, living sentinels standing guard over the relics of the Imperial dead. Below them—a lovely contrast—a sea of grey-leaved Olives, and under the Olives Violets—tens of thousands of Violets—in such amazing drifts of royal colour, and breathing into the warm air such delicious fragrance as seldom comes to one but in dreams. Had

we ever seen Violets before? Or have we ever seen them since? No modest, humble flowerets these, hiding lowly under their sheltering crowns, but strong-stemmed and open-eyed, holding up their heads well above their leaves, and perhaps—yes, just a little flaunting withal. Nevertheless, how lovely they were. What handfuls we gathered, and what would we not give to see the like under the trees in our own garden at home. Other flowers were there as well. Starry Anemones, lavender and white; and stretches of Bugle, not coarse and of no account as we deem it, but dainty and choice with tall spikelets of azure blue. Bushes of Coronilla, too (*C. Emerus*), great bosses of shining gold, grew everywhere. Not the pale-flowered sea green form, which does its best to light up our dull November days, but full-coloured and bright, setting its foot high and low; now happy on the sod, clustering about the bole of some ancient Olive; now in mid-air, clinging in glee to the sunburnt brickwork of ruined pavilion and palace, and laughing at our vain attempts to reach it. A few belated Crocuses still lingered on the grass, but here and there *Romulea* was taking their place, and stained the green sward with patches of purple and orange. And over it all the canopy of an Italian sky and the undimmed glory of Italian sun.

We long, sometimes, to transplant such memories and live them over again in our own land. Like greedy children we want to hug to our own selfish, English heart all the delights that belong by right to other peoples. But it is vain and useless. Far better to let them be memories, and to take with thankful content the treasures that are ours.

These Cypresses for instance. Here and there, though rarely, in stately English domains we do find groups which were planted long ago, admirably placed with regard to both shelter and prospect, and finely grown. But they are Southern trees, no more indigenous, indeed, to Italy than they are with us, and though they may be found everywhere to-day, from the foot of the Alps to Calabria and Sicily, all historic allusions go to prove that the Romans themselves had to acclimate and cultivate them with care and difficulty. It is a tree whose chief affinity is with sun-lit plains, and therefore cannot withstand great rigour of climate. An exceptionally cold English winter may kill or seriously cripple it. And then—how slow of growth! It is impossible to tell how many centuries it has taken to build up those solemn pillars whose fluted shafts tower upwards, sometimes more than 100 feet. Those said to have been planted by Michael Angelo in the cloister garden—it is so no longer—of the old Carthusian Monastery in Rome, certainly do not impress the beholder by reason of

their great size, though presumably they are at least 400 years of age. Columnar trees, besides, must be planted with the greatest judgment, and seldom suit the character of our more Northern landscape. And how is it possible to reproduce the glamour of the sunlight and clear atmosphere which lend them in other lands more than half their charm? But one cannot dog-

## GLADIOLI IN QUEENSLAND.

I NOTE in THE GARDEN that you are interested in what is being done in other parts of the world besides Great Britain, so I am taking the liberty of forwarding you a photograph of a *Gladiolus* that originated with me. It was carried into the town in the sun before being photographed, and is in no way touched up. The photograph is half full size, so that you will see the individual flowers are 6 inches across. The colour is also pleasing, being pale pink, lightly flaked scarlet, white blotch, spotted carmine. It is an early flowerer, rather dwarf, and very free. I have now been raising *Gladioli* for about ten years, starting with selected French strains of *gandavensis* and *Lemoinei*, and adding *Childsii*, and it was from the latter cross that the *Gladiolus* described came. I called it *Kitchener*. I have now some very fine varieties with large, well-opened flowers and massive spikes. One variety grew this year 6 feet 6 inches high. Latterly I have been raising *Hippeastrums*, but have a difficulty in getting really good varieties to start with, and catalogues do not give descriptions, which seems a pity, especially to those at a distance. There are advantages in raising these here, as I have had flowers in one year from seed, and always in two, and the increase is rapid.

## ROSE GARDEN.

### SOME BOURBON ROSES.

MRS. BOSANQUET.

IT is always rather a moot point whether this variety ought to be classed among the *Chinas* or the *Bourbons*, but the general opinion seems to be that it belongs more to the latter class. Though an old Rose, seeing that it was distributed for the first time in 1832, it is still quite worthy of ranking among our best garden varieties. M. Laffay, to whom we owe this variety, was one of the pioneers of that band of French rosarians who have done so much towards the enrichment of gardens the world over.

This same raiser also gave us the well-known *China Rose Fabvier* the same year as *Mrs. Bosanquet*, and, if these two varieties do not suffice to keep his memory green, there are several other good old sorts from the same source, such as the *Boursault Amadis*, *Coupe d'Hebe*, the

two *Moss Roses*, *Laneii* and *Perpetual White*, all of which are still to be found in many gardens, and, in their several ways, are still of value.

But of all Laffay's introductions none surpasses the variety which heads this note, and I am drawing special attention to it here because it is getting overlooked in the rush for novelties, many

GLADIOLUS KITCHENER. (From a photograph sent from Queensland.)

matise too much. Only it is hard to restrain a smile or a sigh—one scarcely knows which—when one sees such a tree as the evergreen *Cypress* huddled, in company with other trees of like noble aspirations, within the scanty limits of the few square yards of a forecourt garden.

K. L. D.

of which are far behind it in true garden value. I remember a few years ago, when spending a day or two at Worcester with that enthusiastic and skilful exhibitor, Mr. E. Foley Hobbs, how I was more charmed with a large standard of Mrs. Bosanquet than anything else in the garden. It was a splendid example of a standard Rose, being good in shape, and simply covered with dozens of delicately-tinted, flesh-coloured buds and flowers. This Rose is a perpetual bloomer, and, unlike many of the Bourbons, is quite as good in early summer as it is in autumn. The semi-drooping flowers are fragrant, globular, perfectly double, and are sometimes really large, while they stand bad weather well. Moreover, the variety is perfectly hardy, and a half-standard in this garden, though in a terribly cold and draughty position, always proves satisfactory, and flowers from July to the frosts. About seven or eight years ago a quite pure white sport from this Rose was distributed by C. Freundlich, but never seems to have been introduced into this country.

#### MARIE PARE,

distributed by M. Jamain in 1881, is a seedling from Mrs. Bosanquet, very free in bloom, and slightly deeper in colour than its parent. It is really astonishing how little known are some of these old Bourbon Roses, and even now both amateurs and raisers might well give this family a little more attention. Messrs. Paul of Cheshunt have given us two most valuable varieties in Mrs. Paul and J. B. M. Camm, but these, like the ever-popular *Armosa*, scarcely come under the category of little-known Roses, because all are widely grown and appreciated in this country. Reference has been made quite lately to

#### MME. ISAAC PERIERE,

and I am happy to endorse all that has been written about it. Even in this light soil it grows to perfection, and in a neighbouring garden I saw it during early November covered with fine blossoms and rambling up the trunk of a dead tree.

#### SOUVENIR DE MALMAISON,

sent out as long ago as 1844, and its climbing form, which appeared almost exactly fifty years afterwards, are both grand autumn Roses, and it is a great pity that their summer blooms should be so deficient in form. Both make large standards, and prove very hardy in this district.

#### COMTESSE BARBANTANNE,

sent out by M. J. B. Guillot père in 1858, is another useful old Rose, which I came across quite recently. It is a true Bourbon, and has pale salmon-white fragrant flowers of good form.

#### BARONNE DE MEYNARD

(not Maynard, as it is frequently spelt) should also be classed as a Bourbon, and is a valuable white Rose of good shape but little scent.

#### MME. ERNEST CALVAT,

recently referred to by Mr. E. H. Woodall, is also a Bourbon variety, and was distributed in 1888 by Veuve Schwartz, successor to J. Schwartz of Lyons. It is a singular sport, I am informed, from Mme. Isaac Periere, and seems to be fairly well known on the Continent, though never met with in England. The colour is extremely variable, China rose or lilac-rose edged with yellow.

#### ZEPHERINE DROUIN.

A Rose which has more than half-a-dozen synonyms ought surely to be good, and, as regards the above variety, this is certainly the case. Here are a few of the names under which I find it described in Continental catalogues: *Zéphirine Doingt*, *Zéphirin Drouan*, *Zéphérine Drouot*, *Zéphyrine Drouot*, *Zéphyrine Druot*, *Chas. Bonnet*, and *Mme. Gustave Bonnet*. According to Messrs. Nabonnand the correct name is the one which heads this note. This Rose was distributed in 1858 by a Dijon nurseryman named Bizot, and it seems extraordinary that, considering its great popularity abroad, nearly all our English growers omit it from their catalogues. The last synonym—*i.e.*, *Mme. Gustave Bonnet*—is apt to be misleading, because a Rose of this name, belonging to the *Noisette Perpetuels*, was sent out by Lacharme in 1865, and has not yet dropped out of cultivation.

But whatever its name, this is certainly a Rose for our climate, as the flowers open easily and are not affected by wet. As recently noted in *THE GARDEN*, under the name of *Chas. Bonnet* (page 328), it is deliciously but not strongly scented, and a bush in a friend's garden this season has proved very free. The wood is very smooth, and quite as free from thorns as *Mme. Bérard*; the flowers are rosy crimson, and, like those of *Mrs. Bosanquet*, of semi-drooping appearance, while the foliage is dark green and very persistent. It does well when grown upon its own roots. One can but hope that some of these old Bourbon Roses, neglected as they now are, will not be allowed to drop altogether out of cultivation; for many things can be said in their favour, and among their number are several which will grow and flower in situations where the *Teas*, *Chinas*, and even *Hybrid Perpetuels* refuse to thrive. The National Rose Society might do worse than provide a class for Bourbon Roses at their September show next year.

Worcestershire.

ARTHUR R. GOODWIN.

### AUTUMN-PLANTED CUTTINGS.

A LARGER percentage of rooted cuttings would frequently result from those planted in autumn if means were taken to protect them from frost in winter and spring. To achieve this object in winter a good thickness of leaves spread over the whole ground is the best plan one can adopt, but they must be secured by strings or sticks or they will be scattered by the winds. Failing leaves then *Bracken Fern* strewn over the cuttings is the next best thing, and the sooner this is done the better. It is not that the cuttings are tender, but the action of frosts lifts them several inches out of the ground, and rarely can they be put back as they were originally. In spring evergreen boughs form a good protection if these are cut up into rather short pieces and arched over the rows in order to protect the tender growth from spring frosts. P.

## THE INDOOR GARDEN.

### NERINES.

ON the 8th inst. we cut the last of our *Nerine* blooms, after a most successful flowering season, extending over four months, fully 90 per cent. of the bulbs flowering, a fact which has amply repaid us for the little time spent on their cultivation. No other genus of flowering plants can be compared with this for its adaptability, its most easy culture at practically little expense, and yet it is seldom seen even in large gardens. *Nerines* are more easily grown than the majority of South African bulbs, as they can and will grow readily in a frame where frost can be excluded. At the time of writing a batch of seedlings planted out in a cold frame are growing to perfection, and which we hope to flower a season earlier than when grown on in pots. Those in pots are now in full growth, and should be looked over about twice a week for watering purposes. Those that were not re-potted last autumn would benefit by an occasional dose of weak liquid manure. Avoid giving them too much, as they are more liable to shrivel during their resting period. In careful watering at this period of their growth lies the whole secret of success.

W. H. WALTERS.

*Colesbourne Park Gardens, Cheltenham.*

### CYCLAMEN PERSICUM GIGANTEUM.

#### CULTURAL HINTS.

ALTHOUGH the proper season is past for obtaining the best results in the culture of this beautiful winter-flowering plant, nevertheless seeds of a good strain may now be sown for affording

flowers twelve months hence, but those who have them already up will, if due attention is paid to details, gain a decided advantage. No one could fail to admire those shown by Messrs. Hugh Low and Co. at the last meeting of the Royal Horticultural Society. Some six weeks ago, before we started cutting our flowers (and when mention was made of them in *THE GARDEN*), we could have staged 200 plants of equal merit.

#### SEED SOWING.

Seed should be sown early in August, when solar heat is an advantage to quick germination; this should be for the main batch. Another sowing at this date will also prove useful, especially for growing on the second year after slightly resting the corms after flowering; but by sowing in August a good specimen is obtained by the following November, and lasts well into March. For the sowing of the seeds pans or large saucers (provided they have holes in the bottom) should be procured, and filled with soil to the depth of 3 inches or 4 inches. It should consist of equal parts of good mellow loam and decayed leaf-mould, grit, and a liberal addition of silver sand, with a little charcoal dust added. Put the whole through a fine-meshed sieve. The seeds should be placed quite 1 inch apart, as this saves pricking them off, and be covered slightly with fine sandy soil, sprinkling them several times over with a fine rose can. Water will be best given after this by immersing them in a tank of soft water, keeping the rim of the pan or saucer just above water until bubbles cease to rise. All the soil is then saturated. Two or three such waterings generally suffice during germination, but any intelligent person can easily discriminate by lifting the pan as to whether water is required. From the time the seeds are sown until a couple of leaves appear the pans should be covered with sheets of glass, and shaded during bright sunshine with light paper, giving them cool pit or greenhouse treatment where plenty of light can reach them. The period of germination generally extends from six to eight weeks. The seeds being up and glass removed, they should be gradually inured to the sunlight, placing them upon a shelf near the glass, giving them a close and moist atmosphere, slightly spraying them several times a day.

#### FIRST AND FINAL POTTING.

About the middle of November they should be placed in small 3-inch pots, using a similar compost to that for the seed sowing. Place them upon the shelf of the stove or any house with a brisk heat and plenty of moisture, spraying them with soft water, if procurable, several times a day until the cold weather sets in, when twice a day will suffice. About the end of January they will require another move, which should be into a large 3-inch pot, using similar soil and affording them the same treatment until March, when the smallest corms should be given 4½-inch pots and the larger 6-inch pots. The soil for this should consist of two parts good yellow loam, one part half-decayed leaf-mould put through a ½-inch mesh sieve, the loam being broken by hand to about the size of a Walnut; add half a part of dried cow manure, with a similar quantity of burnt earth and old mortar rubble combined, with a good sprinkling of silver sand and a slight sprinkling of fine charcoal, and mix the whole thoroughly together. The pots should be carefully crocked, placing upon the crocks a little soot, taking care to put some rough material, such as fibre from the loam, to keep the drainage clear. After being potted, place the plants in a little warmth and keep close, and lightly spray occasionally, shading them during bright weather until established, always keeping them as close to the glass as possible.

The aim should be to get the corm as large as possible, with plenty of roots and foliage, and the flowers are sure to come, provided the strain is a good one. They should be gradually hardened and brought to cool treatment as the weather permits, giving plenty of air on all favourable occasions. Avoid cold winds by opening the ventilators on the opposite side to which the wind is blowing. Always use soft rain-water, and spray with it also, which should be done often in hot weather. Keep

a tank in a sunny spot for the purpose, and use a light tiffany shading rather than mats during the brightest hours of the day. When the sun begins to decline in the afternoon they may be syringed and shut up, gradually opening the house a few hours afterwards. This induces quick growth. Give them a watering of guano water or Clay's, at the rate of a tablespoonful to the four gallon can, once a week; house them before the severe weather sets in, and place them as near the glass as possible, giving them plenty of room. Some of the best of the varieties may be selected and grown a second year.

C. J. ELLIS.

Warren House Gardens, Stanmore.

## LILIES IN A TOWN GARDEN.

FROM time to time most interesting notes on Lilies have appeared in THE GARDEN, but chiefly from those who are favoured by good and suitable soil and agreeable atmospheric conditions. There are, however, probably many readers who are not so fortunately situated, but are obliged to make the best of a poor soil and such weather as prevails in a suburban district. But even with such drawbacks it is possible to grow very successfully some of the Liliaceae. My experience with their culture in a town garden has not been a long one, but so far I have obtained sufficient results to warrant my trying more sorts. No garden ought to be without Lilies, in even the most unsatisfactory garden a few of them can be made to grow, if they are treated with intelligence and reasonable care.

It is best to begin with a few of those notoriously easy of culture, and gradually to pass on to those more difficult. There are few plants that give more pleasing results for the same amount of trouble than the most robust of the Lilies. Provided they are carefully planted, they need practically no further attention. I do not say that they would not benefit by it, but they do extremely well without it, and this is a point to be considered by those who garden under great disadvantages, both as to soil, situation, and time at disposal.

My soil is similar to that of most town gardens, heavy and poor; in fact, such as would grow very few plants well if it were left alone. The soil gets very wet during winter, for the borders are not properly drained and the subsoil is clay. However, in spite of these disadvantages I have managed to grow some Lilies very successfully. In the first place, all the borders were deeply dug and some manure mixed with them in the autumn. Then where the Lilies were to be planted I again dug the soil, mixing in plenty of sifted ashes, which, of course, are very easily obtained. This was all the preparation given to the borders. When planting the bulbs I made large holes, placing in them a good quantity of rough sand, which I incorporated with the soil. I practically embedded the bulbs in sand, and also mixed a good deal of it with the soil immediately surrounding the bulbs. I paid due attention to the requirements of each Lily as to whether they made stem roots or not, and planted them deep or shallow accordingly. For instance, the following root from the stem as well as from the bulb: *Auratum*, *longiflorum*, *speciosum*, *tigrinum*, *Hansonii*, *croceum*, *Brownii*, and *elegans*, while *chalcedonicum*, *pomponium*, *candidum*, and *Martagon* do not.

I planted the bulbs in January, simply because I received them late; but I believe it is much the better plan, where the soil is heavy and likely to become very wet during winter, to plant in January or February rather than in the autumn. Some bulbs I have recently taken up were partly decayed, but we had an exceptional amount of rain last autumn, which has doubtless made them worse.

The Lily that has done best with me is *L. croceum* or *umbellatum* (the Orange Lily). This one would have expected, for it seems to thrive anywhere. The first year it was good, but the second year it was much finer, and I am hoping that this year it will be better still. Although it grows so well and is so common, it should not be despised on that account, for the deep orange, cup-shaped blooms are very handsome, and, provided the plants are not exposed to the full sun (although this does not appear to affect their well-being) the flowers will last a long time in beauty and give a good succession. I believe this Lily would grow in the most ordinary garden soil without any preparation of the latter,

but there is no doubt that a little help is appreciated. *Lilium Martagon* was very satisfactory, and so also were *L. pyrenaicum* and *L. pomponium*. I cannot understand why, apart from its rather strong scent, *L. pyrenaicum* should never come in for a word of praise. To my mind the greenish yellow flowers, with the rich red anthers, are very effective. *Lilium Brownii* served me in just the same way as recorded recently by a correspondent in THE GARDEN, i.e., it flowered well the first season after planting, but since then has disappeared. It may, perhaps, come up again this season, but I am very doubtful, as I searched for the bulbs, but could find no trace of them.

*Lilium tigrinum* and the variety *splendens* were remarkably successful, and made a brave show. What a much finer plant *splendens* is than the type! I might also say the same of *umbellatum grandiflorum*. The form I have under that name is much finer altogether than *umbellatum*. *L. candidum* was a failure. The growth reached about 12 inches high, then died off, and withered away. *L. auratum* and *L. speciosum* and varieties did fairly well, and *L. Hansonii* was very good. This is strange, as it had, perhaps, the worst position in the garden. It was planted in very heavy soil beneath some Poplars; nevertheless, it flowered well, and the bulbs were quite healthy when I took them up the other day to transplant in better soil. *Lilium superbum* grew well, but did not bloom. What distinct bulbs or rather rhizomes this Lily has! They are white, and the bulbs form at intervals along a thick rhizome, a fact which makes this Lily unsuitable for pot culture. I have recently planted a larger selection, comprising some of the more difficult sorts, such as *pardalinum*, *excelsum*, *szovitzianum*, *canadense*, *rubellum*, and *washingtonianum*.

All those I first mentioned were growing in the borders among herbaceous plants, and most of them received a good deal of sun. For these additional ones I have prepared a border which is partially shaded, and although I have not used any peat for those which are said to do best in this material, I have used a good deal of leaf-soil, sand, and ashes, so that on the whole the border may be said to be a great improvement upon that in which the other Lilies were grown. I hardly hope for much success with some of the most difficult ones, yet in the light of past experience I am sufficiently optimistic to expect that most of them will do well. I am now going to try *L. Grayi* and *L. Parryi*. Supposing some are not satisfactory, it will at least be interesting to try and find out how far Lilies will accommodate themselves to the conditions prevailing in an ordinary town garden.

A. P. H.

## THE BIRD'S-NEST FUNGUS

THE wise say there are compensations in every lot, probably that is why my garden, being particularly neglected and full of damp out-of-the-way corners, yields such a plentiful crop of fungi, in which I, making a special study of these humble plants, find some compensation for the deficiency in beauty and vigour of its rightful occupants.

Passing by the moulds that flourish on the decaying plants; the mildews that infest the Roses and *Chrysanthemums*; the rusts that discolour the Hollyhocks and Violets; the *Nectria* that studs the Currant twigs with scarlet spangle; and the *Agarics* that adorn the manure heaps, and spring up around the stumps of decaying trees, I desire to direct attention to one member only of this class, an interesting fungus that year by year never fails to make its appearance in a corner of the garden where some old cutting boxes have been left to rot. Its name is *Cyathus striatus*; it is one of the *Nidulariaceae*, and is known as the Bird's-nest Fungus, and the mature plant is certainly not unlike a miniature nest half full of tiny brownish grey eggs.

CYATHUS STRIATUS (BIRD'S-NEST FUNGUS).

A—Group of plants (natural size). B—Section of young plant. C—Interior of cup. D—Sporangia. E—Section of sporangium. F—Portion of same with basidia and spores (highly magnified).

While many fungi are rapid in growth and short lived, this little plant is slow both in growth and to decay. I generally notice them first in early autumn, and they last on into the spring. They appear in groups as little buff-coloured protuberances upon the rotten wood and soil in the old boxes, more or less round in shape, with a short stalk and rough outer skin. When nearly full grown, and about as big as a Hazel Nut, the top becomes flattened, with a slight rim, across which the now smooth skin is stretched. This soon splits, the skin shrivels and dries up, and discloses a cup-like cavity. Then the rim of the cup turns back, and the plant looks like a tiny erect vase with a smooth reflexed lip, slightly marked with radiating lines, and the interior half filled with rounded, shining, dark grey bodies. These are sporangia or spore-cases, and a section through a nearly mature cup shows that they are closely packed one upon another, to be somewhat triangular in shape, with a convex upper surface, and round depression on the under side, from which springs the short thick stalk by which they are attached to the base or side of cup. Further examination shows this little stalk to be composed of an infinite number of minute knobbed fibres, all twisted and entangled together in such a way that when pulled they will extend a considerable distance, and render the stalk highly elastic.

The use of this elasticity is seen when during heavy rains the spore-cases are washed out of the cups, the stalk spreads out into a long wide trail of fibres, and, by clinging to neighbouring objects and the soil, saves them from being washed away into uncongenial surroundings. A section (microscopic) of a sporangium shows an exterior dense fibrous rind, a zone of colourless parenchyma, and a central mass of closely-packed colourless spores.

At first sight there appears to be little identity of structure between a fungus like a Mushroom and this Cyathus; but they do agree, inasmuch as the spores are in both cases formed by abstriction, from the ends of specialised hyphæ branches or cells, known as basidia, only whereas in the Mushroom they are exposed upon the outer surface of the gills, and are quickly matured and freely dispersed, in Cyathus they are produced *within* a closed sporangium, which is again (at first) enclosed within the cup-like peridium.

Probably the length of time needed for their full development has something to do with these double provisions for their protection. As regards the ultimate fate of the little sporangia, I have never observed any fissure or pore indicating a rupture of the sporangium; they are probably washed out and dispersed a short distance by rain, when the spore-case gradually decays, or is eaten by creeping creatures of the soil, and the ripe spores are set free. But no doubt, like most fungi, the plant chiefly depends upon the growth of its mycelium for propagation. M. J. HUCKLE.

## GRADING AND PACKING FRUIT & VEGETABLES.

(Continued from page 63.)

With green vegetables, such as Cabbages, Savoy, Kale, and Brussels Sprouts, the principal point is to see that each sample is uniform and in the best condition, which is largely a question of care in gathering. For ordinary markets the two first named must be large and with solid hearts; for special sale and for sending direct to consumers a smaller size, but possessing all the other essential characters, is often preferable. Brussels

Sprouts should always be sorted into two grades, all the firmest and most compact into one, and the looser, rougher Sprouts into another; the increased price of the first will pay for this in the majority of cases. To Cauliflowers and Broccoli similar remarks apply; the most even and whitest heads constitute the first grade, the rougher and discoloured the second. As with Cabbages, large heads are required in general markets, but for the best sales moderate-sized perfect samples are the most satisfactory.

Other crops pay for attention in the same way. Rhubarb can be classed in two grades, the longest, straightest, and best coloured forming No. 1 bundles. Celery may be divided into two or three grades, the heaviest and most solid in bundles for salad, the others loose for soups. Asparagus, too, should be placed in two or three grades, according to the length, substance, and blanching; the smallest (Sprue) for soups; all the best in bundles of 25, 50, or 100, the last in larger numbers. Seakale can also be sorted, the best grown and whitest in bundles set upright in baskets.

Tomatoes demand the greatest care in sorting; two, three, and even four grades may be formed. The best in boxes or shallow baskets. The most even and brightest coloured fruits take the lead; there is a special demand for the largest handsome fruits in some markets, but the principal general sale is for good even-shaped, moderate-sized, uniform samples. Cucumbers are graded into two or three sizes; and Vegetable Marrows are also sorted, but in some places large specimens of the latter are most in demand, while in others a medium size is chiefly required.

**SALADING, LIKE LETTUCES AND ENDIVE,** can occasionally be separated into two grades, according to the solidity and blanching of their hearts, but as a rule a uniform sample of one value is preferable, to be regulated by the gathering.

The essential general rules in grading vegetables of all kinds are the following: (1) Exclude all immature, over-grown, coarse, or defective specimens from the leading grades. (2) Make each grade as uniform as possible. (3) Let freshness and fitness for use be the characteristics of all vegetables when consigned to market or consumers. To aid in all this only the best varieties obtainable should be grown, and growers should watch closely for every real improvement on old sorts.

### PACKING FOR SALE.

Wherever fruits or vegetables have to be transferred a distance by road or rail, the best culture and most careful grading may lose all their value through neglectful packing. That many of the defects in market consignments are either due to this or materially increased thereby the majority of salesmen can confirm, and the complaints on this score are as frequent as those regarding inattention to grading. In dealing with fruits the essentials for success are as follows: (1) Use only perfectly sound fruits. (2) Pack firmly, without crushing. (3) Use the best elastic odourless materials as packing. (4) Place all choice and ripe fruits in small quantities and shallow packages.

In the home trade baskets are much more extensively used than boxes, and the most common are round baskets without lids, of the bushel, half-bushel, or half-sieve types. They are strong and durable, but are objectionable for all the best fruits as, even with the most careful packing, the top layers are liable to be bruised, and under careless methods they are certain to be damaged. When Apples, Pears, Plums, Cherries, or Gooseberries are sent in such baskets a covering of paper, with straw or other material, is placed on the top and secured by cross pieces of Willow or Hazel, the points of which are forced through the sides of the basket below the rim. Flat baskets with lids are preferable but expensive, and the difficulty with all these is that they must be charged for or returned. In extensive dealings with market salesmen baskets are supplied at very little cost to the producer, but where it is desired to promote more direct communication between the grower and retailer or consumer some other method is preferable, or the producer must provide his own baskets. It would be helpful in many districts if a local industry

could be developed in cheap basket making; there are few places where suitable Willows could not be grown, and the basket making might be performed in the winter evenings. For useful information regarding Willows and Osiers suitable for the purpose named, see Leaflet No. 36.

(To be continued.)

## GARDENING OF THE WEEK.

### FRUIT GARDEN.

THE ORCHARD HOUSE—PEACHES AND NECTARINES.

**A**LLEXANDER, Hale's Early, and Waterloo Peaches and Nectarines Cardinal and Early Rivers' are forced in pots generally to obtain early fruits. These also save the permanent trees. The orchard house generally is not a forcing house, but one of the most useful houses in a garden. This has been amply proved during the past unfavourable season. It is much better to replot the trees every year, not necessarily giving them larger pots, but fresh soil. Any that have not been potted should now be top-dressed with good loam, lime rubble, and bone-meal, ramming well to make firm. If the pinching was carried out as advised last season, very little pruning will be required, except to remove any shoots to keep the trees in proper shape. Always cut back to a wood bud. The trees should be syriaged over with Quassia Extract, and arranged at the warmest end of the house. The varieties should include the best mid-season and late ones. Very little fire-heat will be required during the early stages of growth, and a temperature of 45° to 50° should not be exceeded until they come into flower, when 50° at night should be given, with a rise of 10° during bright days. Syringe the trees once or twice daily according to the weather, and keep up a constant circulation of air on all favourable occasions.

### PLUMS AND CHERRIES.

These trees can be started together, as both require the same treatment until the fruit is set, when a drier atmosphere must be given the Cherries. Neither will stand very high temperature, 40° at night, with a rise of 10° during day, being quite sufficient until the flowers open, when a little warmth in the pipes must be given. Allow plenty of air whenever the weather permits, and leave a little air on the top and side ventilators night and day. Fumigate the house before the flowers open if green or black fly appears.

### PEARS AND APRICOTS.

These require a drier atmosphere than Peaches and Nectarines, and also a lower temperature to set the blossoms satisfactorily. Go over the flowers daily with a camel-hair pencil, and also tap them two or three times daily.

### PEACHES AND NECTARINES OUTDOORS.

The mildness of the winter will bring wall trees into blossom, and every care should be taken to retard them. If the trees have not been untied, this should now be done, leaving them loose until just before the buds burst.

### APRICOTS OUTDOORS.

These trees also are in a very forward condition, and what little pruning is required should be done. The less winter pruning Apricots receive the better. Remove a few of the worst-placed spurs from old trees, and train in young wood to furnish vacant spaces; cut back weak shoots. Apricot trees are the first to need protection.

Impney Hall Gardens.

J. JORDAN.

### KITCHEN GARDEN.

#### BROCCOLI.

ATTENTION should now be turned to this important vegetable; the sorts on the market are bewildering and by far too numerous. Perhaps it would be of interest to give particulars of the selection made by my esteemed predecessor, who paid great attention to this crop, having tried a great number of varieties. To stand the vigour of our northern climate the hardiest and first to come

nto use after the Autumn Giant and Walcheren are over are Knight's Protecting and Backhouse's Winter White, followed a little later by Snow's Superb. For cutting early in the year Gordon's Niddrie Hybrid is found most suitable, followed by Leamington. Lauder's Goshen White and Alexandra make a good succession. To finish off this crop a good batch of Methven's June should be grown. This is perhaps the latest sort in existence, of exceptional hardness, and is a distinct acquisition. In very severe winters the plants may be lifted and heeled in in a sheltered position. This operation is, however, not often necessary, as the crop has stood as planted for the past three seasons here with good results. Seeds of this vegetable should be procured from the most reliable sources only.

ARTICHOKES.

The change in the weather permits several items in the kitchen garden to be taken in hand. Crops of the above that have been left in the ground may now be lifted. It is the general rule to grow this rather cumbersome plant on the same spot for the production of really first-class tubers. The ground should be well dug and heavily manured. The plot may be replanted at once after that operation has been carried out, planting the second-sized roots. The larger ones may be stored for use.

LEEKS.

If extra large or exhibition Leeks are required they should be sown now. The Lyon is a good sort for this work. Sow as advised for Onions in a temperature of 55°, reducing to 50° as the plants grow. The remains of last season's crops may now be lifted and laid in on the north side of a wall, thus allowing the ground to be dug or trenched.

GENERAL REMARKS.

If any of the autumn-planted Cabbage plants are broken or twisted by wind, the rows may be made up and a slight quantity of soil drawn to the plants. Cauliflowers wintering in the open should be protected by green branches of Spruce stuck thickly round the beds. Branches in frames ought to have plenty of air on all occasions, except during severe frost. Remove all dead leaves and stir the surface of the ground occasionally. Remove all dead leaves from plots containing Cabbages, Savoys, and Brussels Sprouts. This prevents their being blown about, and gives things a tidy appearance.

THOMAS HAY.

*Hopetoun House Gardens, N.B.*

FLOWER GARDEN.

LILY OF THE VALLEY.

ALTHOUGH autumn is the time usually recommended for the annual top-dressing of these beds it is by no means too late to do this now. The best border Lilies of the Valley I have ever seen were lightly top-dressed at the end of January with the clearings from fowl houses, which were kept well dusted with slaked lime. A good layer of rotten manure or a mixture of manure and leaf-soil will also, in most soils, give good results; if the soil is heavy the addition of some sharp sand will be beneficial.

In many places home-grown crowns are forced for supplies of cut flowers from now onwards, and in such places it is convenient to take up, as required, breadths of three year or older crowns. After sufficient of the best crowns are pricked out for forcing the remainder are graded into two or three sizes and replanted. Unless the old soil can be removed and a fresh bed made it will be advisable to replant these crowns in a fresh place, and for this purpose no place is better than a moist border at the foot of a shady wall. For the earliest supply of outdoor flowers a south aspect should be selected. A light, loamy soil, well worked and enriched with a good quantity of manure, will grow good Lilies. Before planting the soil must be made fairly firm. Any surplus crowns, no matter how weak, if planted in a moist spot in a frequented wood will, in a year or so, make a pleasing feature.

THE AMERICAN GARDEN.

The present will probably be found a convenient time to look over the plants and shrubs growing in

the American garden. Where the standard Rhododendrons are grafted on *R. ponticum* the stock frequently makes a thick growth around the stem; this should be kept cut away. Any that are not in a satisfactory condition will quickly improve if a moderate quantity of manure is forked in. Many soils are naturally suited for the growth of these shrubs, and beyond a little leaf-soil or peat at the time of planting will not require any addition. If the soil is of a chalky nature, or is very heavy, it will have to be removed and a suitable mixture provided. Where it can be obtained nothing is better than peat and leaf-soil in equal proportions, with sufficient gritty sand to keep it porous.

A. C. BARTLETT.

*Pencarrow Gardens, Bodmin.*

INDOOR GARDEN.

BOUVARDIAS.

Few flowering plants are more popular than these, as during the autumn and early winter months their delicately perfumed flowers appear always to be in demand. The finest flowers, perhaps, are obtained from one and two year old plants, and as for a few weeks now these will have been at rest, cut their shoots well back, leaving one, or not more than two, eyes of the previous season's growth. When new growths are sufficiently advanced, select a number of the strongest for propagation, and these will readily strike root when inserted in a sand bed in the propagating house or around the sides of 3-inch pots that have been previously well drained and filled with a suitable compost, cocoanut fibre, sand, and fine loam being suitable. Bottom-heat of 70° to 80° encourages them to emit roots early. The atmospheric temperature should be about 65°.

GREENHOUSE CALCEOLARIAS.

For making a show in the conservatory or greenhouse these are invaluable during May and the early part of June. Plants that are being grown for this purpose will by this time be ready for removal to their flowering pots, the size of which may be 7 inches to 8 inches, and the best position in which to place them afterwards is on a gravel or sand bed that is raised well up to the glass in a low roofed house or pit. For a few days after repotting withhold water from their roots, but keep the surroundings moist by syringing about the stages and amongst the pots. A light fumigation once a fortnight with XL All is advisable to prevent the appearance of aphid.

HIPPEASTRUMS.

While it may be necessary to repot some of the bulbs that require fresh soil or larger pots, it is unnecessary to repot all the stock annually. The compost in which they appear to grow and flower well is equal parts leaf-mould and fibrous loam, with about a sixth part of coarse sand, and a small proportion of old mortar rubble broken up moderately fine. Plunge those that are repotted in a slight bottom-heat, and avoid as far as possible the application of water to their roots, as syringing to maintain a moist atmosphere will be all that is required until growth is well advanced. The temperature previous to flowering should not range higher than 50° to 55°, giving air on all favourable occasions. Air also is required for plants that are growing, and the temperature should be raised from 55° to 60°; water with manure water.

*The Gardens, Tranby Croft, Hull.*

NOTES FROM SCOTLAND.

EDINBURGH INTERNATIONAL EXHIBITION IN 1905. THE decision of the Scottish Horticultural Association, at their annual meeting on the 12th inst., to give £60 towards the prize fund of the Royal Caledonian Horticultural Society for their international show in September, 1905, is likely to be much appreciated by the members of the Royal Caledonian, and is a token of the good feeling which has for some time existed between the two societies. The Lord Provost's Committee

of Edinburgh Town Council has also agreed to recommend a grant of £50 from the Corporation funds for the same object.

TREE PLANTING IN GEORGE STREET, EDINBURGH.

For some time proposals to plant trees in George Street, Edinburgh, have been under discussion, and in order to make a practical experiment the City Parks Committee has caused six trees to be planted in the street in the division from Hanover Street to Dowell's Rooms. Should the experiment meet with general approval the planting will be extended, and there can be little doubt that a great improvement in the aspect of this fine street would be the outcome of tree planting all along its length.

FORESTRY IN SCOTLAND.

An important step in the promotion of scientific forestry in Scotland is likely to be taken shortly by the institution of a degree in forestry by the University of Edinburgh, in conjunction with the Scottish agricultural colleges, which has made great strides in practical teaching of late years. It is proposed that the university shall undertake the central work of forestry teaching, but that the provincial work shall be undertaken by the agricultural colleges. The national importance of the promotion of forestry in Scotland can hardly be over-estimated, and it is confidently expected that the establishment of a degree will be of much benefit.

NURSERY GARDENS.

MESSRS. HENRY CANNELL AND SONS, SWANLEY, KENT.

AMONG several flowers the improvement of which Mr. Henry Cannell, sen., is closely identified with, those we shall now concern ourselves with are zonal Pelargoniums and Chinese Primulas, both of which are valuable winter-flowering plants; indeed, they are indispensable. Although

ZONAL PELARGONIUMS

have been in flower for weeks, they are not yet over; in fact, they still make a very bright display in some of the houses at Swanley, a fact that impresses one with their value both as decorative plants and for cut bloom, for Mr. Cannell informed us that there has latterly been a good demand for zonal Pelargoniums as cut flowers. If the petals are gummed slightly the blooms will last in water for a long time. There are many lovely varieties among these plants to-day, a great improvement in every way so far as size and colour are concerned, and none who value brilliant colour in their greenhouses during the dullest months of the year can well afford to ignore them. Take, for instance, six new varieties raised and distributed by Messrs. Cannell in 1903: Duke of Connaught, with large and beautiful magenta flowers, with a pure white eye; Countess of Dudley, a fancy sort, orange-scarlet, with large white centre, the trusses of bloom of great size; Duke of Bedford, rich red, with white eye; Prince of Orange, orange-scarlet; The Rev. H. A. Hall, glowing red-crimson; and The Ghost, with large pearly white blooms of fine form.

Among the older varieties, too, there are many of great merit; those who prefer the semi-double ones (and they have the advantage of lasting longer and being more useful for decorative purposes than the singles) have a large selection to choose from. Some of those Messrs. Cannell consider to be the best are given—Mme. Fournier Sarlovez, bluish pink, enormous trusses of bloom; Grenade Poitvine, light scarlet, with large pips; Jeao Viand, very large, soft rose-pink; Le Colosse, clear red; Gustave Erich, rich clear scarlet; Mme. Charlotte, a variety of dwarf habit, salmon. Of scarlet and orange-scarlet semi-double varieties the best are M. Alf. Erckeiner, a beautiful soft orange; Raspail Improved, a most valuable deep scarlet Pelargonium. Of cerise scarlet, Transvaal and Dr. Verneuil are most to be recommended; while M. Anatole Roseleur, rose-pink; Mme. Grillott, soft

rose; and Tendresse, soft pink, are very beautiful. Of deep crimson varieties, Double Jacoby is the best; Colonel de Villebois-Mareuil is a fine purple; Miss G. Ashworth and White Abbey are the best whites; Madeleine Lemaire and Gustave Lanson and Circe are good salmon-coloured sorts; while Olive Schreiner and Mme. de St. Vallières are whites with Picotee edge.

Among the single varieties are many of great merit, but we can only mention a few, *e.g.*, Princess of Wales, rosy cerise; Duke of Marlborough, intense crimson, tinted purple with white eye; General French, soft scarlet; Mr. T. E. Green, orange; Lord Curzon, rich magenta; Lord Roberts, purple; Countess of Hopetoun, bright salmon, with pure white margins; Mrs. George Cadbury, salmon; Mrs. Charles Pearson, orange-salmon; Barbara Hope, salmon-pink; Sir Wilfred Laurier is white and vivid magenta; Mr. Winston Churchill is magenta-pink, with large well defined white centre; Mark Twain has flowers whose ground colour is almost white, and flaked with carmine; Mrs. Brown Potter is a clear bright pink; Mrs. Williams, rose pink; Snowstorm, Mary Beton, and Mary E. Wilkins, pure white.

Such are a few of the best zonal Pelargoniums of to-day, and it is not too much to say that their superiority over those of twenty or thirty years ago is largely due to the labours of Mr. Henry Cannell.

#### PRIMULAS.

Primulas are slowly yet surely undergoing a great change, and probably it will not be many years before the varieties of *Primula sinensis*, so largely grown at the present time, will be replaced by plants with flowers of equally rich and varied colouring, and far more attractive inflorescence and habit of growth. At any rate, Mr. Cannell, who has been engaged in producing new varieties of Primulas for many years, seems to think this is the case. And it cannot be denied that the varieties of *Primula sinensis*, although almost perfect as regards size, form, and colour of bloom, are too compact, the inflorescences too dumpy even to be called beautiful. Already the hybridist has done much to overcome this fault by intercrossing *Primula stellata*—a plant originally with small, somewhat star-shaped blooms and graceful pyramidal habit of flowering—with the Chinese varieties. So far, the results appear chiefly to be apparent in finer forms of *Primula stellata*, and very beautiful they are; the flowers are larger, of better form, fresh colours have been introduced, while the attractive pyramidal inflorescence remains. Now these improved varieties of *P. stellata* are being crossed with the best forms of *P. sinensis*, and in Messrs. Cannell's Swanley nursery we saw the latest results. The blooms one might almost call perfect; they are so elegant in form, the outline of each petal is so true. Although we do not wish to see artificial symmetry in all garden flowers, there is no doubt that some are better for it, and among them is the Primula.

There are numerous new sorts in Messrs. Cannell's houses, all the result of crosses between the best forms of *P. stellata* and *P. sinensis*; most of them are yet unnamed, so that we cannot describe them individually, but it is not too much to say that they have come to stay. The "dumpy" habit of the Chinese Primula has to a great extent disappeared, to give way to an altogether more graceful plant with branching flower-stems. When Mr. Cannell showed us, side by side, a plant of the old *P. stellata* with small, unattractive, pale purple flowers, and the latest product of the hybridist's art with large, symmetrical blooms and firm, compact leaves, the enormous improvements that have been made were apparent. Messrs. Cannell have several very beautiful white Primulas; the white is quite pure, and, when this is the case, there is none more beautiful. If a so-called white Primula is not white, then its claim to admiration is gone. Among novelties we may mention Cannell's Red Rover (*stellata* type), with clear carmine-red flowers and pyramidal habit; Cannell's Triumph, also of the *stellata* type, rich magenta in colour; and Cannell's White Spray (*stellata*), a pure white, and the flowers are very freely produced. There are, of course, many other varieties of great merit in

Messrs. Cannell's collection; in fact, they are so numerous that we refrain from attempting to enumerate them.

#### TWO VALUABLE WINTER-FLOWERING PLANTS.

We have rarely seen *Coleus thyrsoides* and *Moschosma riparium* more finely grown than in the Swanley nursery. Both these plants have been discussed a good deal lately, and there is no doubt that when well grown they are most valuable during December, January, and even February. The rich blue spicate racemes of the *Coleus* and the white flowers of the *Moschosma* were very striking together; both these are plants that unless well grown are sure to cause disappointment. But, on the other hand, master their culture, which is not difficult to do, and you will be delighted with the results.

## THE FLOWER GARDEN.

### THE AGRIMONIAS.

ALTHOUGH over fifty different species have been described by various authors as belonging to this genus, it may be safely assumed that only a quarter of that number are entitled to specific rank. The distinctive differences between the recognised species are very small, consisting mainly of various degrees of hairiness of the stems and foliage, size attained by the plant, and lax or crowded flower-spike, as well as the size of the fruit and length of the hooked spines with which it is furnished. A genus of hardy herbaceous perennials, its chief home is in the northern temperate regions of Europe, Asia, and America, but it is also represented in South America. They are erect-growing plants, with interruptedly pinnate leaves and usually long spikes of yellow flowers with notched petals, mostly found on roadsides, borders of fields, and in waste places. While they cannot be included among the more showy plants for decorative purposes, they are interesting enough for the mixed or shrubby borders and the wild garden, where they require no special attention. The following is a selection of the most distinct species, all of which are in cultivation, but chiefly in botanic gardens:—

*A. agrimonoides*.—The three-leaved Agrimony is sometimes known by the generic name of *Aremonia*. It is the most distinct species belonging to the genus, being a low-growing dwarf plant, the root leaves of which are pinnate, with unequal leaflets, while the stem leaves are ternate, on short stalks. The flowers are yellow, in leafy panicles somewhat resembling a *Waldsteinia* in appearance, being the largest produced by any of the members of this genus. It is a native of Eastern Europe, inhabiting rough wooded hills from the Tyrol to Macedonia.

*A. Eupatoria*.—The common Agrimony is a well-known inhabitant of this country, frequently met with by the waysides and borders of woods. An erect-growing, hairy perennial, having the characteristic pinnate leaves with unequal leaflets of oval form, coarsely serrated. The flowers are yellow, borne on long spikes, and are succeeded by small burr-like fruits. Having a wide distribution, this plant is found in North America and Asia as well as in Europe.

*A. leucantha* is a plant of doubtful origin, somewhat resembling *A. repens*, of which it may be a weak form, with shorter spines on the fruits.

*A. odorata*.—The sweet-scented Agrimony is also a native of this country, but is not so frequently met with as the common one, as it

is a much rarer plant. It is of a more robust habit, reaching a height of 3 feet to 4 feet, and is much more hairy, with branching spikes of larger yellow flowers. These are closely set on the long spikes and produced in June, followed by larger fruits armed with longer spines. It is generally found growing in thickets and shady places distributed over the greater part of Europe.

*A. parviflora*.—A tall-growing, erect plant, reaching a height of 4 feet to 5 feet, with interruptedly pinnate leaves, the leaflets of which are narrow and often linear, 2 inches to 3 inches long, with serrate margins. The flowers are small and pale yellow in colour, borne on long spikes in July and August. A native of North America, where it is found in woods and dry meadows.

*A. repens*.—The specific name given to this plant does not refer to the stems, which are erect, freely branching halfway up into several long spikes of good-sized yellow flowers, closely packed together. Like most of the other species, this is very hairy, with narrowly ovate leaflets. A native of Eastern Europe and Asia Minor, it is also found in Spain. Other species are *A. incisa*, from North America, with larger flowers than in *A. parviflora*, on a long, lax spike, and with shorter leaflets. *A. nepalensis* has yellow flowers on slender spikes, on erect stems, with ovate leaflets. *A. pilosa* is found in Northern Europe, extending across Northern Asia to Japan. It is similar to *A. Eupatoria*, but is not so hairy, and is often found growing near water. *A. sororia* is a Caucasian plant, with a long, lax inflorescence of small yellow flowers on weak stems.

W. IRVING.

## MISCELLANEOUS.

### THE HARDINESS OF PLANTS.

THE remark that such a plant is hardy, or only half-hardy, or is tender, is one that is often heard, but a proper idea of what is actually meant is not so readily conveyed. The hardness of a plant, that is to say, its ability to withstand the various changes of our climate without injury, and also at the same time to look healthy and grow freely depends upon, firstly, the extent of its adaptability to our climate; secondly, constitutional vigour; and, thirdly, upon its season of growth. For present purposes the United Kingdom may be divided into three parts according to the climatic conditions and their influence on plant growth. The first and warmest part, therefore the most favourable one, is found to the south-west and west of a line drawn from Southampton to Bristol, and then north to Flint, passing over the Irish Sea to Dumfries, and then north-west to Ayr. The whole of Ireland, with the exception of the north-eastern corner, may be included. The second and intermediate part lies to the east of a line drawn from Southampton to Bristol, and then north-east to the Wash. Starting from the Bristol-Wash line, a line nearly due north through Birmingham to Carlisle, would also belong to this second part. The north-east corner of Ireland may be included. The remainder of the country would belong to the coldest division. This classification, however, must not be considered a hard and fast one, as even in the colder localities certain places are to be found where plants will thrive almost as well as they do in the warmer division.

It has been found that half-hardy plants sent from a warm part to a colder one invariably suffer badly, even if they are not killed outright, though the same plants do much better if they have been growing in an intermediate climate. A proof of this is seen by the plants that are sent from England to America annually. Two of these, *Andromeda floribunda* and *Kalmia latifolia*, are natives of the more southern parts of the United States, and

they are found to thrive better in New York and some of the Northern States when sent out from England than if home-grown plants are used. *Rhododendron catawbiense*, again, is a native of the mountainous parts from Virginia to Georgia, and will not thrive at all in most parts of the Northern States, but hybrid *Rhododendrons*, chiefly *catawbiense* strain, do well almost anywhere in the States. *Andromeda japonica* and *Ilex crenata* are natives of Japan which do better in America when imported from England than if they are obtained direct from Japan or grown as nursery stock in the warmer parts of the States.

The season of growth is an important factor in determining the hardiness of a plant. Thus, for instance, *Tilia mandshurica*, *Rhododendron dahuricum*, and *Cercidiphyllum japonicum* are examples of plants that begin to grow too early in the spring, and in most places are crippled by frost as soon as they have pushed forth a few leaves. All three in their native habitats pass through winters quite as severe as an ordinary English one, but their time of starting into growth happens to coincide with the worst phases of an English spring, when a few bright days are followed by sharp frosts. It is not only the spring frosts that cripple plants, but early autumn frosts also cause injury to many otherwise hardy subjects which grow late in the season by cutting their growths before they have properly ripened. These are chiefly coniferous subjects, of which *Abies*, *pectinata* (the Silver Fir), *A. cephalonica*, *Sequoia sempervirens*, and *Cunninghamia sinensis* are good examples. These grow both early and late, and are bound to get cut by frost either in spring or autumn until they reach a height of 10 feet and upwards, when they are above the frost line, and usually escape without further serious injury. The difficulty, however, is to get them up to that height, as the leaders are cut annually and the plants spread laterally without going upwards.

A sheltered spot is usually recommended as the proper situation to plant tender things, but I am rather doubtful if this advice is always correct. Here we used to plant *Escallonias*, *Laurustinus*, *Arbutus*, and *Cupressus macrocarpa lutea* in a sheltered spot, but they somehow got badly injured in most seasons. Now we grow them on a bare hillside, facing nearly due east, and though they grow less rapidly they seldom get injured by frost. With many half-tender plants, however, that get frozen, much depends on how soon the sun catches them in the morning, as if they are so shielded from the sun's rays that they thaw out gradually they will withstand much severer frosts without injury than if they were exposed to the sun and suddenly thawed.

It is my firm belief that many half-hardy plants could be made much hardier if seeds were used as a means of reproduction instead of cuttings, &c. Many of them, however, will not ripen seeds in this country, but if they happen to do so, as they sometimes will in a favourable summer, then seeds should be used as a means of propagating them, and if persisted in for a few generations, a hardier race more suited to withstand our changeable climate would be the result.

Bagshot.

J. C.

**CORRESPONDENCE.**

(The Editor is not responsible for the opinions expressed by correspondents.)

**THE GRAPE FRUIT.**

[TO THE EDITOR OF "THE GARDEN."]

SIR,—In your issue for December 26, 1903, in continuation of the very interesting article on "Gardens of Jamaica," reference is made to the Grape Fruit, and it is said: "It is of about the size of what in the East Indies is called the Pummelo, which is, however, of the Shaddock species." The Grape Fruit is now grown quite extensively in Florida, and is increasing in favour in our markets. American authorities call Shaddocks and Pomeles (our form of spelling), or

Grape Fruit, varieties of the Malayan *Citrus decumana*, but we reserve the name Shaddock for the large, rather Pear-shaped variety, while the Grape Fruit, Pomelo, or Forbidden Fruit, is round and smooth, like an overgrown, pale-coloured Orange. It is thin-skinned for its size, and very juicy, but the tough skin makes it ship well. The inner rind and "rag," or skin separating the pulp, is very tough and bitter, and this bitter sub-flavour often extends to the pulp, but one soon acquires a taste for it. Americans think the Grape Fruit a tonic against malaria, and it is a favourite fruit course at breakfast. To serve the fruit cut across transversely, cut out the tough skin in the centre with sharp-pointed scissors, and loosen the sections from the skin at the sides with a sharp knife so that the appearance of the pulp is not disturbed. The half sections are served on small plates, and the pulp eaten from the skin with a spoon. If desired a little maraschino is poured over the pulp, and a few preserved Cherries are put in the centre whence the skin has been removed. This is a delicious fillip to the appetite, and is often served as a first course at the ladies' luncheons so popular here. The pulp of Grape Fruit scraped from the skin and then returned to the rind, with the addition of a tablespoonful of sherry, is very refreshing and appetising in an invalid. The flavour of the Grape Fruit blends delightfully with red Raspberries, and a most agreeable dessert is made by scraping the pulp and skin from the rind, after cutting the Grape Fruit through as previously described, filling the rind with red Raspberries and then pouring over them the pulp and juice of the other fruit, with a dusting of powdered sugar. In Florida the Grape Fruit is wonderfully productive, a crop of sixteen barrels being reported from a tree twenty-five years old. There are now several fixed varieties of special merit, Mays' Pomelo, which is said to show some admixture of Orange, being considered among the best. Descriptions of warm weather desserts and tropical fruits seem hardly appropriate to our locality just now, as on two days during the past week (the 5th and 6th inst.) the temperature went down to 18° and 22° below zero respectively. Fortunately, there is a heavy blanket of snow, which lessens anxiety for the garden, but I think if my pet plant of *Stokesia cyanea* survives this winter it may justly be described as ironclad.

EMILY TAPLIN ROYLE.  
Maywood, N.J.

[*Citrus decumana* is known by several names: Pomelo, Pumelo, Pummelo, and Pomalo, but Pomelo is the form commonly adopted.—Ed.]

**APPLE BISMARCK.**

[TO THE EDITOR OF "THE GARDEN."]

SIR,—From this variety seems to be evolved the nearest approach to the perfect Apple, judging by the opinion and experience of "D. K.," County Cavan (page 14). To show how diverse is the experience of growers concerning individual sorts, I would point out that the Bismarck Apple is so poor here that I have just headed down a twelve year old garden bush preparatory to re-grafting in spring. The

extent of its crop during that period fell very short of many other cooking varieties cultivated, and therefore I am not keeping even one tree. Though my experience is so different to "D. K.'s," I can assure him that Bismarck, planted as orchard standards, at the Bromham Fruit Farm, Chippenham, now so famous for Chrysanthemums, is the most profitable and best Apple on the red soil of that favoured district. It crops heavily, colours grandly, keeps and sells well; but in spite of all these excellent attributes I am not sure that it combines all that is needed to constitute the perfect Apple. When success and failure become so pronounced an Apple can scarcely be regarded as perfect, though I would certainly not condemn a variety because in a few instances it did not crop well.

Wills.

W. S.

**ORCHIDS.**

**VANDA CÆRULEA.**

WE grow *Vanda cœrulea* in teak baskets, suspended near the ventilators, from the roof of a large stove. All are entirely removed from the baskets in the middle of March, dead roots are cut clean away, and the plants thoroughly cleansed with tepid water. They are replaced, and the baskets are filled with fresh-picked sphagnum moss and pieces of charcoal about the size of a Walnut. The compost is made as firm as possible, and the surface is finished off with living heads of sphagnum moss. Water is given with great care, and only the surface is lightly sprayed with a fine rose so as gently to encourage root action, which begins generally at the end of March or early April here. When

VANDA CÆRULEA IN BROUGHAM HALL GARDENS.

the plants are in full growth and during the summer months abundance of water is given, and the baskets are frequently dipped. By the end of August the plants are not rooting so freely, and the flower spikes begin to appear. At this sign we commence to lessen gradually the supply of water, so as to have the sphagnum practically dry by the end of October. We endeavour to rest the plants as much as possible through the winter months. If the leaves show any signs of shrivelling, we slightly damp with a syringe the outside of the basket and surface of moss, but avoid saturating the whole compost.

Briefly stated, such is the practice carried out here in the cultivation of this lovely Orchid.

A. TAYLOR.

*The Gardens, Brougham, Penwith.*

### THE WEEK'S WORK.

#### REJUVENATING CYPRIPEDIUMS.

THOSE blooms that have been open for some weeks should be cut, and any plants in need of repotting or dividing should be taken in hand at once. To obtain the best results it is most essential that they should be divided from time to time. It is practically impossible to give fresh material to the inside roots of a mass. If the plant is potted the outer growth and roots will benefit, but the centre is in a degree starved. I do not wish to condemn the desirability of growing specimens, but rather the practice of allowing a specimen to remain a specimen.

I prefer growing them until the centre of the plant shows signs of deteriorating, and then pull it to pieces. If some are treated this way each year the stock of specimens can be kept in a more vigorous state. Perhaps no two varieties have been subjected to such severe propagation as *C. insigne* Sanderae and *C. i.* Harefield Hall var., yet they produce flowers of the finest quality, and I have always found that a plant that has adequate room to develop each growth is the one that gives the best results. A good compost for *C. insigne*, *C. Argus*, and other winter-blooming *Cypripediums* consists of one-half good fibrous loam, one-fourth good peat, and one-fourth good leaf-soil, well mixed together, with a fair sprinkling of coarse sand and small broken crocks to ensure porosity. A thorough drainage of chopped rhizomes should be afforded to enable the plants to have copious supplies of water during the growing season.

#### DIVIDING THE PLANTS.

In dividing great care should be taken to preserve as many roots as possible. After working out as much of the old compost as possible, wash the roots until all the old material is gone. It will then be found much easier to see the most suitable places for dividing. All damaged roots should be cut where broken. When restaging the divided plants should be placed by themselves, to allow of rather closer attention being given them for a time. They will require but little water at the root for some time, but the compost should on no account be allowed to remain dry. Keep the atmosphere moist. The potted-on plants should also be watered with discretion till the roots have taken a good hold of the new compost. These also derive benefit from atmospheric moisture. Increase overhead spraying as the days lengthen. The intermediate house temperature is very suitable for their requirements.

#### AMATEURS

wishing to make a start in Orchid growing could not do better than take up *C. insigne*, *C. spicerianum*, *C. Argus*, and some of their hybrids and varieties. I have many times seen these winter-flowering Orchids admirably grown in an ordinary greenhouse; they last in flower many weeks, are of very easy culture, and there are enough distinct forms to make a most interesting collection. Many of them can be purchased cheaply.

*Gulton Park Gardens, Reigate.*

## BOOKS.

### The Culture of Vegetables and Flowers from Seeds and Roots.

—No book upon the culture of vegetables contains simpler directions for carrying out details which means ultimate success than this publication of Messrs. Sutton and Sons of Reading. It is well printed, well bound, and illustrations are inserted where deemed advisable. The first portion of the book is devoted to vegetables, and opens with the *Globe Artichoke*, followed by the *Jerusalem Artichoke* and *Asparagus*, and in the article on *Asparagus* occur some excellent remarks about the white *versus* the green, though the authors "on the point of taste . . . say nothing; and it is a mere matter of management whether the sticks are blanched to the very top or allowed to become green for some few inches. . . . There is an interesting point in connexion with the production of green *Asparagus*, and it is that if wintry weather prevails when the heads are rising (as, unfortunately, is often the case), the tender green tops may be melted by frost and become worthless, or may be rendered so tough as to place the quality below that of blanched *Asparagus*; for the blanching is also a protective process, and quickly-grown white *Asparagus* is often more tender and tasty than that which is green, but has been grown slowly. As the season advances, and the heads rise rapidly, the green *Asparagus* acquires its proper flavour and tenderness, and thus practical considerations should more or less influence final decisions on matters of taste. The business of the cultivator is to produce the kind of growth that is required, whether white or green, or of a quality intermediate between the two. This is easily done, making allowance for conditions."

There is a most useful chapter upon "Herbs," page 61. The following paragraph shows the praiseworthy nature of the proffered advice: "In the smallest gardens *Mint*, *Parsley*, *Sage*, and both common and *Lemon Thyme* must find a place. In gardens which have any pretension to supply the needs of a luxurious table there should be added *Basil*, *Chives*, *Pot* and *Sweet Marjoram*, *Summer* and *Winter Savoury*, *Sorrel*, *Tarragon*, and others that may be in especial favour."

We looked with interest to the chapter upon the *Potato*, knowing the great work this firm has accomplished in raising varieties that, if not impervious to disease, are less liable to attack than other sorts. The following remarks are truthful, and show the right spirit to regard the sensational developments in disease-resisting varieties that are said to have lately taken place: "Since the introduction of *Sutton's Magnum Bonum Potato* there is a disposition to believe in 'disease-proof Potatoes.' There is no such thing absolutely, and perhaps there never will be, any more than there is a disease-proof wheat, or dog, or horse, or man. But some varieties of *Potato* are known to be more susceptible to the ravages of disease than others, and it has been one of our aims to secure seedlings which combine the highest cropping and table qualities with the least tendency to succumb in seasons when conditions favour the spread of the fungus. . . . To sum up this subject, then, we say that disease may be avoided in the early crops by cultivating sorts which may be lifted before the plague generally appears; and on soils which will not produce an early crop, only such varieties should be grown for the main crops as have been proved to be most capable of standing uninjured until late in the season. Let there be a dry, warm bed, sufficient food, the fullest exposure to the life-giving powers of light, and conditions favourable to early ripening." An invaluable guide is given, beginning at page 146, on "A Year's Work in the Vegetable Garden," and articles upon "The Rotation of Crops," "The Chemistry of Garden Crops," "The Culture of Flowers for Seeds," "A Year's Work in the Flower Garden," "The Making of Lawns and Tennis Grounds," and "The Insect and Fungoid Pests that Trouble the Gardener." The book is thoroughly practical, and is written in a straightforward way. There is no attempt at "fine" writing;.

### A Flora of the Island of Jersey.†—

This is an interesting guide to the flower life of sunny Jersey, and reveals that the study of the flora has been conscientiously undertaken. In his lengthy introduction the author writes: "At the present time Jersey presents six different kinds of station, and each, to a very large extent, has its own flora. (a) Sandy beaches, sand-dunes, and sandy fields near the sea; (b) granite sea cliffs; (c) salt marshes—these have almost entirely disappeared; (d) rough moorland and hillsides; (e) ordinary, cultivated, flat table-land; (f) sheltered, moist valleys and low-lying meadows. It is worth noticing that most of the plants of South and West Europe which form the most interesting feature of the Jersey flora affect station a." The arrangement of the flora is based upon Engler's "Die Natürlichen Pflanzenfamilien," and, happily, the author publishes an arrangement of the genera of British plants in accordance with Engler's system. It is severely technical, and presented in a way that can only appeal to the ardent botanist, which is perhaps as well. Such books have little interest to the ordinary tourist, as the arrangement and scanty descriptions are to him almost unintelligible. A meteorological table embracing eight years is published, and the following remarks about the climate are interesting. The author writes: "The climate of Jersey is mild and equable. Summer merges almost imperceptibly into autumn, and autumn into winter, and cold weather is rare before the new year. Severe frosts are very unusual, and snow seldom lies long upon the ground. The coldest months are January and February, the warmest July and August. The number of hours of bright sunshine is large (1,930 on an average of fifteen years; *Rev. H. W. Yorke, Quarterly Journal of Meteorological Society*, July, 1899), but the air is always laden with moisture, and often feels more chilly than the thermometer readings would seem to indicate."

**A Book About Shrubs.‡—**A capital little book about shrubs, with sensible advice upon selections of the best kinds, arrangement of the shrubbery, propagation, and other aspects of a subject which is becoming of increasing importance in English gardens. There are several helpful illustrations.

## AMERICAN NOTES.

### A WINTER BOUQUET.

AS we are far from any florist we must, in winter, depend upon our own resources for flowers and plants with which to decorate the house. A few days ago I wanted some evergreens to make wreaths and garlands, and to fill vases and jars, in order to give the house a more festive appearance than usual; so I took a large basket and a pair of shears and sallied out to see what I could find in the garden and shrubberies. I went first to the rockery, and looked at the clumps of

#### GALAX APHYLLA,

the plant from North Carolina that furnishes occupation in early winter for so many of the mountain folk, who gather the leaves to send to all our largest cities for holiday decorations. But my clumps are too small and too newly-established. They could only spare me a few leaves here and there. There are two varieties of *Galax* leaves, the green and the bronze. I do not know what makes the difference in colour. Mine belong to the green-leaved sort; but the bronze is the prettier, and makes very effective wreaths. Leaving the rockery, I next followed the path that leads to the Oaks until I came to a large clump of the common

JAPANESE EUONYMUS

full of well-berried shoots. The glossy, neatly scalloped, dark green leaves and the bright berries presented just the combination I was looking for, and I paused to wonder why this Euonymus has not found more favour with the dealers in decorative greens. It makes charming wreaths, and remains fresh a long time. It is true that this Euonymus is not hardy in our colder States, but it could be imported from the South as well as the Galax. My bushes are not very large, but there are many of them; so I took a liberal contribution, and passed on a few steps to halt again in front of our prime favourite, the

JAPANESE MAHONIA,

which does much better here than the American species. It is a great spreading bush 6 feet in height. Its lower branches rest upon the ground, and its large spiny leaves are green and glossy. Its shoots are terminated by many tassels of flower-buds, which hang with a graceful droop, giving promise that they are seldom able to perform, of abundant blossoming in early spring. Some of these shoots were added to the basket. The bright yellow wood of this Mahonia is very tough, and it was prickly work to cut them, as the sharp spines on the leaves pierce like needles; but I knew how effective these little branches would be in vases and jars, so I persevered until I had secured a good many of them. The foliage of this Mahonia is the best substitute we have for that of the Holly, though the leaves are much larger than Holly leaves. The American Holly does not find the soil here very congenial, and its growth is exceedingly slow. After reading the accounts lately published in THE GARDEN of the beautiful Hollies so much grown in England, we are anxious to experiment with some of them, and hope to make a small planting of them next spring; but very few of the broad-leaved evergreens used in England do well with us. Passing on into the wild garden, the next halt is made in front of

SIEBOLD'S EUONYMUS,

a large bush whose foliage is almost evergreen. It is at least persistent, though it has a drooping and wilted appearance in the winter. But the little orange and red berries glow like fire coals, and are thickly clustered all over the bush. These will be pretty to mingle with Box and other evergreens, and to decorate the long sprays of Vinca minor that we use for garlands. The evergreen Thorns add some sprigs and branches, but I look in vain for fruit. Some long sprays of evergreen Honeysuckle are next secured, and I search the Bush Honeysuckles for berries, but find them too much shrivelled, such of them as have been spared by the birds. Ivy is rejected, as too closely associated with funerals. The Yucca bank seems more promising, for I know by experience to what use I can put the sheaths of sword-shaped leaves of Yucca filamentosa, Y. angustifolia, Y. flaccida, and some other kinds. They mingle well with other evergreens in large jars, or can be used to give foliage to plumes of Pampas Grass.

This almost exhausts our list of broad-leaved evergreens. Even the humble herb bed is not to be overlooked in this niggardly season. Two or three good bunches of Thyme, Sweet Marjoram, and Hyssop are placed in the fast filling basket, to lend their aroma to our winter bouquet, and in a sheltered corner I find some clumps of Lemon Balm looking almost as fresh as it did in May. My next thought is of bright-berried plants. By the gate I find a group of

THUNBERG'S BARBERRY,

with abundant scarlet fruit, and scant shrivelled foliage of dull salmon-pink. This is just the thing to give a few touches of colour to our decorations, so a liberal quantity of it is cut.

Another valuable find is the Bitter Sweet upon the old Cedar trees of Cedar Ledge. I gather all that I can reach, half reluctant to deprive the Cedars of such a pretty ornament. Rose hips are now too much shrivelled, though I can find a few here and there still plump enough to serve my turn. The odd mauve-coloured berries of the Callicarpa

are dainty with their metallic lustre, and can be used with bunches of Grasses and in other ways.

Now I must look to the Pines and other narrow-leaved evergreens to complete my collection. An oddly-contorted branch of

PINUS MASSONIANA

delights my eye, as I picture it the sole occupant of an ancient dark blue jar of some odd Chinese ware, which is one of my greatest treasures.

The Austrian Pine is a fine cheerful shade of green, much better than our native White Pine, which looks unusually rusty. So I cut and snip here and there with a lavish hand, for the Pine is large, and will not miss its contribution to our festivities.

I pass by Retinosporas, Arbor-Vitæ, Cephalotaxus, and other evergreens with only a critical glance, for our hard winters dull and brown them past usefulness. Then I come to my favourite

DOUGLAS SPRUCE

to prune it a little with a tender hand. I love to feel its soft yielding foliage, but the young tree is such a fine symmetrical shape that I am afraid of spoiling it by a careless use of the shears. Now, although the White Cedars and some Spruces and Firs look very desirable, my load is as heavy as I care to carry, so I go back to the house well pleased with my gathering. With the few Palms, Ferns, and potted plants that we have, including a fine Araucaria, I have material enough to make the hall and living rooms bright for many days.

DANSKE DANDRIDGE.

Shepherdstown, Jefferson County,  
West Virginia, U.S.A.

OBITUARY.

MR. HUGH FRASER.

By the death of Mr. Hugh Fraser, nurseryman, Leith, which took place on the 13th inst., at the age of seventy-one, as already announced in THE GARDEN, Scottish horticulture loses one who was widely known and deeply respected. All his career was associated with the nursery trade, but his duties necessarily brought him in contact with many private gardeners and others, by whom he was greatly esteemed. All who knew him regret his loss. Mr. Fraser was born in 1833, in the Leith Walk Nurseries, then belonging to the firm of Eagle and Henderson, for whom his father was manager. Naturally, with the tastes he showed at an early period of his life, Mr. Fraser elected to follow his father's vocation, and began his career in the employment of Messrs. Purdie and Merlees, who had at that time a nursery called the Stanwell Nurseries, the offices and greenhouses being on the site now occupied by the Bonnington Road School. Afterwards the business was taken over by the late Bailie Methven, with whom Mr. Fraser remained. The development of this business, now so well known as that of Messrs. T. Methven and Sons, one of the leading firms of its kind in Scotland, afforded a good opportunity for the energy and knowledge of Mr. Fraser, who eventually rose to become traveller and manager. This position he retained with the full confidence of his employers and of their clients until a few years ago, when ill-health caused him to give it up. He took a great interest in the formation of the now flourishing Scottish Horticultural Association, and was long a member of its committee, and for some time occupied the position of president. The papers he contributed to its meetings were much valued. Mr. Fraser was also a Fellow of the Botanical Society of Edinburgh, and an honorary member of the Edinburgh Field Naturalists' Society. A lover of literature of all kinds, it is not surprising that Mr. Fraser utilised the knowledge of his profession in the preparation of a valuable little work entitled "Handy Book of Ornamental Conifers, Rhododendrons, and Herbaceous Plants," which was published by Messrs. Blackwood and Sons in 1875. It was a thoroughly practical book, and, besides many valuable notes on the subjects embraced in the title, treats of other American-flowering shrubs in a lucid way.

He had a special knowledge of Rhododendrons, Ivies, small shrubs generally, and ornamental trees. Mr. Fraser is survived by two daughters and two sons, the latter being in the United States. One who knew him for forty years said: "We were acquainted for upwards of forty years, and we parted as we met—friends." This was the feeling of all who knew him. A large number of friends attended his funeral at Rosebank Cemetery on the 16th inst.

MR. THOMAS W. EMERSON.

MR. THOMAS W. EMERSON, one of the oldest seedsmen of New England, died on the 28th ult. at the age of seventy years. Mr. Emerson was born in Windham, N.H. When a young man he served as a clerk in the agricultural warehouse of Nourse, Mason, and Co., the predecessors of the Ames Plow Company, after which he established himself in the seed business in Boston, holding a position high in the trade for forty years. He was the best known man in Boston in the specialty of field seeds, did an immense business therein, was a member of the Boston Chamber of Commerce, and was one of the most esteemed and popular men in the seed trade. One daughter—Mrs. Gardoer Murphy—survives him.

MR. W. RATCHELOUS.

By the death of Mr. Ratchelous, on the 22nd inst., St. Neots loses one of its foremost townsmen. He was the secretary of the St. Neots Horticultural Society, and also of the Chrysanthemum Society, both of which offices he had held for a long time, while he took a deep and active interest in institutions connected with the town. He had been under medical treatment for some months, but, being a man of considerable vigour, it was hoped he would have recovered, but a quick relapse set in, and he died as above, at the age of 58 or 60 years. A member of a family always much respected in the neighbourhood, and connected with gardening, his father having been gardener at Priory Hill many years, he commenced to work in the garden when quite young, and was eventually gardener at Waresley Park in the district. For the last thirty years he had acted as manager of the St. Neots Nursery of Messrs. Wood and Ingram of Huntingdon, where he was a most successful grower of Cucumbers for seed. As a judge his services were much in request. He acted as local secretary for the Sandy Horticultural Society, and had been a judge at the Sandy flower show for many years. He will be sorely missed by his employers. He leaves a wife and grown-up family.

MR. BENJAMIN WELLS.

THE death is announced of Mr. Benjamin Wells, nurseryman, of Crawley, and formerly of Forest Hill. Mr. Wells was found dead in a well near his house. He was nearly seventy years of age, and had been unwell for some time.

**Annual outing of the Societe Francaise d'Horticulture.**—The summer excursion of members of this society, on a date in June or July yet to be fixed, will be to East Burnham Park, Slough, the residence of Harry J. Veitch, Esq. They will find much of interest in the gardens there, which have been greatly altered of late years.

**East Ham Amateur Chrysanthemum Society.**—This flourishing East End society, which was started in January, 1903, has proved so successful that after defraying the expenses of the year's working, which included a very successful exhibition, the committee have handed over to the East Ham Hospital the sum of £18 15s. 3d., and carry forward a balance of £2 7s. 2½d. Evidently there is no misgiving as to the future of the society.

**National Chrysanthemum Society.** The annual general meeting of the members will take place at Carr's Restaurant, 265, Strand, W.C., on Monday, February 1, at seven o'clock in the evening, Charles E. Shea, Esq., president, in the chair. Agenda: To receive the committee's report and

balance-sheet; to elect a president, vice-presidents, officers, an auditor, and one-third of the committee for the year ensuing; and to transact such business as pertains to the annual general meeting.

**Piedmont Horticultural Society's Jubilee.**—A preliminary notice of the Jubilee exhibition of plants, flowers, fruits, &c., to be held by the Piedmont Horto-Agricultural Society, has already appeared in a former issue. We are now able to state that the dates have been definitely fixed for May 10 to May 25 next, and that the show will be the first of its kind ever held in Italy. The Municipality of Turin has generously placed the Valentino Park, in that city, at the disposal of the executive of the Piedmont Horto-Agricultural Society, and a very fine display is expected. The show is intended to be international in fact and not in name only, and the executive are very desirous that any amateur or professional horticulturist who wishes shall exhibit. Schedules, which are very comprehensive, include 289 classes, and can be had on application to the secretary. In the hope of being able to secure some material support from Great Britain, Mr. Radaelli, vice-president, and Mr. Roda, Commissary-General, intend shortly visiting this country. In the meantime intending exhibitors may get full particulars from the secretary direct—Rue Stampatori, 4, Turin, Italy.

**SOCIETIES.**

**GARDENERS' ROYAL BENEVOLENT INSTITUTION.**

The annual general meeting was held on the 21st inst., at the Covent Garden Hotel, Mr. Harry J. Veitch, treasurer of the institution, presided, and there were some twenty-five persons present, including Dr. Masters, Messrs. Arthur Sutton, P. C. M. Veitch, G. Paul, N. F. Barnes, J. McIndoe, George Monro, Jesse Willard, E. T. Cook, H. G. Cox, W. Baker, J. H. White (of Worcester), and others.

The following is the report for 1903:—

**REPORT OF THE COMMITTEE FOR 1903.**

In presenting their annual report and statement of accounts (as audited) for the year 1903, the committee have the pleasure of again congratulating the members and subscribers of the institution on its continued success and increased usefulness in affording relief both of a permanent and temporary nature to those who, through sheer misfortune, due to accident, ill-health, old age, and reduced circumstances, have been compelled to apply for its assistance in their time of need.

At the beginning of the year 204 persons—being fourteen more than at the corresponding period in the previous year—116 men and 88 widows were receiving life annuities of £20 and £16 respectively. Of this number during the year sixteen have died—nine men and seven widows. Six of the men left widows, whose cases were such as to warrant their being placed on the funds for the widow's annuity of £16, without election, and in accordance with Rule III. The committee have also reinstated on the funds a former pensioner, who had voluntarily relinquished his pension for the time being on account of his altered circumstances. There were thus at the close of the year 192 pensioners on the funds, and the committee recommend an election this day of twelve additional pensioners to fill the vacancies created.

They much regret that in view of the present income, and having regard to prudence, they are unable to recommend the election of a larger number, the more so as the list of candidates shows so large an increase on that at any previous election, but they would remind the subscribers that no less than twenty-eight additional pensioners were placed on the funds in the Coronation year (1902), which materially added to the liabilities of the institution.

The special funds, viz., the Victorian Era Fund and the Good Samaritan Fund, are, happily, still a source of incalculable benefit and help. From the former fund, £135 10s. has been distributed during the year to the unsuccessful candidates who had previously been subscribers, in proportionate amounts, according to the number of years they had subscribed; and from the latter fund, which is for the assistance of subscribing and also non-subscribing applicants, no less than £81 has been awarded in temporary assistance in cases of urgent need, many of which were of a particularly distressing and pathetic character. The grateful letters which have been received from the recipients of aid from these special funds, as well as from the general fund, show how much the help was needed, and how greatly it was appreciated.

The committee would also refer to the generous and thoughtful kindness of Mr. N. N. Sherwood, a trustee and member of the committee, who at the last election presented each unsuccessful candidate, who had been a subscriber, or the widow of such, with the sum of £5. Mr. Sherwood's generous liberality proved most acceptable and was greatly valued.

The annual festival dinner, which took place in June, under the presidency of the Right Honourable the Earl of Warwick, was very successful, and resulted in a substantial sum being raised in aid of the funds, and the committee are much indebted to his lordship. They also take this opportunity of tendering their best thanks to the stewards, collectors, donors of flowers, the Horticultural Press, and to other friends and helpers throughout the country, who in any way, either directly or indirectly, contributed to the success of the festival. The committee have likewise to express their

grateful thanks to the Earl of Ilchester for kindly allowing his beautiful gardens at Holland House to be opened—on the occasion of the flower show of the Royal Horticultural Society—to the public, part of the proceeds obtained therefrom being handed over in aid of the funds of the institution.

The several auxiliaries, viz., Bristol and Bath (hon. secretary, W. J. Harris), Worcester (hon. secretary, Mr. Percy G. White), Devon and Exeter (hon. secretary, W. W. Mackay), Wolverhampton (hon. secretary, Mr. R. Lowe), Reading (hon. secretary, Mr. H. G. Cox), and Liverpool (hon. secretary, Mr. R. G. Waterman), still continue to be a source of strength and much support to the institution, both financially and by creating a wider interest in the work, and the committee gladly record their gratitude to the hon. secretaries and local committees for their kind and much-appreciated services.

It is with deep regret the committee have again the melancholy and sorrowful duty of referring to the many losses amongst the friends and supporters of the institution they have sustained during the past year—losses which will be severely felt, and vacant places it will be difficult to fill. Nevertheless they feel confident that the friends of the institution who remain will not relax their efforts, but will use their utmost endeavours to fill up the gaps in the ranks of those who so kindly and generously assisted to maintain the work. There are at this election no fewer than fifty-three applicants, and if only twelve are elected, forty-one must perforce, beyond what assistance may be afforded from the special funds, to which allusion has already been made, wait for another year before they can again apply for the aid they seek.

Their cases are most sad, and the committee sincerely wish it was in their power at once to grant them, or at least some of them, that permanent assistance for which they plead and of which they are so much in need. The committee, therefore, whilst thankfully acknowledging the help afforded them in the past, very earnestly appeal to all friends and well-wishers for their co-operation in obtaining additional support for this national horticultural charity so as to warrant an enlargement of its beneficent objects on behalf of those, in their days of need, who in their time have done their best to minister to the pleasures and necessities of others.

T. SWIFT.  
J. WILLARD.

Mr. Veitch, in moving the adoption of the annual report and balance-sheet, said although they would have been glad to be able to put more applicants on the list of pensioners, they still had cause for congratulation, for although the number of applicants was larger last year than ever before, they had also been able to put on more than on any other occasion. Mr. Veitch emphasised the necessity of doing all they possibly could so as to reduce the number of unsuccessful applicants. They had had no complaints about the alterations in the rules; if the committee felt that at some future time the rules needed further alteration, then they would appeal to the meeting again. The chairman said how desirous it was that gardeners should join the institution when they were young, the younger they were upon joining the more votes they would have to their credit. They wanted more money for the Victorian Era Fund, as was shown by the fact of there being so many unsuccessful applicants. Mr. Veitch said how very grateful they were to Lord Ilchester for throwing open his beautiful gardens at Holland House to the public and giving the proceeds of the admission charges to the gardening charities. This year Lord Ilchester has promised to allow a local hospital to benefit, but in 1905 he promised that the gardening charities should again benefit. They were also very grateful to Mr. Sherwood for his liberality to unsuccessful candidates last year. The chairman referred to the valuable help afforded by the auxiliaries, to whom they were very grateful. Since the voting papers were issued two of the candidates had died, so they would ask for two others to be put on. Also providing Thomas Cridland, aged 74, blind and unsuccessful seven times, was not elected they would ask for him to be put on the list of pensioners. Mr. Veitch said that he had been invited to preside at the annual festival dinner in June next, and he hoped that he should have the full support of all members and friends. Mr. Arthur Sutton seconded the resolution (which was passed *nem. con.*), and said he thought it would be a good thing to put in the report the amount of money each auxiliary had forwarded; he thought this would act as an incentive, and be productive of increased help.

Mr. Arthur Sutton proposed that Mr. H. J. Veitch be re-elected treasurer of the institution, and that their best thanks be given to him for his services. Mr. Sutton eulogised Mr. Veitch's services to this institution, and said what immense help he had given. Mr. N. F. Barnes seconded this proposition, remarking that the interests of the institution were safe in Mr. Veitch's keeping.

Dr. Masters proposed the re-election of the secretary (Mr. G. J. Ingram). This was seconded by Mr. Vallance and carried unanimously.

Mr. Baker proposed that Messrs. W. Crump, M. Gleeson, James Hudson, A. Mackellar, R. Piper, S. Segar, N. F. Barnes, P. C. M. Veitch, and W. Y. Baker be re-elected members of committee, and that Messrs. J. H. Veitch and J. Laing. Mr. G. Monro seconded this, which was unanimously carried. The auditors, arbitrators, and scrutineers of the ballot, the latter being Messrs. Edmund Monro and Joseph Rochford, were then elected.

Mr. Arthur Sutton very generously offered to give a year's pension to one of the unsuccessful candidates, to be appointed by the committee, an offer that will undoubtedly bring great joy to the recipient.

**RESULT OF THE POLL.**

Henry Cross, 3,423; William Chambers, 3,545; Abram Stansfield, 3,444; Frederick Smith, 3,300; Eliza E. Doherty, 3,297; Richard Nisbet, 3,224; Jane Edwards, 3,186; Henry Rabbitts, 3,091; William Turner, 2,906; James Worthington, 2,955; Richard Skuner, 2,902; Edward Foster, 2,842; Andrew Armstrong, 2,838; George Dale, 2,796; William Smith, 2,784; and Thomas Cridland, 1,816.

There were 28 unsigned papers totalling 200 votes, and 3 papers giving 15 votes more than they were entitled to. Votes of thanks to the chairman and scrutineers of the ballot closed the meeting, and at 6 p.m. the

**ANNUAL FRIENDLY SUPPER**

was held in the hotel, Mr. Leonard Sutton of Reading presiding. Among those present were Messrs. Harry J. Veitch, W. A. Biley, Edward Sherwood, George Bunyard, George Paul, H. B. May, George Monro, G. Asbee, N. F. Barnes, P. C. M. Veitch, Arnold Moss, Peter Kay, S. Segar, Anderson, Morgan Veitch, E. J. Monro, Duncan Tucker, J. McIndoe, Denning, S. T. Wright, W. Roupell, H. Cox, G. J. Ingram (secretary), and others.

After the loyal toasts, Mr. Leonard Sutton proposed "Continued Success to the Institution." Mr. Sutton said that successful candidates would by now have had news of their election, and would feel unbounded gratitude to this institution for its timely help. The chairman referred to the Prince of Wales's famous speech at the Guildhall, in which he said that England must "wake up," and said that the gardening public should wake up and help this splendid institution. At Reading they had tried to do this, and had established a very successful auxiliary. The auxiliaries were very valuable, as they are a link between the committee in London and people in county districts. Mr. Sutton thought small amateurs were the people to get hold of, and he was glad to hear that a leaflet was to be put through the Journal of the Royal Horticultural Society. Only £3 per annum is spent in advertising the Gardeners' Royal Benevolent Institution, and Mr. Sutton said he would like to make a special subscription for advertising its claims, and about which he would consult with the secretary. He thought an enthusiastic committee as they had was one reason of the success of this institution. They were trying to get all the members of their Gardeners' Society at Reading to subscribe to the Gardeners' Royal Benevolent Institution. The chairman concluded by coupling the name of Mr. Harry J. Veitch with the toast.

\* Put on by committee in consequence of the death of two candidates since the voting papers were issued.

† One year's pension given by Mr. Arthur Sutton, Reading.  
‡ Placed on the list of pensioners by committee by a rule which gives them power to elect any unsuccessful candidate they may choose.

# THE GARDEN

No. 1681.—Vol. LXV.]

[FEBRUARY 6, 1904.]

## ROYAL HORTICULTURAL SOCIETY.

ON Tuesday next the Royal Horticultural Society will hold its annual general meeting. This is the hundredth year of its existence, and all who have the welfare of this great horticultural organisation at heart will enter into the spirit of the occasion, and allow the proceedings to pass off without anything in the nature of a hostile attack upon an overburdened and faithful council. This meeting should be one of peace, and a hearty vote of confidence to those who govern its affairs will do much to help the two great funds the council have in hand, namely, for the Hall and the Wisley Garden. It has been whispered, though perhaps there may be no truth in it, that the formation of a scientific department at Wisley will be hotly opposed, in the belief that all work of this character should be carried on at Kew. We have the greatest admiration for the botanical and other work accomplished in the Royal Gardens, but we cannot think that a scientific department at Wisley will cause the slightest jealousy at Kew. This department will be simply to encourage research in matters affecting the garden, diseases of plants and so forth, with no intention whatever of setting up an opposition shop.

Those who have the affairs of the society under their control would not place themselves in a position so ridiculous and impossible. The work would be similar to that undertaken in the Botanic Gardens at Regent's Park, and the more we have of such organisations for the encouragement of scientific study the better for our farms and gardens.

We are sorry to find that Baron Schröder has been compelled to issue a second appeal on behalf of the Hall fund. We hope his earnest efforts to reduce the still heavy outstanding amount or wipe it off altogether will meet with a liberal response; and the garden also will cost a considerable sum for its lay-out and up-keep. The more urgent of the two funds is that of the Hall, and visitors to the annual meeting are invited to inspect the new building.

The new Hall will prove a boon to the many special societies that are constantly appealing to the Horticultural Club for the use of its rooms at the Hotel Windsor. The club is a refuge for various societies and committees,

and requests for its use are frequently granted, sometimes with considerable inconvenience to the members. The rooms at the new Hall will, we presume, be the meeting-ground in the future.

The society during the past few years has flourished amazingly, for the simple reason that its watchword is "Horticulture." It is the great centre for horticultural exhibitions, lectures, and meetings, and the garden at Wisley will represent the practical side of its work in promoting trials of fruits and vegetables, developing the scientific department, and laying the foundation of a school for gardening, managed by practical men.

We must confess that raising the subscription to £2 2s. will not please the country members, and the council may expect some opposition from those who cannot enjoy the delight of visiting the fortnightly meetings and the great exhibitions, though we venture to think no society in the world gives so much for the sum of £1 1s. a year. The Journal itself is worth more than that, and it must be remembered, to repeat the words in the report, "Free advice" is given "on all ordinary garden subjects; investigation of plant diseases, &c., by the scientific committee; a share of plants at the annual distribution; facilities for chemical advice, &c."

## THE LILIES.

### LILIUM ELEGANS (THUNB.).

**VAR. ATROSAUGINEUM**, the Dark Blood-red *L. elegans*.—A form of the variable var. *fulgens*, grows 18 inches high, flower-buds and growth quite woolly, the leaves ascending. Flowers two to four, narrow petalled, not expanding fully, coloured blood-red, heavily spotted darker low down, the tips alone being free from spots. Flowers late in July. Common in cultivation.

**Var. Batemanniae** (Mrs. Bateman's Apricot Lily).—A tall-growing plant, suggesting hybrid origin. The stems are 2 feet to 3 feet high, clothed with narrowly lance-shaped, recurving leaves, and bearing four to six rich apricot-coloured, widely expanding flowers of great beauty, quite unspotted, and arranged in a pyramidal spike. The petals are broad, elegantly recurved, and their margins are undulating. A lovely Lily, blooming in late August. The bulbs are large, and much prized as an article of food in Japan. Common in cultivation.

**Var. Beautiful Star** is a newer garden form of *atroanguineum* type. Its stems are 18 inches high, and they bear three to six very large

orange-red flowers 6 inches to 7 inches across the petals.

**Var. Beauty** is a kindred plant; the flowers are of a paler orange shade, with reddish flushing near the tips. Both flower in July, and either variety is rare in cultivation.

**Var. bicolor** (Moore) (the Two-coloured *L. elegans*) is a dwarf variety; the season of flowering varies considerably. Stems 1 foot high, flowers one to three, broad-petalled, expanding fully, but thin in texture, the tips alone reflexing; colour crimson, buff below; a lilac sheen suffuses the inner surfaces shortly after they expand, and a few irregular splashes of crimson adorn the tips. A very beautiful variety, but very fleeting. Flowers in July, but a few stragglers bloom in August and September. Its colouring and season of flowering are uncertain. Common in cultivation.

**Var. bilijulatum**.—See var. *sanguineum*.

**Var. brevifolium** (Baker and Dyer).—The short-leaved *L. elegans* is a very difficult variety to manage successfully. Its growth is precocious, and the leaves and buds are often "bit" by late spring frosts. It does not grow well in pots, and as its flowers are small it is scarcely worth cultivating. It grows 12 inches to 18 inches high, and has cup-shaped flowers, the petals of which are narrow and distant; coloured a pale red, and dotted low down with black. Frequent disaster to the leaves in a young state gives the plant no opportunity of building up large bulbs that would flower well and develop their true quality. Flowers in May. Common in cultivation.

**Var. citrinum**.—See var. *armenaicum*.

**Var. coruscens**.—See var. *atroanguineum*.

**Var. E. L. Joerg** is a robust, large-flowered hybrid, 18 inches high; leaves stout, recurving, thickly arranged on the stems; flowers three to six, crimson, with a spoon-shaped patch of yellowish buff in the middle of each broad petal. The stems often travel several inches underground before appearing, and this feature, together with its large, deeply cup-shaped flowers and large bulbs, indicates var. *Wilsoni* as a parent. A fine garden Lily, blooming in late August. Common in cultivation.

**Var. fulgens** (Morren).—This is a very popular form on the Continent; in this country we find *atroanguineum* stronger and better. Its stems do not exceed 9 inches in height, and they bear two to five thin-petalled flowers, coloured a brick red, the petals being quite narrow and distant, and they expand fully. A dark chocolate spotting occurs near the centre of each, and a marbling of yellow suffuses the outside of the flowers.

**Var. flore-pleno**. Its double form is a singular plant, with the stamens partially transformed into petals; this coloured similarly to the type, but the filling of smaller petals in the centre is tipped with white. It cannot be recommended as a beautiful garden plant, but many would value it as a curiosity. It often finds its way to popular auction rooms as "the wonderful

Bird's-nest Lily of Japan," accompanied by a very lavish description of its beauty, and some romantic accounts of its origin. Common in cultivation. Flowers in July.

*Var. Horsmanii* (Horsman's L. elegans) is a very richly-coloured form, now very rare. The plant is none too vigorous, hence its scarcity; the flowers expand fully, their petals being broad and spoon-shaped, highly polished, and their colour is the deepest crimson-maroon imaginable. A splendid variety, but almost extinct. Rare in cultivation. Flowers in July.

*Var. Kikak.*—See alutaceum and marmoratum.

*Var. marmoratum* (the Mottled L. elegans) is an old variety, one of the earlier forms introduced from Japan. It grows 10 inches high, and bears two to four deep crimson broad-petalled flowers 6 inches across, tipped and spangled yellow on the inner surfaces, the outer colouring being yellowish buff and quite undecided, and the whole plant is woolly.

*Var. marmoratum aureum* (the Golden Mottled L. elegans)=*var. robustum* is a Lily of strong growth, and densely covered with a silky covering in a young state. Its stems are 18 inches high, and they bear three to six broad-petalled flowers that expand widely and are yellow in colour, densely spotted from tip to base with deep red; a few flecks of red and a little deeper shading occur on the outside. Heavy rains at the time of flowering bleach the petals badly. It grows very freely and increases fast, and its colouring is brightest when the plants grow in peat or heath soil. Very common in cultivation. Flowers in June and July.

G. B. MALLETT.

(To be continued.)

## NOTES ON HARDY PLANTS

### TEUCRIUM FRUTICANS.

ONE can hardly think that "S. G. R." will find *Teucrium fruticans* a suitable shrub for his group of blue plants. For one thing, it is not bright enough to be called a real blue, and the silvery appearance of the under sides of the leaves, the greyness of the upper part of the foliage, and the pale colour of the flowers would make it more suitable for a "grey garden." Then, with me it has never assumed a true, erect habit, although this may be partly owing to its being occasionally cut back by frosts. From what I have seen of it elsewhere it appears to be more suitable for a wall than for planting in the open. I have had it here for several years. It is pretty in every way, but hardly what is wanted by your correspondent.

### MITRARIA COCCINEA.

IN some respects gardeners are fortunate whose lot is cast in the warmer districts of the kingdom, for they can hope to cultivate in the open air many plants which those in the colder parts can only induce to grow when under the protection of glass. That this is a great advantage few will gainsay, as in the open these plants often look more at home, and are less liable to the attacks of pests than when under glass. Among the plants which are unmanageable in the open air in the greater part of these isles, but which thrive in such parts as the Exeter and coast districts of Devonshire or Cornwall, the south of Ireland, and in a few places in the west of Scotland, such as at Inverewe Poolwee, is *Mitraria coccinea*, which is not only well worth growing in these favoured districts, but deserves the protection of glass in colder places. It is one of the most brilliant of a number of showy plants which have come to us from Chili and its dependencies. It is a handsome evergreen shrub with

brilliant scarlet flowers. These are produced from the axils of the leaves on long foot-stalks, and, to use a familiar illustration, remind one in form of the blooms of a Foxglove, with the long style protruding from the mouth of the tube. The leaves are small, and of a pretty green. It usually begins to bloom late in May, and may continue until July if the weather is favourable. A good, well-established plant will grow to 3 feet or 4 feet in height. In the districts already mentioned the *Mitraria* may be cultivated against a wall, but it prefers some shade, so that this should be studied in planting. In especially favoured localities it may be cultivated as a bush, but this is not prudent everywhere. It likes a soil of good turfy peat and loam, either in the open or when grown in pots. It dislikes an arid atmosphere, either in the open or under glass. *Mitraria coccinea* is more easily propagated than many other plants of shrubby habit, as it may be increased by dividing the roots in spring, or by cuttings struck under a bell-glass in light soil in summer. It is a shrub which especially deserves some notice at the hands of those whose gardens are situated in the warmer parts of Great Britain and Ireland, and no one who succeeds with it will ever regret its possession.

### GALANTHUS CILICICUS AND G. OCTOBRENSIS.

THIS handsome Snowdrop flowered here in the autumn of 1902 from bulbs imported that year from its native habitats, but this year the same bulbs did not bloom until about the same time as those of your correspondent "F. H. C." Many newly imported bulbs flower earlier the first season than in succeeding ones, and thus it is hardly prudent to expect that *G. cilicicus* will again bloom in November with us. At the same time, it may be noted that in its native habitats *G. cilicicus* is in flower from November to March. As you remark in your editorial note, *G. cilicicus* is a species from Cilicia, and *G. octobrensis* a variety of the common Snowdrop. *G. octobrensis* has the white line down the centre of the leaf, which distinguishes most of the autumn-flowering varieties of *G. nivalis* from those which bloom in spring. My experience of these autumn Snowdrops is that they are gradually assuming the habits of the common Snowdrops, and bloom later and later almost each year. Even in the United States they seem to be adopting the same habit, as Mr. J. N. Gerard of New Jersey has a remark to this effect in a recent issue of *Country Life in America*. S. ARNOTT.

*Carsethorn, by Dumfries, N.B.*

## NOTES OF THE WEEK.

### FORTHCOMING EVENTS.

February 8.—United Horticultural Benefit and Provident Society Committee Meeting.

February 9.—Royal Horticultural Society's Drill Hall Meeting; Annual Meeting at 3 p.m.; Horticultural Club Annual Meeting, 5 p.m.; Annual Dinner, 6 p.m. Sir John Llewelyn, Bart., chairman of the club, will preside.

February 10.—East Anglian Horticultural Club Meeting.

February 12.—Royal Gardeners' Orphan Fund Annual General Meeting.

February 23.—Royal Horticultural Society's Drill Hall Meeting, 12 noon.

March 8.—Royal Horticultural Society's Drill Hall Meeting.

March 9.—East Anglian Horticultural Club Meeting.

**The Horticultural Hall Fund.**—Baron Sir Henry Schröder, Bart., has issued a second appeal to those who have not subscribed to the Hall fund, and we hope the response will be a liberal one.

**Royal Horticultural Society.**—The next meeting of the committees will take place on Tuesday next, the 9th inst., in the Drill Hall, Buckingham Gate, Westminster. The annual general meeting of the Fellows of the society will also be held in the Drill Hall at 3 p.m. on the same date.

Fellows attending the meeting are invited to inspect the new Hall now building in Vincent Square. At a general meeting held on Tuesday, the 26th ult., 119 new Fellows were elected, amongst them being Lady Hindlip, Lady Wynford, and Sir John Aird, M.P., making a total of 172 elected since the beginning of the present year.

**The Royal Horticultural Society and the trade.**—We understand that since the issue of the Royal Horticultural Society's report, and the issue of an appeal for funds for the new Hall by Baron Schröder, the society's offices have been bombarded with letters to the following effect: "May I express a hope that those members of the trade who make such liberal use of the society, either at the Hall, or at the Temple, or Holland House, for their exhibits, should be called upon either to support the funds in a handsome manner directly, or be made to do so indirectly by having in future to pay for all space allotted to them at shows. For I have noticed in looking over the subscription list for the new Hall that several who are most constant and liberal in their application for space for their exhibits are equally conspicuous by the absence of their names from the list of subscribers."

**Rainfall in 1903.**—I have sent you the rainfall taken in these gardens. I began to make notes in the year 1879, but 1903 is by far the greatest fall for twelve months. The average for this part in fifty years is 24.95 for the twelve months, but in 1903 we got 41.14 for the year, and 171 days on which more or less rain fell.

Month.	Total	Greatest fall	Number of	
	depth.	in 24 hours.	days on which '01 or more fell.

—W. J. TOWNSEND, *The Gardens, Sandhurst Lodge, Wellington College Station.*

**The annual New Year gathering** of the employees of Messrs. J. Hill and Son, Lower Edmonton, took place at the residence of Mr. J. E. Hill on the 21st ult., when about thirty were entertained to dinner. After the toast of the firm had been enthusiastically honoured, Mr. Hill referred to the anxiety caused during the past year by the floods. Mr. Hill acknowledged his indebtedness to the men who so willingly and cheerfully helped him to overcome the difficulties they had experienced from time to time. He believed that 1904 would turn out better than 1903, and, with their help, hoped the firm would surpass all previous years. Remarks were also made by Mr. J. Maton, Mr. Worthington, and Mr. Stuart (foreman), the latter, in moving the best thanks of the employees to Mr. and Mrs. Hill for their kind entertainment, testified to the kindly feeling existing between master and men. Music followed, and a thoroughly enjoyable evening was spent.

**Damage by rain.**—The English farmer is in despair. After the ruinous floods of autumn he hoped for a good seeding time, but it is proving one of the worst within recollection. Where the constant rains are not washing away the seed they are rotting it or preventing its maturing. In Essex and Lincolnshire particularly the outlook is very gloomy. Several farmers in the former county have ploughed up large quantities of Wheat sown in the autumn, as there was no prospect of it growing. Greenstuff left standing for seed production is being similarly affected. Horticulturists also are complaining bitterly. "Somehow," remarked a leading Covent Garden dealer recently, "people's minds do not turn to flowers when the weather is dull and rainy. One would think that the gloomier the conditions outside the brighter the people would try to make their homes. But the contrary is the rule."

**The Woodland Plants of Scotland.**

The last monthly meeting of the Edinburgh Field Naturalists' and Microscopical Society was an unusually interesting one to many. A valuable paper on "The Rarer Woodland Plants of Scotland" was read by Mr. David S. Fish, of the Edinburgh Royal Botanic Gardens. It dealt in an exhaustive and able manner with the characters of the different woodland growth, and gave interesting details of the rarer plants to be found. Among the plants spoken of were *Pyrola niflora*, *Linnaea borealis*, and *Trientalis europæa*. Their liability to destruction by the cutting down of the trees under which they thrived, and the effect produced by the planting of other trees, were dealt with and illustrated with lantern views. The lecture was worthy of a wider audience. Another interesting feature of the meeting was an exhibit by Mr. J. Fraser of specimens of 250 alien plants collected by him last year, principally near the Leith Docks.

**A winter-flowering Wallflower.**

—Everyone appreciates Wallflowers in the spring, and there can be little doubt that the winter-flowering Wallflower will be made welcome. Messrs. James Veitch and Sons, Limited, Chelsea, exhibited a small group of it at the last Drill Hall meeting of the Royal Horticultural Society. The name of this new Wallflower is *Cheiranthus kewensis*, a hybrid between *C. mutabilis* and the garden Wallflower; the flowers vary in colour, pale purple predominating, and they are sweetly scented. It will undoubtedly be largely grown when better known, for the Wallflower is such a general favourite that a greenhouse winter-flowering one cannot fail to be made much of.

**The Citron and Shaddock in vineries.**

—I note in THE GARDEN of last week, page viii., a report of Mr. Somers Rivers' lecture on the above family, and it is recommended to grow them on the back walls of vineries. Grown thus they give very little trouble indeed. When I lived in the Midlands we had them growing in this way, and they were much valued for preserving, making a delicious compôte for the winter dessert. Few plants thrive more freely in a narrow, shallow border if the back wall of the house is not too much shaded, as, though a little shade is not injurious, if there is too much the flowers do not set freely. I have also noticed that the extra warmth given to the Vines in the spring suited the plants when in bloom. I have frequently seen Orange trees fail to set simply because there was insufficient warmth. When the fruits are almost full grown they are, as it were, stationary, and less heat is required, but when new growth begins the trees repay liberal treatment. My reason for sending this note is to point out the value of the Citron for preserving, and the fragrance of its flowers is much liked by many, but it requires a shallow border. If grown in pots or tubs it should get ample drainage. I am unable to say if the Kumquat was noticed at the lecture. This is *Citrus japonicus*, and, though less seen than any of the others, it is useful for the cool house and will stand cold. We have fruited it in a cold house, and I have seen it growing freely in Cornwall and Devon in the open.

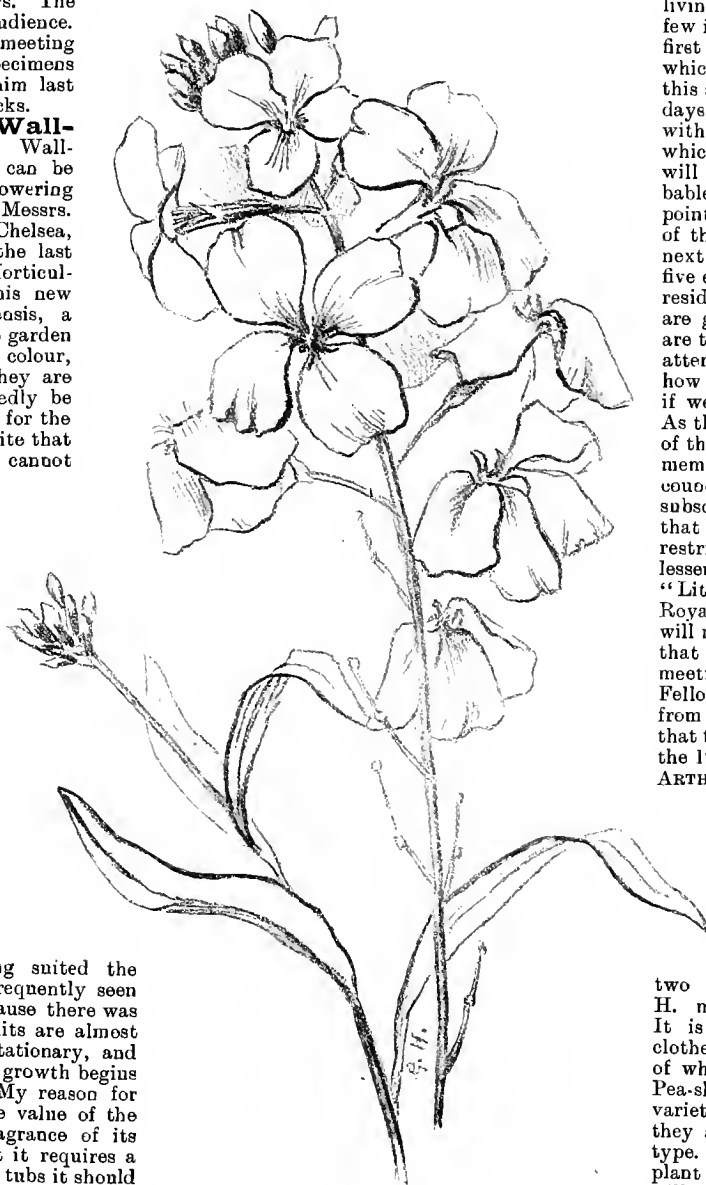

**The Gardeners' Royal Benevolent Institution.**

—The excellent leader in THE GARDEN, page 67, will, I trust, be read far and wide, and it should cause many who only know the institution by name to take a greater interest in its welfare. Your statement that only 1,000 gardeners are members shows the need of such articles and of forming auxiliaries in different centres. I am glad you appeal to the gardener, and if they note that 100 votes are given for each sub-

scription, it will be seen that they are well repaid when adversity befalls them. They will then find they have not invested their savings badly, and if they have only helped others by so doing they will have done good work. At times the committee is blamed because subscribers do not get enough consideration, but this is not so now. At the same time, we must not forget the term "benevolent," and that the widow of a subscriber receives full justice.—G. WYTHES, *Syon Gardens*.

**Dunfermline Carnegie Trust.**

—Many will watch with great interest the developments of the operations of the Dunfermline Trust, established through the munificence of Dr. Andrew

A WINTER-FLOWERING WALLFLOWER (*CHEIRANTHUS KEWENSIS*). (Natural size.)

Carnegie, and to many the horticultural side will appeal strongly. At a recent meeting of the trustees some progress was made in the direction of furthering this part of the work. Professor Geddes is engaged in the preparation of a report on Pittencrieff Glen and Park, and a first instalment of his report was considered and remitted to a committee for further consideration. A committee of five was also appointed to consider the giving of prizes for gardens, flower-plots, and window-boxes, and the advisability of holding special horticultural exhibitions in Dunfermline. A donation of £10 10s. was voted to the funds of the Dunfermline Chrysanthemum Society.

**The Royal Horticultural Society and its subscription.**

—Will you allow me to thank a number of correspondents who have written to me expressing their agreement with my views of the extraordinary reversal in the policy of the council in the last twelve months? So far only one of my correspondents disagrees with my views, and he asks why should new members who have paid nothing towards a hall which will cost over £40,000, and a garden which will cost £10,000, be allowed to join on the same terms as those who have, and receive each year £12 4s. 6d. in exchange for a paltry guinea? I am afraid that the table in the society's report, which was reproduced on page 68 of THE GARDEN, is not convincing to any Fellows living a good way out of London. I will analyse a few items just to explain what I mean. In the first place, take the Temple show, the value of which expressed in tickets is £1 13s. To secure this sum each Fellow must attend the show three days, and dispose of all his spare tickets; so also with the Holland House show, the tickets for which are put down at the value of £1 10s. We will suppose (which is, of course, wildly improbable) that three-quarters of the Fellows make a point of attending these shows as well as disposing of their tickets, and let the figures stand. The next item we come upon is £7 11s. 6d. for twenty-five exhibitions. Here I think that Fellows who reside a long distance from London (of whom there are great numbers) may well object. How many are there who can afford the time or the money to attend even half of the fortnightly meetings, and how much would it cost in fares and other expenses if we were fortunate enough to be able to attend? As the Editor has rightly said, the ordinary events of the society are of little interest to many country members. In a word, the future policy of the council is to force the country members to pay a subscription out of all proportion to the benefits that most of them can possibly receive, so as to restrict the membership of the society, and thus lessen its hold upon horticulturists. Surely this "Little England" policy is not worthy of the Royal (*i.e.* National) Horticultural Society. It will not be in any spirit of hostility to the council that I shall move an amendment at the general meeting that no alteration be made in the £1 1s. Fellowship for Fellows residing 100 miles or more from London, but because at the present time I feel that the right policy of the society was expressed in the 1902 report, to which I referred last week.—ARTHUR R. GOODWIN. [The Editor is not responsible for the opinions of his correspondents.]

**Hardenbergia monophylla.**

Though there are only two species of *Hardenbergia* in cultivation the list of synonyms is a long one, and besides this they are sometimes included in the genus *Kennedy*. Both of them are climbing plants, the less vigorous of the two being that at the head of this note—*H. monophylla*—which is just now in flower. It is of slender growth, and has wiry stems clothed with simple ovate leaves, from the axils of which are produced drooping racemes of small Pea-shaped rosy purple flowers. There is a variety (*alba*) in which the flowers are white, and they afford a decided change from those of the type. This is well suited for a pillar or rafter plant in a small or medium sized greenhouse, as it will not soon outgrow its allotted space, and does not obstruct much light at any season. The second species—*H. comptoniana*—is more vigorous, while the leaves are trifoliate, and deep shining green. The flowers, crowded together in racemes about 4 inches long, are bright purple, and a succession will be kept up for some time. As an early spring-flowered climber for a larger structure than the last, it is well suited. The culture of these *Hardenbergias* is not at all exacting, given a soil with a good proportion of peat and sand, for like many other Australian Leguminosae, a certain amount of peat is necessary. With regard to the synonyms mentioned at the beginning of this note, *Hungeli*, *digitata*, *Lindleyi*, and *makayana* are now classed under *comptoniana*; and *cordata* and *ovata* under the head of *monophylla*.—H. P.

**John Knox's Yew.**—All Scotsmen will be glad to know that the historic Yew at Finlayston, Renfrewshire, which is associated with the name of John Knox, the reformer, has not suffered from its removal some time ago. As many are aware, Knox conducted a communion service under it in the year 1563, when it was probably an old tree. It has attained a great size, and it was found absolutely necessary to remove it on account of some changes which were to be made in the grounds. The task was rather a difficult one, but Mr. A. Bald, the experienced gardener of Mr. Kidston, took every precaution, and the services of Mr. Barron were also enlisted. As the tree and the soil attached weighed 30 tons, much care was necessary; but Mr. Bald had everything properly arranged, and the venerable Yew was moved to its new position without any mishap. It has not suffered in the least, and this is a gratification to many besides Mr. Kidston.—S.

**Coronilla glauca.**—Probably owing to the fact that *Cytisus racemosus* is grown in thousands by our market nurserymen we do not meet with this *Coronilla* so frequently as formerly, yet the neglect into which it has now fallen is difficult to understand, for it is a delightful flowering shrub for the greenhouse at this season, while not only are the clear yellow flowers so different in arrangement and tint from those of the *Cytisus*, but the pretty glaucous leaves are quite unlike those of any of its associates. It is a native of the South of Europe, and is hardy in some of the most particularly favoured districts of the country, but it is as a greenhouse plant that it claims recognition. It is not difficult to strike from cuttings, and will grow readily in a mixture of loam, peat or leaf-mould, and sand. Careful watering is necessary, particularly in the case of large plants. There is a variety with variegated leaves, but it is less handsome than the type.—H.P.

**Eupatorium vernale.**—This *Eupatorium*, which Messrs. Veitch showed in such good condition among their group of flowering plants at the Drill Hall on the 26th ult., is, though bearing an uncommon name, apparently not a new species, for it is, I believe, regarded as the true name of the plant, which as *Eupatorium grandiflorum* has been in cultivation for some considerable time, though it is very little known. It is certainly one of the best of the genus, and not only is it useful as a pot plant for decorations, but large-sized bushes are valuable where cut flowers are required. The flowers keep well in water. The *Eupatoriums* are all of easy propagation and culture, for they strike readily in spring from cuttings of the young growing shoots, which, after being potted off, must have the tops pinched out and be shifted into larger pots when required. The latter half of the summer, when in their flowering pots, they may be placed out of doors and treated in much the same way as *Salvias*. Being liberal feeders manure water should, as the pots get full of roots, be supplied to all the *Eupatoriums*. For many years *E. riparium* was largely grown, but it cannot be compared with the species under notice, nor with *E. adenophorum*, grown at Kew as *E. trapezoideum*, nor with *E. probum*.—T.

**Colchicum montanum.**—As *Colchicum* sp. from the Taurus, a very pretty and distinct form of this species has been received from Mr. W. Siehe, of Mersina, and is now flowering in the Alpine house at Kew. With unusually short segments, which are very broad in proportion, the plant is quite different from the usual forms in cultivation, which have longer strap-shaped parts of the perianth. The pale purple flowers are globular in form, usually two to each corm, with a tube which is longer than the three broad glaucous green leaves. A native of the Mediterranean region, this species enjoys a wide distribution, and growing thus under various conditions, it is natural that it should vary a good deal. Several plants that have received specific names cannot be definitely separated from this species, being merely distinct geographical forms. Under this might be included the *C. libanoticum* from Palestine, which is usually a larger plant than the type, and coming into flower somewhat earlier. This is probably an

extreme form, and to many would justify its specific rank. Other *Colchicums* in flower are *C. Argei*, from the same source, and a somewhat similar plant, but deeper in colour. *C. hydrophilum*, also from Asia Minor, with dark purple flowers with narrow segments about an inch long; a very free flowering plant. *C. crociflorum*, the rare little *Crocus*-like species from Turkestan, shows a variety of marking in the different flowers, which are produced several to each corm, with three broad green leaves. Some of the flowers have a broad violet-purple line down the centre of the outside of the segment, others have narrow reddish purple lines, and others, again, have several faint lilac lines spread over the outer surface, while the inside of the flower is white. Another plant which is often met with under this name is simply *C. autumnale*.—W. IRVING.

**Iris reticulata Melusine.**—Last August I obtained from Herr Max Leichtlin three new forms of *Iris reticulata* under the names of *luteo-alba*, *Ariadne*, and *Melusine*. They were potted in sandy loam on August 3, and placed in a cool greenhouse. The variety that heads this note came into flower on the 30th ult., and of its exquisite beauty I can scarcely say too much. Herr Max Leichtlin first mentioned it in his "Notes from Baden-Baden" (see THE GARDEN, vol. lxi., page 192), where he describes its colour as "a bright sky blue." But sky blue is usually supposed to be almost a Forget-me-not blue, so that with this description I am not able to agree. The prevailing tone of colour in this *Iris* would be best described as a light mauve-blue, as in the type there is a rich orange stain in the centre of each fall. Around this stain are numerous white veins, while below it the mauve-blue colour deepens to violet. The plant is as deliciously fragrant as the type, and evidently very free, seeing that my one small bulb has produced two flowers. I am eagerly awaiting the flowering of the two other varieties named above, and, as I understand that Herr Max Leichtlin has other beautiful seedling forms to distribute, no doubt we shall soon have a much greater range of colour than we now possess. Indeed, a pure white variety (*Iris reticulata alba*) and an almost black one, which has been named *Negro*, are already promised us. It seems needless to sing the praises of the *Netted Iris*, and yet it is unknown in hundreds of English gardens. For the alpine house or cool greenhouse, as well as outdoors, it is indispensable, and as I write a few of its flowers are filling my room with their delectable scent.—ARTHUR R. GOODWIN, *Worcestershire*.

**A useful spring vegetable (Mercury).**—In the eastern counties Mercury is a favourite spring vegetable, and as it can be grown so readily it may not be out of place to note its culture. Botanically, it is known as *Chenopodium Bonus Henricus*, but its more popular name is Mercury. It is readily raised from seeds sown early in the spring in good land and in rows 15 inches to 18 inches apart, and the plants thinned to half that distance in the row. In rich land more space would give stronger material. At the start it is important to thin the seedlings early, as they soon get weak. The first season the return will not be great, but afterwards there will be a full supply. Plants lifted late in March or early April, and when the best portions are selected and these planted in deeply-dug and well-enriched soil, will provide good material for several seasons, especially if a rich top-dressing is given in the early autumn. This when applied liberally causes the shoots to thicken, and these, when cut under the soil like *Asparagus*, are delicious. Cutting generally begins in April and continues till the end of June. By many the plant is termed *Lincolnshire Asparagus* or *Good King Henry*. To grow it well it must have ample food, and it well repays liquid manure when in growth. The leaves may be used in the same way as *Spinach* when nearly full-grown, but I think the young shoots are much better when cut as advised, namely, in a young state.—G. W. S.

**The famous Kinnell Vine.**—The Vine at Auchmore, Killin, Perthshire, the property of the Marquis of Breadalbane, is reputed to be the largest in the United Kingdom, though there are several much older. It is of the *Black Hamburg* variety, and was planted in 1832. It was grown

some years previously in a pot, but planted out at this date in a small greenhouse. It flourished rapidly and soon became too large, and the house was extended at different periods till it now fills a house 171 feet long by 25 feet wide, and it would be good for the Vine again to enlarge the house, but, unfortunately, this cannot be done without pulling down a block of buildings. It has a clean stem of 6 feet, measuring 2 feet in circumference; then it branches off each way, and rods are trained up the roof, about 3 feet apart, gridiron-shaped, and it is a perfectly shaped plant. It produces about 5,000 bunches annually, and about 600 are left on to ripen. As far back as 1879 800 bunches were allowed to mature, but this was thought to be too heavy a strain on the plant, and for the last twenty years it has ripened on an average 600 bunches. Only 500 were taken last season, but the berries were large and well finished. The bunches averaged about 1½ lb. in weight, but several were cut 3½ lb. in weight. The total weight of crop in 1903 was about 700 lb. It will no doubt surprise many to hear of this monster Vine so far north, because its existence is not generally known.—W. W., *N.B.*

**Ripe Figs for ten months.**—Figs have long been esteemed as one of the most delicious summer and autumn dessert fruits, and of late years they have come into more general favour. This may to some extent be attributable to their more extended cultivation in pots. The greatest advantage derived from this method of cultivation is the much longer season in which ripe Figs may be had. I was recently much interested in the fine lot of Figs as grown by Mr. Sanders at Halton. During the last three months of the past year he was able to gather really nice fruits two and three times a week of such varieties as *Brown Turkey*, *Negro Largo*, *Bourjassotte Grise*, and *Black Ischia*. With three batches of plants in pots to be started at different periods for succession, ripe Figs may easily be had for about ten months of the year.—J. J.

**Grevillea rosmarinifolia.**—The bright coloured *Grevillea* mentioned in THE GARDEN, page 68, is one of the hardiest of this Australian genus, the only other species equal to it being that usually known as *G. sulphurea*, but of which *G. juniperina* is considered to be the correct name. In the south-west of England and in many parts of Ireland these two may be regarded as hardy shrubs, but in the greater part of the country they are greenhouse plants. This amount of protection is well repaid by many other members of the genus, some of which, in addition to their flowers, have very ornamental leafage. Among the best, in addition to those named, may be noted *G. alpina*, *G. Banksi*, *G. Forsteri*, *G. punicea*, *G. thelemanniana* or *Preissei*, and *G. robusta*. This last, which is well known as a foliage plant, I have never seen in flower, but in all the others the flowers are remarkable for their peculiar curved character. The uncommon *G. Forsteri* was very finely in flower in the temperate house at Kew last summer. This is a strong grower with handsome pinnate leaves, which are silvery in a young state. The flowers, which are borne in terminal cone-shaped racemes, are bright red, almost scarlet. Like most members of the genus the long style is very noticeable, being as brightly tinted as the rest of the flower.—T.

**Proposed big gardening exhibition at Regent's Park.**—It is proposed that a grand horticultural and gardening exhibition shall take place in the month of June this year under the auspices of the Royal Botanic Society. It is intended that the exhibition shall be held in the new exhibition grounds of the society, situated in the centre of their beautiful gardens in Regent's Park, the exhibition to be open for one week, or possibly longer. The proposed scheme embraces horticulture, forestry, botany, educational methods, nature study, and a special section for Colonial produce. In addition to the exhibition, lectures, conferences, and conversations are in course of arrangement. The president of the society is Major His Serene Highness the Duke of Teck. All communications respecting the gardens and exhibitions, &c., should be made to Mr. J. Bryant Sowerby, the secretary.

**Boston (Lines.) horticultural show** will be held on Wednesday and Thursday, July 20 and 21.—J. W. KILLINGWORTH AND SON, Secretaries.

**National Chrysanthemum Society.** The revised dates for the exhibitions at the Crystal Palace in 1904 are: Wednesday and Thursday, October 5 and 6; Wednesday, Thursday, and Friday, November 2, 3, and 4; Wednesday and Thursday, December 7 and 8.—RICHARD DEAN, Secretary.

**Eupatorium vernale.**—This little-known Mexican species is a most useful greenhouse plant, producing stiff, terminal corymbs of white flowers at the present time. It is easily propagated from cuttings rooted in spring, is somewhat shrubby in habit, and old plants may be grown for several years if cut back after flowering. Although quite distinct, it is sometimes met with under the name of *E. grandiflorum*, a North American species with reddish flowers, which is *Brickellia grandiflora* of "Index Kewensis."—A. O.

**A winter effect.**—One of the prettiest combinations of winter colour I have seen for some time consists of two patches of the Snowberry (*Symphoricarpos racemosus*) and the Scarlet-stemmed Dogwood (*Cornus alba*) planted close together and intermingling in places. They were planted in the ordinary course of work, without any idea of making them effective, but the result has shown what happy effects can sometimes be obtained quite accidentally. The scarlet stems of the Dogwood are strikingly shown up by the profusion of the white fruits of the Snowberry, and *vice versa*. The Snowberry, being the taller and quicker grower, should be planted in the background with the Dogwood in front, and from the middle of October until the New Year they will be found to give a cheerful bit of colour. The Snowberry begins to lose its fruits towards the end of December, but the scarlet stems of the Dogwood are still left to give a warm patch of colour. As both plants can be obtained very cheaply, anyone who has a spare corner in the shrubbery can fill it effectively at very little expense. In buying the Dogwood care should be taken to get *Cornus alba*, as it is often confounded with *C. sanguinea*, which is of no ornamental value, and only suited for cover-planting.—J. C.

**Functions of Museums.**—In the January issue of the *Popular Science Monthly*, Dr. F. A. Bather, of the British Museum, returns once more to his favourite subject—the functions of museums. After mentioning the chief functions of these institutions, the author gives some much-needed advice to the curators of local museums as to the necessity of firmness in refusing unsuitable specimens—if they do not wish the establishments under their charge to degenerate into mere curiosity shops. Small local museums are also warned that investigation is not their province—they are for education and the general public needs alone. Further, in larger establishments the investigation, the instruction, and the exhibition series must be kept apart. In the author's opinion, where museums have, as a rule, gone wrong is in exhibiting too much to the public.

**Clematis paniculata.**—This is so important a garden plant that it is a matter for wonder that it is not more generally known. Its merits may be best described by saying that it does even better for October what *C. Flammula* does for September. It much resembles *C. Flammula*, but is in every way a stouter and more vigorous grower. It may not be a plant for the cold Midlands, but anywhere south of London it is admirable. When once established the only trouble is its extreme vigour of growth. Unless it is somewhere where it may spread all round, as over an arbour or a mass of stout branching spray, it must be severely thinned in early spring or its multitude of branches become almost unmanageable. It is a native of Japan.—J.

**Character and Horticulture.**—In an address before the summer meeting of the Michigan State Horticultural Society, the Hon. Charles W. Garfield, of Grand Rapids, made an eloquent plea for the subordination of commercialism in horti-

culture. The strong tendency to measure success on all lines of work by the money standard cannot but be detrimental to the development of higher character in man; and students of sociology in all the centres of learning are also earnestly pleading against the undoubted results of this tendency in its deteriorating effects on the American people. In the evolution of character there is, perhaps, no broader field of influence than is offered by horticulture, and all the great names associated with its development have been men of marked humanity in its high and broad meaning. Notwithstanding these facts, however, it is to be noted that commercialism permeates the discussions in horticultural meetings to a serious extent, but it is a matter of congratulation to realise that the pursuit of horticulture as a calling compels the subordination of human intelligence to that higher intelligence which dominates all things, in a greater degree, perhaps, than any other line of activity, and so tends to develop the better manhood.

**The Chicago Parks.**—Extensive improvements are being planned for the Chicago parks for the coming year. Three sites for new parks have been purchased by the South Park Board at a cost of 283,000 dols. The largest of these includes 60 acres lying between 52nd and 55th Streets, and Loomis Street and Centre Avenue, and cost 183,000 dols. The other two are smaller, and were acquired at an expenditure of 50,000 dols. each. The West Park Board plans the construction of a new conservatory at Garfield Park to be the largest in the city. It will cost about 150,000 dols. The total expenditures for the West Side parks for the year were 682,000 dols., the total bonded indebtedness 1,260,000 dols.—*Park and Cemetery (America)*.

**Extension of fruit cultivation.**—Under the title of "Back to the Land: Is Fruit Farming a Solution?" an interesting lecture was delivered to a large audience in the Masonic Hall, Glasgow, on the 25th ult., by Mr. J. M. Hodge, a member of the special committee on fruit culture. The lecture favoured the movement for small holdings, with especial reference to fruit growing, and some interesting details were given with regard to the extent of the acreage under fruit, especially in the Blairgowrie district. At the close of the meeting a committee was formed to consider the propriety of forming a Scottish Small Holdings Association.

**Lectures at Dover.**—At Dover a society has been formed for the purpose of arranging a series of lectures on various subjects. On the 26th ult. the subject was "Seaside Gardening," and the lecturer Mr. T. W. Sanders. There was a good attendance, chiefly ladies, who evinced much interest in the subject, following the lecturer closely through the various points touched upon. And after the lecture was concluded many of the ladies asked various questions. It would seem that the ladies of Dover take special interest in their gardens, and one of their greatest troubles during the past season has been the plague of slugs and other vermin.

**A New Primrose.**—This beautiful yellow Primrose, Buttercup, of almost the exact colour of a Buttercup, may not be a new plant, but it certainly is newly found out, and now that it has been discovered is not likely ever to return to oblivion, as it has proved itself to be a variety of sterling merit. A plant in a 6-inch pot carries hundreds of blossoms, ranging in size from three-quarters of an inch to an inch in diameter. These are borne on spikes, which stand well alone. The foliage is something like *P. obconica*, but with the whole of the bloom distributed better up and down the stem. This latter might be a trifle stronger, as when in full flower the weight of the blossoms is apt to carry it over a little. Like many other sterling novelties, this comes to the trade through the medium of W. K. Harris, of Philadelphia, who discovered its good qualities. He disposed of a stock of 5,000 plants in two months. He says that it is the best thing sent out since *Begonia Gloire de Lorraine*. It grows readily from seed and is very easy to manage, requiring no special culture.—K., in the *American Florist*.

## THE ROSE GARDEN.

### ROSES UNDER GLASS.

**G**RAFTING will now be in full swing, and most interesting and simple work it is. If no Briars are to be had established in pots young plants with stems about as thick as a lead pencil, potted two or three weeks before grafting and placed in a greenhouse, will answer admirably. The scions should be well selected, thoroughly ripe, and must fit exactly, on one side at least. A little practice will enable the operator to make the bark upon both sides fit perfectly. The form of grafting usually adopted is known as whip grafting, but with Roses it is not necessary to make a tongue or to wax over the graft. A close-fitting frame or frames with bottom-heat must be made ready for the grafts. These frames should be placed on the side stage in a sunny position. Put about 2 inches of sand or coal ashes in the bottom of the frame and thoroughly water before placing in the grafts. If this be done and the Briars are watered before grafting they will require no water for the first five or six days after grafting. Many a graft has been spoilt owing to water finding its way between stock and scion. The temperature of the frame must be kept at about 80° to 83° night and day.

Shade with scrim or thin canvas from bright sunshine. No air must be given to the frames for the first five or six days, but after this raise the frame about 1 inch twice a day for half an hour, increasing this each day until about the fourteenth day, when the lights may be left up entirely. In about three weeks the plants are placed out in the stove house, taking care that they do not touch. When small white roots are seen at the bottom of the pots the plants must be potted on, and 3-inch pots are the better size, although many pot on direct from 3-inch to 4½-inch pots. Keep plants tied to small sticks, and carefully syringe under the foliage to disperse the red spider.

### FORCED ROSES

are now in various stages, some nearly ready to cut. Where buds are seen liquid manure may be advantageously applied once or twice a week, changing the diet now and then. Sheep manure and wood ashes make a fine manure, which is, perhaps, as good as the expensive manures advertised. Cow manure and soot will make a very safe and reliable liquid. Whatever is used it is well to remember that weak doses and often are better than strong doses at long intervals.

### CLIMBING ROSES,

such as *Maréchal Niel*, where growing in borders, must receive stimulants rather liberally. Presuming such borders received a dressing of bone-meal when plants were pruned, the plants may receive liquid manure about once a week as soon as the buds are formed. Do not encourage too many buds. Many fine plants of *Maréchal Niel* have been injured beyond repair in this way.

### ROSES FOR EXHIBITION

will now need pruning, and after this is done the branches should be tied out to lay the foundation of a shapely plant. Put a string below the rim of the pot, tie the raffia to those shoots that need tying out, and secure the raffia to the string. The finest Roses will be produced from the medium-sized, well-matured wood made last season, so that if quality is desired we must not hesitate to cut back hard. Ramblers and other Roses grown in pillar form make delightful objects for the conservatory, and should be found in every establishment. Many of the strong-growing Teas, such as *Marie Van Houtte*, *Anna Olivier*, *Medea*, &c., would also make beautiful pillars of medium height, and look far more graceful than the formal tied-out plants.

There is often a desire to obtain such Roses as *Bridesmaid* and *Catherine Mermet* as climbers for the roof. They will cover a considerable space in course of time, but if desired to do so more quickly such varieties could be budded into the young wood of an established climber. By suppressing

all the shoots of the climber another season the inserted buds would start, and very soon the desired object would be gained. There is frequently a demand for Roses during May, when the indoor plants are becoming exhausted. This demand could be met by placing a number of Hybrid Perpetuals and Hybrid Teas that were potted up last autumn into cold pits at once, prune early in February, and allow the plants to come on as naturally as possible. The plants should be plunged in ashes. Keep lights off night and day, unless frost threatens. When new growths start great care is necessary so that frost does not injure the embryo buds. The growth may be accelerated by closing up about three o'clock in the afternoon, previously lightly syringing them if the sun is shining.

#### FRANCOIS CROUSSE.

MANY growers do not know what a brilliant crimson Rose this is or it would be in great request. It is described as a climber, and as such is most useful, but it will produce its handsome buds when grown as a standard or isolated as a bush or pillar. We have none too many bright-coloured climbers or strong-growing Teas and Hybrid Teas that we can afford to have one overlooked, and I should strongly advise anyone to plant this Rose on a wall or fence or bud it as a standard. Some of its handsome buds were equal to those of General Jacqueminot in shape as seen this season, and altogether an excellent opinion was formed of its merits as a novelty, apart from the decided gain it is to our brilliant coloured climbers.

PHILOMEL.

### THE WILD PINKS.

(Continued from page 69.)

**D. MONSPESSULANUS** (syn. *D. alpestris*).—One of the prettiest and most effective of the rock Pinks; it is very free-flowering and easy to grow, succeeding in any open situation, forming tufts of grassy leaves, and producing numerous branching, few-flowered stems in summer. The flowers are red in colour and unbarbed. Growing from 6 inches to 12 inches high, this plant is found in high thickets and mountain pastures of the alps of South and Eastern Europe. Introduced in 1764.

**D. PLUMARIUS** (wild Pink).—This species differs from the wild Carnation in having a much smaller flower, and in having the petals deeply cut or fringed. It is also much hardier, and is seldom grown in pots. Pinks are, indeed, generally planted in the open border without any other care than that which is usually bestowed on hardy perennials. One of the most luxuriant in growth, quickly covering large spaces; a free seed-bearer, and crossing readily. Many of those Pinks bearing all kinds of names owe their origin to this species. With glaucous foliage and branching two to five-flowered stems; the bearded flowers vary in colour from white to purple, are deeply fringed and sweet-scented. It is found in Middle and Eastern Europe. Numerous garden varieties have been derived from this species, many of great beauty, and very variable in size and colour.

**D. REQUIENII**.—A dwarf, tufted species from the Pyrenees, with slender stems 6 inches to 9 inches high and solitary small rose-coloured flowers.

**D. SQUARROSUS**.—With flowers similar to those of *D. plumarius*, but with longer calyx segments and short, stiff, recurved leaves, the whole plant about 6 inches high. Introduced from South Russia in 1817.

**D. STERNBERGI**.—Similar to *D. monspessulanus* in habit and appearance, but smaller, with rose-coloured flowers having deeply-cut petals. From the mountains of South Tyrol and Carinthia.

**D. SUPERBUS**.—This very elegant plant is remarkable for its pleasing fragrance, its fringe-like petals, and the long, slender tube of the calyx. The colour of the flowers ranges from white to purple; it commences to bloom in August, and produces a succession for a long period. A short-lived plant; it ripens seeds freely. A very old garden plant; it has been in cultivation over three centuries, and has a very wide distribution, extending over Europe and Northern Asia to China. Very variable in size and habit; the larger forms come from the latter country, a plant flowering at Kew raised from seed collected in Central China reaching a height of 3 feet, with numerous flowers in branching panicles.

**D. WALDSTEINII**.—A native of the Eastern Alps of Europe. This may be described as a small monspessulanus.

W. IRVING.

### THE AURICULA— FEBRUARY.

As the season advances the plants begin to wake up from their winter's rest. During the month many varieties will be found in a state of active growth. Watering must therefore be attended to and applied according to the requirements of the plant. It may be more freely given than at any time since October. Should any suspicion exist as to the drainage of the plant, it can be quietly knocked out of the pot and examined, set right if necessary, and carefully replaced. The surface soil around the old plants will need to be stirred with a pointed stick, and this is the time to remove all available offsets and place round the edges of 3-inch pots, keeping them shut down close in a cold frame for a fortnight or so. After stirring the old soil some fresh, sweet potting material must be added where necessary, and well cover the neck or collar of the plant. This will encourage the formation of important rootlets which may break from it, and will also be of some assistance in forming a good truss of bloom. The plan adopted by the old growers of removing an inch or so of the old soil and replacing it with very rich compost is not thought necessary nowadays.

Presuming part of the crop of last year's seed has been sown in the autumn, the remainder may now be put in, and any young seedlings showing their first rough leaves must be shifted into fresh soil to encourage active growth.

The plants may now have all the sun that can shine upon them. Air must be freely given on all safe occasions, remembering that a cold north-east wind may injure the young foliage and cause a severe check.

In case of frost frames should be well matted over, and in the Auricula house slight heat given to exclude it, for although frost might not injure the plant, it may, even at this early stage of growth, cause damage to the truss of bloom, which is now rapidly growing.

Bishop's Stortford.

W. SMITH.

### THE CACTUS DAHLIA FOR EXHIBITION.

WHERE the best possible results are looked for in the culture of the now popular Cactus Dahlias, as well as in the other sections, no time should be lost in deciding where they are to be planted and in beginning the preparation of the soil, almost the most important item. Where the depth of good soil permits, the ground should be trenched and left rough, to throw as much surface as possible open to the frost. If trenching is out

of the question, dig it as deeply as it permits. Freshly grubbed or broken land will hardly need any manure at all, the Dahlia, like the Potato, revelling in fresh land; but where the soil is poor, a good heavy layer of horse manure, not too rotten, should be spread over and dug in early in February. This being done, the ground need not receive much more attention for the present, unless it be dug over again, and a fair coat of manure or, if heavy, ashes or road sweepings dug in. Plants for planting out may be obtained either by striking cuttings or parting the old roots or tubers. For the production of the best exhibition blooms the cuttings are almost a necessity, but if simply a large bush is desired, the old roots, to which several main stems are left, are best. Naturally, the striking of the cuttings is the more tedious of the two, but the cuttings are by no means difficult to root. In the first place all the old roots should be looked over, and broken or decaying tubers cut off. If any are rotting at all badly, cut out the affected part severely, dust over the moist raw portions with dry lime, and leave the root in a dry, warm place for a night or so. If the tubers are sound and healthy, and the old stems dry and dead, as they should be if properly treated during the winter, they are ready for starting. The grower may please himself as to the manner in which the roots shall be started for cutting production; they may be bedded in, in pits or borders in the greenhouse, or placed in shallow boxes near the hot-water pipes, or, if only a very few in number, potted. Whatever the method adopted, the temperature should be not less than 55° at night.

I may as well, perhaps, say a few words on bedding in the tubers. First, the soil may be composed of any fairly good stuff which may be at hand; siftings from the heap of old potting material are very good, with which a little well-decayed manure and a good sprinkling of sifted ashes may be added; such manure as that from old Mushroom beds is best. The tubers should have the old stem cut off to within 2 inches of the collar, i.e., the live part round the base of the stem where the eyes are clustered, and any old dry soil cleaned off; bed them in, just low enough to leave the collar clear of the surface of the soil, so that the base of the cuttings may be seen later on when taking them.

If the soil be moist when used, very little water will be needed for at least ten days, and if the tubers are dry and shrivelled care will be needed to prevent their rotting instead of starting root. In cases of this sort be very sparing of water as long as they show no sign of life. If kept in a temperature from 55° to 65° at night, cuttings will be long enough to take in about four weeks, and they should be taken near but not close down to the collar, unless only two or three are wanted of a sort; the nearer the base they are taken the more easily they strike, but fewer are produced. One cutting may be inserted in a long 2½-inch pot, an important point being the compost, two parts sweet loam, one part leaf-mould, and two parts best silver sand being a suitable mixture. Fill the pots before taking the cuttings, so that they may be inserted at once when cut off the tuber and before they flag. Put a good covering of sand on the surface of the soil in the pots. As soon as potted water them thoroughly, and stand them in a partially shaded part of the greenhouse where the air is buoyant, but the base of the pot standing on some material not too dry. The chief thing to avoid is a damp, stagnant, or a hot, dry atmosphere. If the cuttings keep fresh without being saturated daily they are in a suitable place, providing the temperature is not less than 55°, or 60° if possible. When the surface sand is dry sprinkle with a fine rose on the water-can, aiming at keeping the soil moderately moist. In three weeks the cuttings should be rooted, when they may be stood in a lighter and more sunny part of the house.

In striking Dahlia cuttings avoid hot-beds of manure, propagating pits, and hand-lights. On the whole these useful helps are not conducive to success in Dahlia work, except after a careful study of what one may or may not do. Simply root them in the open house, and if they droop

dew over gently on fine mornings. When the roots reach the sides of the pot, transfer them to large 3-inch pots in a compost of three parts loam, two parts leaf-mould and old manure, and one of sand, and soon after place them out in a frame to grow on sturdily for planting out. If the best plants are desired, another shift into a 4½-inch pot may be given at the end of April or very early May, which will keep the plants in a growing state till June. The old tubers may be left undisturbed for a time yet if they are simply to be potted or planted out as old roots, and I will leave them for the present.

EXHIBITOR.

(To be continued.)

## PRIMULAS FOR WATER-SIDE PLANTING.

The finest yellow Himalayan Primula for this purpose is the Sikkim Cowslip—*Primula sikkimensis*. The wet summer of 1903 suited well this beautiful plant. Many of the flowering spikes

will probably appear in September, but if the seed has been dried it will not germinate till next spring (1905). The seed may be sown in pans, boxes, or frames, for in the open the majority of the small plants would most likely disappear altogether during the winter. Once up the seedlings rapidly grow, and should be planted in their flowering sites in June or July. The flowers of *P. sikkimensis* possess a peculiar odour which is quite unlike the fragrance of most yellow-flowered Primulas. Perhaps it may be best likened to the odour of crushed Watercress—at any rate there is a good deal of pungency about it. As seed is so plentifully produced, it is best to raise plants every year rather than to frequently divide the clump that becomes so strong when left alone.

*PRIMULA ROSEA* does not care about a soil so heavy and pasty as does the preceding. It grows very freely slightly above water level, planted in the mossy ground that is often found near running streams, and seldom occurs in the vicinity of stagnant, dirty water. *P. rosea grandiflora* has flowers of finer colouring than the type. Neither will endure the drought that would little affect the European Mountain Primroses. Colonies may be

get cut down, unless a mild season ensures their safety. Yet in spring the plants, full of flower, appear to be no worse for their misfortunes.

*PRIMULA JAPONICA* is also an excellent wet soil plant, reaching in such 2 feet or so in height. The deep crimson flowers are arranged in whorls round the stem. The variety *lilacina* is also good, while the white form is far too little seen. *Primula japonica* has not the assured hardiness of the Indian Primroses. When naturalising these Primulas it is always best first to raise the plants in a frame, and afterwards transplant during the early summer of the first year. Even one ounce of *Primula rosea* seed does not go far when sown broadcast. If bought seed it may take a year to appear, so that it is best to have it under control.

*P. IMPERIALIS* is another large-growing bog plant, but until improved it is not equal to *P. sikkimensis* for the open air. There are several other species that may also be thus grown, although they, for the most part, need more care than the preceding. A bog is often unfitted for choicer plants, for some are mere holes filled with sour soil—sour because stagnant water abounds, and there are insufficient plants to take it up. The Botanic Garden at Cambridge contains a fine example of the treatment of water and water-loving plants, and included among the latter are many strong pieces of the best Primulas. D. S. FISH.

Royal Botanic Garden, Edinburgh.

THE SIKKIM COWSLIP (*PRIMULA SIKKIMENSIS*) BY WATERSIDE.

have borne hundreds of flowers, forming tassels 4 inches across at the apices of the 30-inch stems. Some of the stems show traces of a whorled arrangement of the flowers, which is so characteristic of *P. japonica*, *P. imperialis*, and the greenhouse *P. verticillata* and others. Probably this form might become fixed and improved by careful seed saving through several generations, but this could hardly result in a form more beautiful than the one we now have. Primulas that flower in spring and ripen their seed early do not greatly suffer from drought. But *P. sikkimensis* will stand nothing of the kind. When starved the flower-stems come down in height to nearly that of the English Cowslip. It flowers during the longest days of summer, and must, to be strong, have abundant watering and good heavy soil. Grown by the waterside the growth is very robust, and the flowering stems numerous and tall. It is best in partial shade, for strong sunlight causes the stems to flag, even when the roots are moist. Although it has been stated that this fine Primula rarely seeds in this country, here and in many other places it produces an abundance. Seed should be gathered before it is quite ripe, and sown at once. The seedlings

grown in moist woods that now only shelter and moisten our native Primroses. The hue of this Himalayan Primrose is an exceptional one in a genus of plants often containing peculiar mixtures of red and purplish shades in its flowers. The flowers of *P. rosea* appear in spring and continue for months.

*P. DENTICULATA* is another Indian Primrose that requires a moist soil. In the variety *cashmiriana* the undersides of the leaves are covered with farina; the var. *alba* has very fine white flowers, while in the var. *rosea* they are purplish rose. It is a mistake to raise imported seed of this plant, as this produces plants that are not equal to the above and other varieties grown in this country. All forms have a rounded head of blossom at the top of their stems. In the best varieties the flowers are close together in the head; in poor forms, they are loose, and of pale washy colours. Although *P. denticulata* was brought into this country more than fifty years ago, it never seems to have settled down to the English climate. As summer closes the plants are found with luxuriant foliage, that the first sharp frost totally destroys. Presently, the young, round flower heads appear in the hearts, and growing up also

## THE FLOWER GARDEN.

### SEED-SOWING NOTES.

NOW that the turn of the days has past, and the hours of light are lengthening, the hopefulness of spring is already stirring within us, and we are reminded that January begins the seed-time of the year. It is none too soon to make up our minds as to the materials we want for the season's campaign. When the seed-packets arrive to our order—be it given never so early—it will be quite time to make some of the first sowings under glass. Our present theme, however, is not so much about seed-sowing to be done in this coming springtide of 1904 as to chronicle the result of some seed-sowing that was done in the autumn of 1903. The note is made chiefly for the benefit of those who prefer to have sturdy seedlings reared without artificial heat, requiring little or no hardening off when planting time is at hand, while the gain of a season must also be taken into account.

The making of a new garden suggested the expediency of taking time by the forelock in preparation for filling empty borders in the coming year. The only regret now is that much more was not then put in hand. Seeds bought, saved, and given of many suitable kinds, however, were sown during August and September, and pricked off as they required it. At this present time, Hollyhocks, Pentstemons, Gaillardias, Ferulas, hardy Cyclamen, a new hybrid *Viola*, Pansies, and a good many more are amongst the number of capital little plants which are slowly coming on in an unheated greenhouse. This house is used for Tomatoes, planted in the raised side borders during the summer, succeeded by Chrysanthemums for cutting in the autumn, and occupied during the winter with pot Roses, bulbs coming on, and odds and ends, such as the seedlings of the hardy perennials just mentioned, all of which are the better for the shelter of glass, but need no artificial heat. No more useful type of glass structure can be added to the ordinary country house garden, especially in the interest of the working amateur of the family, for, as a rule, the gardener is not unwilling to relinquish his share in it as soon as the Tomatoes are over.

The middle to the end of January finds us fairly well to the fore in our preparations for the planting season. Flowers in pots are not altogether omitted, for, besides bulbs, Sweet Peas sown in July will come into bloom with the first blush of spring, and

the early Forget-me-not (*Myosotis disitiflora*) is beginning to open its flowers. In this latter respect, however, with more forethought much more might have been done.

Let it be urged, then, that spring, though it may be the chief, is not the only sowing time. And, should the retort be made that the advice comes a day too late for the fair, yet there is a good and valid reason why it should be given now besides the obvious one that the subject is uppermost in one's mind at the moment, viz., in order that we may reserve a portion of the spring seeds, so that they may be at hand to make the experiment in the autumn.

It is better still, no doubt, to procure freshly ripened seeds, but this is not always practicable. And, lest we forget to take advantage of such reserves when August does come, it is not a bad plan to insert—after the obliging custom of a bank at the approaching end of its cheque-books—a reminding fly-leaf in the garden diary which all good working amateurs keep, to the effect that in July we must look up our seeds for the autumn sowing; in fact, the shortest day and the longest day may both be taken as flying signals to warn us that there is this special garden work ahead, for which the time has come to make due preparation. This cap, of course, will not suit all heads, but haply it may fit one here and there of those who do not find it necessary to leave home during those two most uncomfortable months for travelling.

uncomfortable months for travelling.  
K. L. D.

### CLASSIFICATION OF SWEET PEAS.

IN THE GARDEN of the 23rd ult., you have given some very useful information about Sweet Peas. At the end of your report of the National Sweet Pea Society's audit, you give a classification of Sweet Peas made out by Mr. Hugh Aldersey of Chester. This list, although a very fair one, was criticised very much at the meeting of the National Sweet Pea Society by myself and others, and it was decided that it would be best left out of the annual report. I have made Sweet Peas a very great study for some years, and have written a little work giving the description of every known variety, and with your kind permission I should like to give your readers what I consider a better classification than that by Mr. Aldersey. This you will find enclosed, and with your kind permission also I will explain why I think this list is better for the general grower than that of Mr. Aldersey.

You will see in the class for whites I am of opinion that Dorothy Eckford is best. There is, and always has been, a great diversity of opinion as to which is the best Pea, Sadie or Blanche Burpee. I always give the preference to Blanche, because it has a more upright standard, whereas Sadie slopes too much to please me. Mr. Aldersey gives Emily Henderson as fourth. I really do not think we want more than three of any one shade of colour, but if I were to put a fourth I should give Mont Blanc in preference to Emily Henderson, because it is much earlier in coming into bloom, a full fortnight before almost any other white variety. In the blush I only give one variety, and I look upon Countess of Aberdeen as quite a variety of the past, and it is very rarely seen now on the exhibition table. I see it was only once in the first prize stand, and only five times exhibited out of 990 bunches at the last National show.

The class for cream-coloured varieties I consider somewhat misleading; we have no Pea which we could call a cream-coloured flower, they are all more or less tinged with buff. Mrs. Fitzgerald I look upon as nothing better than Stella Morse, but a flower of not much account, for it was only shown twice, and then only in those collections where a large number of varieties was wanted for variety's sake. Lottie Hutchins I consider is more

BEECH IN OPEN: NATURAL GROWTH (ABOUT 100 YEARS OLD).

of a fancy than a cream. It is very much like a pale Venus, with a slight blush at the back of the standard, and somewhat flaked with pale rose. To speak of yellow Sweet Peas is, I think, most misleading. We have no such thing as a yellow Sweet Pea yet, but we are all hoping for it, and I think the first who can raise it may be sure of getting £1,000 for his labour. It would be very much better to call them pale primrose, for seen at a distance they would be more often called white than yellow. Here Mr. Aldersey gives us four varieties again, and I think Mrs. Ormsby Gore may be well left out, for it would be a difficult matter to distinguish between that and Queen Victoria, unless they were seen side by side. Pink shades we agree upon, although he places them rather differently in order of merit. I always consider Prima Donna is a much better variety than Lovely.

To put Prince of Wales, Lord Rosebery, and Mrs. Dugdale in the rose section I think is very misleading, for the two former are totally distinct in every way from the latter, and I think my classification of it as a bright rose is more suitable. When we talk of Lady Mary Currie, Miss Willmott, and Chancellor as bright rose, I think this is also misleading, for these are more of a salmon or orange-rose than bright rose; to put Lady Mary Currie before Miss Willmott I should say was altogether out of place, and I think that is confirmed by the analysis in competition, when we see Miss Willmott was shown forty-four times, and headed the list, and Lady Mary Currie was only exhibited sixteen times. To include Gorgeous, Countess of Powis, and Meteor in the orange section is, I think, radically wrong, for all these are distinct bicolors rather than selfs, having orange standard and pink wing. Gorgeous has a much more intense standard than the other two. In the crimson, or I should say dark fiery crimson, we agree, and the same with cerise or dark salmon-scarlet. We also agree in the lavender section, but when we speak of dark blue and light blue, we again differ, for I consider Captain of the Blues is more of a light blue than a dark blue, and should be classed as such; and Countess of Cadogan should stand where Captain of the Blues does in Mr. Aldersey's list. In the violet section, I cannot see why the Duke of Clarence should be included, and when I look through the list I see it has only been exhibited four times, and is, therefore, hardly worthy of a place.

To class Mrs. Walter Wright, Dorothy Tennant, and Admiration in one section, is again misleading, in my opinion Admiration being quite a light and Mrs. Walter Wright quite a dark shade. In the dark maroon, or bronze, I see Mr. Aldersey still clings to Othello, whereas all the classifications show that Black Knight should certainly come first. To call Gorgeous, Lord Kenyon, and Calypso magenta, is, I consider, another error. Gorgeous is a bicolor, having a much paler wing than standard, and is what I should look upon as an improved Calypso, or a very dark Prince Edward of York. Lord Kenyon is more of a self, after the style of Lord Rosebery or Prince of Wales, but with more magenta. We do not differ a great deal in our bicolors apart from the comments made above, nor do we in our ideas of flakes. The Duchess of Westminster that Mr. Aldersey has included as a fancy is such a poor and indifferent flower and sports so much that it is very disappointing, and is hardly worthy of classification. I see it was only shown six times, and only once in the first prize stand. I should be glad to hear if any other lovers of Sweet Peas could give us their opinion as to these two classifications. It would be most interesting now the Sweet Pea is so very popular.

### MR. SYDENHAM'S CLASSIFICATION.

*White*.—Dorothy Eckford, Blanche Burpee, Sadie Burpee, and Mont Blanc for earliness.  
*Blush*.—Duchess of Sutherland syn. Modesty.  
*Creamy Buff*.—Countess of Lathom, Venus, and Gracie Greenwood.  
*Pale Primrose*.—Hon. Mrs. Kenyon, Queen Victoria, and Mrs. Eckford.  
*Pink*.—Prima Donna, Lovely, and Hon. F. Bouverie.  
*Bright Rose*.—Mrs. Dugdale, Royal Rose, and Apple Blossom.  
*Salmon Rose*.—Miss Willmott, Lady Mary Currie, and Chancellor.  
*Deep Rosy Crimson*.—Lord Rosebery, Prince of Wales, and Her Majesty.  
*Dark Fiery Crimson*.—King Edward VII., Salopian, and Mars.  
*Cerise or Dark Salmon Scarlet*.—Coccinea.  
*Lavender*.—Lady Grisel Hamilton, Countess of Radnor, and Lady Nina Balfour.  
*Blue (Light)*.—Emily Eckford, Captain of the Blues, and Mrs. Walter Wright (lavender-blue).  
*Blue (Dark)*.—Navy Blue and Countess Cadogan.  
*Violet*.—Duke of Westminster, Captivation, and Dorothy Tennant.  
*Dark Maroon or Bronze*.—Black Knight, Stanley, and Othello.

**BICOLORS.**  
*Rose and White*.—Triumph, Blanche Ferry, and Little Dorrit.  
*Orange and Pink*.—Gorgeous and Countess of Powis.

*Carmine or Crimson and Buff.*—Jeannie Gordon and Countess Jewel.  
*Carmine or Crimson and Pink.*—Prince Edward of York, George Gordon, and Calypso.

PLAKES.  
*Light.*—Mrs. J. Chamberlain, Aurora, and Jessie Cuthbertson.  
*Dark.*—Princess of Wales and Senator.

PICOTEE.  
 Lottie Eckford, Maid of Honour, and Golden Gate, cloudy ground.

ROBERT SYDENHAM.

Tenby Street, Birmingham.

EVERGREEN HOLLIES.

(ILEX.)

**H**OLLIES, as they are commonly known in this country, are so typically evergreen that the term "evergreen" in the title of this paper may to some appear superfluous. There are, however, numerous deciduous Hollies. *Ilex* is a large genus, to which probably upwards of 200 species are now known to belong. These are scattered widely over both tropical and temperate countries, being found on almost all the great land areas of the globe. About twenty species can be grown in the average climate of Great Britain, and eight of these are true evergreen Hollies. The deciduous ones belong chiefly to the group formerly known as *Prinos*, and are shrubs notable mainly for their handsome fruits; they are not, however, much grown nowadays. The eight species mentioned are as follow: European—*Ilex Aquifolium*; Asiatic—*I. cornuta*, *I. dipyrena*, *I. latifolia*, *I. crenata*, *I. integra*, and *I. Pernyi*; American—*I. opaca*. These Hollies have little flower beauty; the flowers are small, white or greenish. Their ornamental qualities are in their foliage chiefly, but some are also beautiful in fruit.

Hollies like a rich open loam to grown in, and on poor soils are greatly benefited by mulchings of rotted manure. Transplanting, or any other operation that involves root disturbance, should be performed in autumn (say during September if the weather is suitable), or in May, during showery weather if possible.

I. CORNUTA.

This interesting and distinct Holly was first discovered by Fortune, near Shanghai, and was sent home by him to the nursery of Messrs. Standish and Co. at Bagshot now over fifty years ago. It is still an uncommon plant in English gardens, although very handsome and quite distinct from any other species. It is apparently much dwarfer than our native Holly, and I have not seen it more than 7 feet or 8 feet high, although specimens much larger than that no doubt exist, in the gardens of the south-west especially. It is not suitable for the colder parts of the Kingdom, although at Kew I have not seen it seriously injured by frost. In habit it is a compact rounded bush, which, if left unpruned, is usually broader than it is high. Its leaves are leathery in texture, of a very dark glossy green, 2 inches to 4 inches long, and somewhat rectangular in outline. The terminal portion is armed with three large spines, and there are two also at the base. Usually, but not invariably, there is a decurved spine at each side near the centre of the leaf. The number of spines therefore is usually five or seven, but curiously Lindley and Paxton show only three in a figure in the first volume of "The Flower Garden." The fruit, which is not freely produced, is round, larger than the common Holly-berry, and red. Its attractions lie in its distinct and handsome lustrous foliage and in its shapely habit.

I. CRENATA.

Owing to its slow growth this curious Japanese Holly has never been largely grown by nurserymen, consequently it is but little planted in private gardens. It is a characteristically Japanese shrub, being close in habit, much branched, somewhat rigid and small-leaved. Sargent describes it as the most abundant and widely-distributed of the evergreen Japanese Hollies. Specimens 8 feet to 10 feet high exist in this country, and under cultivation in Japan it is frequently twice as high. It is, however, usually a low dense shrub not more than 3 feet or 4 feet high. Several forms of it are in cultivation varying in size of leaf, and the larger the leaf the more open is the habit and quicker the growth. It is, however, the typical, close-habited, rigid shrub that is, I think, so interesting and desirable. In this form the leaf is narrow, lanceolate, three-quarters of an inch long, and slightly toothed; on the whole the leaf is very like that of *Pernettya mucronata*. There are, however, other forms (var. *major* is one) with leaves much larger and more oblong in outline. Professor Sargent introduced one from Japan with leaves 1½ inches long and half as much broad. There is a variegated form in cultivation also, the leaves of which are more or less specked with yellow, but it has no particular merit. This Holly flowers frequently in this country, but does not fruit freely. The fruit is black. In Japan bushes of this *Ilex* are used as subjects for topiary work, just as Yew and Box are used with us.

I. DIPYRENA.

Coming from the Himalaya, this species is one of the less hardy Hollies. It is very rarely, however, that it is injured by cold. The fine specimen in the Holly collection at Kew, now 20 feet high and 12 feet in diameter, was not injured by the great frost of February, 1895, but I was told by the late Mr. True-love, who for many years had charge of the arboretum, that it had been once killed back to the ground level. It is an evergreen tree, 40 feet or more high, with a trunk sometimes 4 feet to 5 feet in girth; this, of course, in a wild state. The leaves are of a somewhat dull green, and not so dark as those of the common Holly; they are lanceolate, 2 inches to 5 inches long, the margins armed with thin spine-like teeth. As the tree gets older these marginal spines disappear. The fruit is one-third of an inch to half an inch in diameter, globose, and red. Whilst this Holly is not to be

recommended for general planting, it is worth the notice of those who are interested in rare trees, and especially of those whose gardens are in the warmer parts of the British Isles.

*Kew.* W. J. BEAN.

(To be continued.)

TREES AND SHRUBS.

FAGUS SYLVATICA.

**O**ur native trees none is more beautiful and characteristic than the Beech. A well grown isolated specimen, but still more an isolated group of trees, is one of the most pleasing features an English park can show. It is naturally a tree of rounded shape, with wide-spreading branches; sometimes the branches touch the ground, take root there, and ultimately form new trees—a bit of natural layering. The trunk of the Beech usually smooth and of a grey silvery colour but occasionally rough or corrugated, is, in specimen trees, short in proportion to its height. Drawn up, however, by companion trees, as in the illustration, the Beech will attain to heights of 90 feet to 100 feet, sometimes as much as 120 feet, with trunks clear to half their height.

While the Beech in its indigenous state appears chiefly to affect calcareous soils, often forming pure forests there, it will thrive in

BEECH IN PLANTATION: NATURAL GROWTH (ABOUT 100 YEARS OLD).

sandy or loamy soils. At Kew, growing on sandy soil, are many fine examples. Rooting nearer the surface than such trees as Oak or Ash, the clearing away of fallen leaves from under the Beech is a particularly ill-advised proceeding, resulting in enfeebled growth and thin foliage, even premature decay. On poor soils, indeed, the reverse process of occasionally mulching the roots with decayed leaves is to be recommended, especially in the case of isolated trees of great age.

Apart from the beauty of its trunk, the Beech in winter is less picturesque in branching than the Oak or Elm. It attains its greatest beauty, to my mind, in early June, when the young leaves have almost or quite reached their full size, but still retain that beautiful shade of pale shining green which is not quite like that of any other tree.

The Beech has sported into numerous varieties, the commonest of which is the Purple Beech. This tree, one of the most effective of our larger trees with coloured foliage, requires to be used in moderation in gardens, still more so in parks, for it does not accord well with masses of our ordinary British trees. Its foliage is very beautiful when young, being then of a pale claret colour. With age it acquires a heavy purple hue.

The best weeping varieties of the Beech, of which there are about half a dozen, are also very striking trees. None is superior to the common Weeping Beech (var. *pendula*), of which there are magnificent specimens in the British Isles, notably at the Knap Hill Nursery, in Surrey, and in the Lough Nursery, Cork. This variety forms a huge tent-like mass, the main limbs growing horizontally, while hanging from them perpendicularly are the smaller branches.

A new variety which is very highly spoken of is the Servian Beech or var. *Zlatia*, found on the mountains of Servia a few years ago. Its foliage when young is golden yellow, with all the delicacy of shade that belongs to the young foliage of the Beech in all its forms. As the season advances it turns to the ordinary green.

W. J. BEAN.

#### OLEARIA INSIGNIS.

THE various species of *Olearia* form a distinct group of Compositæ, and of the number *O. insignis* is at the same time one of the most interesting and distinct. It is a native of New Zealand, being found in the Middle Island at an elevation of 5,000 feet above sea level. It was first discovered about 1850 by Captain D. Rough, but though it has been known for so long it cannot be said to be

at all common. When growing well it makes a low, flat-headed bush, as seen in the illustration. The branches are about one-third to half an inch in diameter, and are covered with brownish felty hairs. The leaves are 4 inches to 6 inches long, elliptic, entire and thick in texture. When young they are covered on both surfaces with felty hairs like the stem, but with age much of this felt wears off the upper surface. The inflorescences are borne on long peduncles, and are axillary, or, in some cases, terminal. When axillary they come from the axils near the ends of the branches only. Each inflorescence is from 2½ inches to 3½ inches across, the ray florets being white, the dis-

temporary framework to which to train the trees till they have filled the space and formed the shape. In old days Hornbeam was the tree most used, and for a simple green alley nothing is better. Beech is also good. Several other of the smaller trees of weeping growth should be more used for this and the allied uses of training for arbours and other shelter spaces in the garden.

The Common Plane is much used on the Continent for green shelters; the trees are pollarded at about 8 feet high, and the vigorous young growths trained down horizontally to a slight framework.

It would be interesting to make a green alley

with two or, perhaps, three kinds of plants whose leaf form was of somewhat the same structure. For instance, a groundwork of Weeping Ash could soon be trained into shape, and *Wistaria* could be led to grow all over and through it. The more stiff and woody Ash would supply the eventual solid framework, and by the time the *Wistaria* was making strong growth (for it is a plant very slow to make a beginning) the whole would be well in shape, and might dispense with the framing of "carpenter's work" that is necessary for its first shaping. It would be best to plant the Ash zigzag across

OLEARIA INSIGNIS.

yellow. The peduncles, like the leaves and stems, are thickly covered with silky felt. When growing wild this *Senecio* is said to inhabit the rocky sides of rivers, the roots finding congenial conditions in fissures of rocks in which there is a deposit of rich, light soil. About London it has to be grown in a greenhouse in pots, and under these conditions it is rarely seen to advantage. In some Cornish gardens it is met with growing well, particularly in Lord Falmouth's garden, Tregothnan. Similar soil to that in which *Rhododendrons* luxuriate is most suitable for this *Olearia*.

W. DALLIMORE.

#### GREEN ALLEYS.

In the formation of green alleys there are flowering Cherries of weeping habit that would suit well for such treatment, and several other small trees of pendulous growth, such as *Laburnum*, Weeping Ash, and the large-leaved Weeping Elm. There is an important green alley at West Dean, near Chichester, of *Laburnum* only. The green alley differs from the pergola in that the pergola has solid and permanent supports, its original purpose, in addition to the giving of shade, being to support Vines. The green alley being made of stiffer and more woody growths only needs a

the path so that the main of the head of each tree might be trained across the path and down to the ground on the opposite side, when it would occupy the space between the two opposite trees.

It is important to further maintain the distinction between green alley and pergola by using in the green alley only things of a permanent and woody character; no *Roses* or *Clematis* or any other plants of which portions are apt to die or wear out. These are proper to the pergola, whose permanent substructure makes it easier to cut away and renew those of its coverings, whether structural or growing, that are liable to partial decay.

A great many delightful things may be done with these green alleys and green shelters. Much interest is already aroused in the pergola, and with it it is well to consider these other related ways of adding to the comfort and delight of our gardens. One thing, however, should be carefully considered. It should be remembered that where a path is made more important by passing under trained green growths it should have some definite reason for being so accentuated, certainly at one end, and desirably at both. It often occurs that in laying out ground the owner wishes to have a pergola, as it were, in the air, and when there is nothing to justify its

presence. It should not be put at haphazard over any part of a garden walk. If of any length, it should distinctly lead from somewhere to somewhere of importance in the garden design, and should, at least at one end, finish in some distinct full-stop, such as a well-designed summer-house or tea-house.

Another important matter is that a pergola or green alley in the usual sense should never wind or go uphill. We do not mean to say that shading coverings cannot be used in such places, but that they would want quite especial design, and it is altogether a matter of doubt if these could not be much better treated in other ways.

The circumstances of different gardens are so infinitely various that it is impossible to lay down hard rules; we can only offer general rules, and leave exceptional circumstances to be dealt with by exceptional treatment.

The illustration shows one of the most interesting features in the gardens of Hampton Court, namely, the Wych Elm Walk or Queen Mary's Bower; it is picturesque in winter with its interwoven branches, and in summer a grateful retreat from the heat of the day.

## ROUND ABOUT A GARDEN.

### THE MOST AMUSIVE GARDENING

**N**OW is the time when my favourite form of gardening—the only gardening, indeed, which I rejoice to do with my own hands—can be pursued with vigour and produces the best results per pound of energy expended. Leave the flower-beds, now in Apple-pie order—and something of mud-pie aspect—to the gardener who has marshalled underground your battalions of bulbs for their annual spring review, and betake yourself to the shrubby paths, or, better still, to the coppice or the spinney, with a large basket—a “skep” we call it in Norfolk—and a pair of shears. Everything is pushing ahead in the shelter of the Larches and the ever-greens, and now is your time to check the undesirables and give your favourites a splendid start in the race of the year.

### CHERISHED WILDINGS.

You commence operations in the grassy bay where your winding woodland path debouches like a little river upon the miniature green sea of the lawn. From here the gardener's mowing-machine sweeps always in a respectful curve, for he knows that the grass there is filled with Bee Orchids, Harebells, Dropwort, and other “field-weeds” which you cherish; and your shears are busy at once. The Winter Aconites, the Primroses, and the Polyanthus Primulas are already flowering bravely, and the Snowdrop

clusters are hastening forward; but the sticky Cleavers, the dead Nettle, and the Chervil have not been idle either, and “snip-snip-snip” go the shears, until in half an hour you have put all the weeds a month back in their growth, and in that month your flowers will have made great headway. Snipping carefully, too, for fear of cutting the green spikes of growing Daffedils, you have discovered all sorts of little woodland plants and delicate seedlings, which you had almost forgotten, and which would certainly have perished had you not come to their rescue.

### GOOD WORK FOR WINTER.

One of the best features of this form of gardening is that you can carry it on with the best effect when no other gardening is possible. If the ground is frozen hard you cannot weed the flower-beds, even if you wish; you cannot dig; and you cannot even prune for fear of injury to the cut and exposed tissues. But in shrubby or coppice gardening this injury is a point in your favour. The more you injure the undesirable weeds of the woodland by shearing them close to the ground the better chance your flowers and Ferns will have, and

if the day is cold you can select the worst “jungly” bits for your operations, when, after clearing half a dozen square yards of tangle of last year's dead luxuriance of weed and Briar, you will be quite warm enough—even if you have not to carry your own “skep” to the rubbish heap every time that it is filled.

### MAKING NEW PATHS.

You cannot have too many paths in spinney or coppice, because, wherever paths diverge, you can take the weed-plants between in flank and rear, and create new oases of selected beauty. And it is only now that you can lay out your new paths with an unfettered mind. That thin, ragged stick, which is all that stands in the way of a delightful detour round the nook where the Lilies of the Valley bloom in season, would be a flourishing young Oak tree later, and shut out the vista of potential beauty. Now you can root it up—and a few “other things” of no value—without compunction; and, lo! you have a new woodland path ready for adornment. Here, as you shear the margins close, discovering more desirable plants and seedlings than you could have hoped for, you can mark at once with labels

QUEEN MARY'S BOWER AT HAMPTON COURT: THE WYCH ELM WALK.

the spots where choice woodland plants are to be placed, and—such is the value of experience—almost always happens that these newest paths in your coppice become in a few months the most beautiful of all.

#### FAMILIAR VISTAS.

But no æsthetic comparisons diminish your joy in the old paths. Here flourish in colonies the descendants of the scraps of plants which you brought back from holiday rambles—how many years ago!—in other lands. Here you know almost exactly how every inch of ground is occupied, and the “snip-snip” of your shears is almost caressing, as you trim away the grass and trivial weed-seedlings that find slender room to stand on 3-inch tip-toe between your well-established favourites. On the main, broad paths the belt of protected plants seems clear and compact throughout, but if you neglected it for twelve months what a jungle of wild weeds and coarse grass it would become! So you work at it slowly now, inch by inch and foot by foot, and each “snip-snip” of the shears reveals some self-sown seedling flower, which would have had no chance against the coarser infants of the weeds.

#### THE PESTILENT RABBIT.

In coppice gardening you must reverse the process of the rabbit—whom, by the same token, you must not admit to your woodland garden on any excuse whatever. He is amusing and frolicsome and all that, but where there is a rabbit there is no gardening worth the name. For the rabbit goes about deliberately devouring everything which is choice and soft and delicate. Burdock with its clinging hooks, Nettle with its rank invasion and its painful sting, Elder with its stiff and unsightly luxuriance, Cleavers twisting and tangling everything into disorderly confusion—these and a few coarse umbellifers crowd the coppice where the rabbit reigns. There are a few more or less ornamental “rabbit-proof” plants, such as Rhododendron, Daphne, Barberry, Box, and Laurel,

but almost all are stiff and lumpy plants, dimly suggestive of the grouped “ever-greens” in the bare flower-beds of a sooty London “square.”

#### AISLES OF BEAUTY.

But if you reverse the rabbit's process, using your shears—not, as he uses his teeth, to destroy the delicate, but to cut out the rank, the tangled, and the unsightly, you will, in an amazingly short space of years, achieve a coppice in every respect the antithesis of the unsightly warren. Each delicate and graceful plant has, with your help, found a niche which it exactly fills, and where your original plan was happy you will have on every side tier above tier of beauty from little moss-like creeping plants which star the ground with sprinkled blossoms to the tall, flowering bushes and hardy Bamboos, which fill all the spaces below the branches of the trees with grace and greenery, splashed here and there with colour. And all that is needed to attain complete success in woodland gardening is taste and judgment at the outset and unceasing activity with shears and scissors afterwards, especially from now onwards into spring.

### TUB GARDENING.

[TO THE EDITOR OF “THE GARDEN.”]

SIR,—In answer to the queries of your correspondent “J. H. P.,” I will give our experience with tub gardening at Bessborough, County Kilkenny, where the idea was introduced several years ago by the Viscountess Duncannon, principally for the purpose of decorating the terraces during the summer and autumn months. Among the plants most suitable for this purpose are white Marguerites, which, if strong plants are prepared and planted in the tubs in good rich soil,

will give a fine display from the end of May till cut down by frosts in the autumn. These look particularly well if standing with a dark background, such as a Yew or Holly hedge. Agapanthus make splendid tub plants, also Myrtles, Camellias, Aloysias, Agaves, Geraniums (especially Ivy-leaved varieties for draping the sides of the tubs), Fuchsias, and Begonias. Cannas do very well, though looking rather stiff. Tulips (as suggested), Hyacinths and other bulbs, Wallflowers, &c., would be very nice in spring. Later, a few tubs of Arum Lilies could be tried in a sheltered position. Gladioli, the dwarf early varieties, would make a good show, but would require a groundwork of suitable dwarf plants. I have had no experience with Pæonies, but am doubtful if these would be a success in tubs.

The between-season treatment depends very much on the plants employed. The majority would require to be in a cool, light house for the winter. Plunging in leaves I do not see the necessity of. The most essential point in tub gardening is that the plants must never be neglected in the matter of watering. An occasional top-dressing is a very great help to a continual display (a little artificial manure, mixed with fine soil, is a good way of applying a stimulant), but if the plants in tubs are once allowed to flag for want of water they will never be a success, but lose colour in the foliage, cease blooming, and look altogether miserable. Regarding tins, if a great quantity are required it would save so many tubs, but all permanent plants, such as Myrtles, Agapanthus, &c., I should put straight into tubs, using tins for the softer things. Petroleum barrels sawn in two make very suitable and inexpensive tubs; they can be painted any colour, the iron bands being painted another shade if desired. If tubs were required in the winter, hardy evergreen foliage shrubs would have to be used. J. G. WESTON.

Bessborough, County Kilkenny.

[TO THE EDITOR OF “THE GARDEN.”]

SIR,—In reply to “J. H. P.,” respecting tub plants, I will endeavour to give my experience of them. In the first place, I have never found it wise to plunge any of the tubs while the plants are growing, as the roots feel the effect after the tubs are exposed in their allotted positions, and, besides, plunging has an injurious effect upon the paint or varnish as well as rotting the tubs. With regard to zinc lining it is not to be recommended, but give preference to large pots and pans made to fit stationary tubs, as it is a well-known fact that any plant grows far better in potware than in zinc. Tub filled with perfectly hardy plants should certainly have litter or any suitable material placed around them in very severe weather; they are stored away in the reserve ground to rest. As to each batch of plants having separate tubs, this will depend on the plants used; for instance, those of spring-flowering plants, consisting of biennials and bulbs, should be emptied, well cleaned, and replanted with plants to flower in summer and autumn, these being ready in their turn to receive the same class of plants by October, while other tubs contain permanent plants, which I will give below. Taking the permanent plants first:

AGAPANTHUS, before very severe weather sets in, must be removed indoors, either to a light shed or cool greenhouse, just keeping the soil moist till growth recommences. When all danger of frost is over, stand out in a good position and water copiously with both manure and clear water.

CAMELIAS treat similarly, with the exception of manure-water, giving an occasional application of diluted soot-water instead.

HYDRANGEA HORTENSIS must be protected from severe weather in any cold house or like structure till spring. In

TUB PLANTS ON THE TERRACE AT GUNNERSBURY HOUSE, A RESIDENCE OF MR. LEOPOLD DE ROTHSCHILD.

the growing season give copious supplies of clear and liquid water. This plant is a noble one when seen in good flowering condition; it flowers in summer. *H. paniculata grandiflora* to be successful with should be pruned hard back in March to one or two pairs of buds, well fed, and top-dressed. This variety will not need indoor protection. It flowers in autumn.

**ERYTHRINA** forms one of the most handsome wooded plants we have. Its coral-like flowers are greatly admired, as they last long in beauty. It needs protection from frost, and should be pruned hard back in spring and grown rapidly on.

**BRUGMANSIAS** make charming tubs. Keep them dry in the greenhouse in winter. In February prune hard back, and start removing outdoors in May.

**ALOYSIA CITRIODORA** (Sweet-scented Verbena).—This is a delightful plant for tubs, growing into perfect pyramids fully 8 feet in height. Winter it in a sheltered shed or cold house and keep dry. In spring prune the dead points back, top-dress, and start, stopping the growths when they have made six or seven pairs of leaves. Repeat this to form compactness; then let them flower in autumn if desirable. Remove outdoors in a sheltered place in early May.

**PLUMBAGO CAPENSIS** requires similar treatment; it has lavender-coloured flowers. Fuchsias, perhaps, are the finest plants grown for tubs in their season; particularly during the last two years the double variety named *Mme. Corneillon*, red and white, being compact and literally covered with bloom was a most beautiful sight. Most varieties are well worth growing. They must be kept dry during the winter and free from frost. Start in February in gentle heat, prune back, and occasionally stop them, placing them outside in May.

**LILIES** are very useful for tubs, and are of easy culture. They should be planted as soon as obtainable, placing them away from excessive wet till they have made plenty of roots. When growth appears it will then be known that root-action has taken place. Remove them out in a sheltered spot in April or May. *L. auratum* and *L. speciosum* are two excellent sorts. *Rhododendrons* and *Choisya ternata* make two capital late spring-flowering subjects. Other plants suitable where foliage alone is admired and that break the monotony of flowering tubs are *Aloes*, *Phormium tenax*, *P. t. variegatum*, *Aralia Sieboldii* (grand), *Eulalia zebrina*, *E. japonica variegata*, and *Bamboos*.

The majority of the following plants are of annual and biennial duration; thus when flowering time is past they can be thrown away and the tubs again filled with spring-flowering plants, besides evergreen ones for the winter decoration if so desired.

**CALCEOLARIA AMPLEXICAULIS** is a most charming plant grown in tubs. I have known it to grow 5 feet high and as much through. It should be staked to a certain height, then allowed to fall and grow naturally. With its sulphur-coloured flowers in profusion it forms an object never to be forgotten. Its requirements are so simple, too. Strike cuttings in autumn, inserting them in boxes, and place in a cold frame. Pot up in January, place in slight heat, repot if necessary, stake the plants, and tub as soon as the spring flowers are over.

**SWEET PEAS** for summer blooming from June onwards are wonderfully effective and pleasing. Sow four or five seeds in a 5-inch pot in February in slight heat, grow steadily on, then harden off in a cold frame. Tub them in April with due attention as to feeding and watering, keeping the fading flowers picked off to prevent seed-bearing. They will bloom uninterruptedly well into the autumn. One variety in a tub is most effective.

**CAMPANULA PYRAMIDALIS** grown into flowering sized plants in pots can always be potted in late spring, or rather tubbed, even when the spikes are throwing up. They are, indeed, noble plants for the purpose, as they will flower in July and August.

**NICOTIANA SYLVESTRIS**, where furnished tubs are required in a short time, is a first-rate plant, growing fully 5 feet high, and crowned with beautiful heads of snow-white flowers; altogether a most stately plant. Seed should be sown in heat in February, prick off, and pot on as needed. Grow

rapidly on, harden off, and tub at the end of May, placing five plants in a tub.

**TROPÆOLUMS**.—Climbing varieties such as *Brilliant*, *Firefly*, and *fulgens* are perfect masses of bloom if treated as tub plants, placing a stake for each one to ascend. Sow at the end of February, pot off, and plant in tubs in May. *Marguerites*, both white and yellow, rooted and treated the same as for *Calceolarias*, form very effective tubs.

**LOBELIA CARDINALIS** for shady parts has no equal, growing fully 5 feet high; an uncommon sight with its brilliant spikes of bloom. Keep it in cold frames in boxes through the winter. In February divide, pot up singly the strongest plants, and finally tub in May or June. When established give large quantities of water, both liquid and clear. *Salvia splendens* and its varieties form brilliant tubs if struck early in February and grown on, tubbing in May.

**CANNAS** for such work must never be forgotten, the old dark variety growing fully 6 feet high, forming a perfect mound. Store away as for *Dahlias*, start in boxes in spring, and tub in June. Foliage plants such as the golden and silver *Abutilons* make most pleasing tubs. They can be grown on in large pots for reserve plants should they be needed, also the *Ricinus*, *Begonia fuchsoides*, and *B. Ingrami*. The groundwork on some of the tubs can be filled with advantage with such plants as *Begonia semperflorens*, *Iresine*, *Sweet Alyssum*, *Salvia patens*, &c. The tubs I have chiefly used have been paraffin ones cut in half, painted to suit the taste, with extra bands attached where necessary. These answer very well. I have used just two of the "Champion" tubs, strongly recommended by you, and must say they are a beautiful and highly-finished article, strong and lasting.

GEORGE ELLWOOD.

*Swanmore Gardens, Bishop's Waltham.*

[TO THE EDITOR OF "THE GARDEN."]

SIR,—Your correspondent "J. H. P." should certainly include *Lilies* in a collection of plants for growing in tubs. *Lilies* are everybody's favourites, and they will grow as well in tubs as in the border; in fact, they will often grow better in tubs than in borders, for the preparation of soil, &c., is so much more under control. It is an important matter in the cultivation of tub plants to have thorough drainage so that superfluous water can escape. Unless this is assured all attempts are sure to end in partial or complete failure. The three *Lilies* that are most usually grown in tubs are *L. auratum*, *L. speciosum*, and *L. tigrinum*, with their varieties, but I see no reason why the list should not be extended, and such sorts as *croceum*, *Hansonii*, *Brownii*, *longiflorum*, and many more included. In fact, those whose soil will not grow some of the beautiful swamp *Lilies* of America that need moist peat for their successful culture, might do much better with them in tubs than in the border; the conditions they need could more easily be given. *L. speciosum* and *L. tigrinum* will grow well in loam and leaf-soil, with plenty of silver sand, but *L. auratum* is all the better for an admixture of peat. *L. tigrinum* and *L. speciosum* are very valuable plants for late autumn, and the latter does particularly well in the shade. The best way is to start them into growth in the spring under glass, moving them out of doors to a half-shaded position when all danger from frost is over. *Lilies* in tubs appreciate applications of liquid manure and soot water. These add colour to the leaves, as well as vigour to the flower-stems. In order to produce a good display the bulbs should be planted fairly closely together in the tubs. The best variety of *L. tigrinum* is *splendens*, while of *L. auratum* and *L. speciosum* there are numerous good ones. *Sutton's Nemesia strumosa* will make a brave show in tubs, and so will *Carnations*, *Lobelias*, and *Ivy-leaved Pelargoniums*.

To grow the latter well all the plants must not be inserted in the top of the tub, but there must be holes made in the sides to receive plants also. The result is when the plants are fully grown that the tub is a mass of flowers and foliage. At St. Fagan's, Lord Windsor's Glamorganshire seat, tub

gardening is extensively and successfully practised. The tubs of *Carnations*, *Lobelias*, and *Ivy-leaved Pelargoniums* there are very pretty objects. The plants are put in around the tubs at intervals, as well as at the top, and the result is that the latter become masses of blossom. A pleasing colour for the tubs is sage green.

A. P. H.

## GARDENING OF THE WEEK.

### THE INDOOR GARDEN.

RICHARDIA ELLIOTTIANA.

**P**ERHAPS of all the early summer-flowering plants there is none to supersede the *Golden Arum*. For quite a fortnight the flowers will last in good condition when cut and put into water. Unlike the white varieties, the golden one is deciduous, and, after a period of rest, the corms by this time should be ready for potting up and starting into growth. Plant them in pots just large enough to receive them, using a compost of equal parts leaf-soil and fibrous loam, peat being added when the loam is not sufficiently fibrous, with a little dried cow manure and coarse sand. The plant is a free grower and a gross feeder, so that liberal treatment is necessary in aiming at good culture. It is a mistake after potting to place them in a strong heat, a temperature of 50° to 55° being quite high enough in which to start them. Exercise great care in the application of water until the plants are rooting freely, but immediately they have filled their pots with roots a more liberal supply will be necessary, and occasionally a dose of liquid made from sheep manure should be given. Shift into larger pots as the plants require it, and endeavour to grow them strongly, and produce, under these circumstances, a second lot of flowers.

The stages, paths, and about the pots should frequently be moistened to create humidity, a condition in which these plants always feel at home.

LACHENALIAS.

The most generally grown of these probably is one called *tricolor*, and whilst this may in various ways be useful for decoration, it can in no way rival the bright golden one called *Nelsoni*. Where there is only a limited stock it would be advisable to grow the plants well and strengthen the bulbs by frequent applications of liquid manure; and especially will this be necessary in the case of those that are situated in baskets suspended from the roof.

CALADIUMS.

Upon the purposes for which these beautiful foliaged plants are required will depend very much the methods to be adopted in their culture. In making an effort—and this should be done at once—to start the bulbs into growth, do so by laying them on cocoanut fibre that is thinly spread over the bottom of a shallow box. The bulbs, through being kept during the winter in a dry condition, will no doubt be somewhat contracted, and require developing into their normal condition before they can either make roots or start into growth. This requires a little time, and during that period exercise care in watering, for a too liberal supply would only end in causing the bulbs to turn soft and probably rot. Create a humid atmosphere by syringing about the paths, stages, &c., and afford a more liberal supply of water only when root activity has earnestly commenced. The largest and best bulbs should be potted up together for producing large specimen plants, the smaller ones being useful to pot up singly, or four or five together, to get plants that will be excellent for table and other decorative work.

J. P. LEADBETTER

*The Gardens, Tranby Croft, Hull.*

### KITCHEN GARDEN.

EVILS OF TOO EARLY SOWING.

The past fortnight has been exceptionally mild and without rain, almost tempting one to go on

the ground and begin sowing. A great deal is said and written nowadays about sowing early, but, as far as my experience goes, I have seen little advantage in sowing till the danger from frost and cold is over. Seeds sown when the soil has been warmed a little by the sun's rays show up favourably with those that have been in the ground for weeks and become weakened by rain and cold and thinned by vermin. Instead then of starting to crop during this mild spell, take every opportunity to push on all kitchen garden work as fast as possible. Plots containing Savoys, Brussels Sprouts, or any of this tribe should be inspected, and, if the crop has been well cut, the remaining heads may be lifted and placed in any handy corner, thus permitting every plot to be dug at once. Those that cannot be so treated may have the manure carted on or near them, building it into a tidy heap until it can be dug in. Any particular crop for which the ground requires special preparation should now be seen to. Where there is a difficulty in growing Carrots, this is a good time to prepare a piece of ground for them. It is very difficult to say exactly what should be done to ensure a good crop of this vegetable. The following method has been tried with great success: Choose a border inclined to be light and sandy and with, if possible, a western exposure. After deeply trenching, wheel on several inches of sharp sand, sea sand if obtainable. Spread evenly over the whole surface, allowing it to be washed in by the rains. A good sprinkling of soot at times through the winter will benefit. It should be lightly forked in before sowing.

#### MUSHROOMS.

Horse manure must be collected daily till sufficient has been got together to form a bed. It should first be thrown loosely into a flat heap 18 inches deep till it is heated. Turn every second day. In about eight days it should be ready for forming a bed. The bed should be 3 feet in width and from 15 inches to 18 inches deep. When the bed is being made up see that the soil is made very firm. When the temperature has fallen to 80° the bed is ready for spawning. The spawn, which should be fresh and of the best quality, should be broken into pieces 1½ inches square and inserted about 8 inches apart. When this has been done give the whole a covering of good sifted turfy loam about 1 inch thick, beating very firm with the back of a spade. The house may be kept at about 60°. Give a slight damping overhead morning and evening with tepid water. THOMAS HAY.

*Hoptoun House Gardens, N.B.*

#### FLOWER GARDEN.

##### SWEET PEAS.

SEEDS may now be sown on a warm border, choosing a fine day and making the drills a few hours before sowing. Mice do not usually ferret out Sweet Pea seeds so much as they do the edible varieties, but it is as well to take some precaution, such as rolling the moistened seed in red lead or putting a thin layer of ashes over the rows and occasionally syringing them with weak paraffin and water. Where seed was sown out of doors in the autumn the soil should be kept drawn up around the young plants, and if they are at all exposed to cutting winds it will be advisable to stick a few branches of Laurel or some similar evergreen into the ground around the rows. Seedlings growing in pots or turves should be moved into frames as soon as they are well out of the soil and gradually hardened off, afterwards giving air freely to promote a sturdy growth. It will soon be necessary to give some slight support.

##### THE SHRUBBERY.

Any planting that may be contemplated should be done without delay, so that fresh roots may be formed to provide nourishment to withstand the drying winds of March. A good mulching is even more necessary than when the planting is done in the autumn. Weeds are as rampant in the shrubbery as elsewhere, and, as hoeing is out of the question, it is a good plan to turn over the top soil 2 inches or 3 inches, carefully using a flat-tined fork.

All strong growers that are encroaching should be curtailed so as to give sufficient room to the choicer shrubs. Where *Hydrangea hortensis* is grown the shoots may now be cut back to a plump bud. *Hypericum calycinum* (the St. John's Wort or Rose of Sharon) makes a capital border to the shrubbery, or if a border is too formal a few clumps here and there in the front now are very effective and useful. It flowers well under the shade of trees, and is also very effective when used as a groundwork with a few of the taller *H. moserianum* as "dot" plants. The stock may easily be increased by lifting and dividing the clumps, taking care not to break the brittle under ground stems.

##### CALCEOLARIAS.

Cuttings of the bedding *Calceolarias*, such as *C. amplexicaulis*, *C. Golden Gem*, &c., which were thickly inserted in cold pits last autumn, will now require pinching. If the stock is short the tops will quickly root if firmly inserted in sandy soil and placed in heat. The pits should be kept closed for a few days after pinching, and when growth has again commenced air should be freely admitted on fine days. That old favourite *Gazania splendens* is amenable to the same culture. It is a most useful edging plant, and looks well until very late in the autumn. One of our most admired beds last summer was composed of pink Ivy-leaf *Pelargoniums* and a broad band of *Gazania* for groundwork, and *Lobelia cardinalis* Firefly planted at intervals of 15 inches. A. C. BARTLETT.

*Pencarrow Gardens, Bodmin.*

#### THE FRUIT GARDEN.

##### PINES.

THE earliest Queens, which were started at the beginning of last month, will now be showing fruit, and require more attention. The temperature may be raised to 70° on mild nights and 80° by day. Give a little air on bright days at 80°, and a further rise of 10° may be allowed after closing. Syringe the walls and paths. The bottom-heat must be carefully watched when hard firing is necessary to see that it does not exceed 90°; if it rises above this the plants should be shaken a little to allow the heat to escape. Examine them carefully, and if dry give weak warm guano water. Do not syringe the plants overhead at this season, but maintain a moist atmosphere by damping the paths and walls several times daily, syringing the surface of the bed when the house is closed. A slightly drier atmosphere should be kept during the time the plants are in flower, and 5° lower in very cold weather.

##### SUCCESSION PINES.

These will soon require to be repotted, fresh material added to the beds, the house washed and made ready for them. The soil should be previously prepared, and should consist of good fibrous loam, and, if heavy, a little lime rubble, wood ashes, or sharp sand should be added. Add also an 8-inch pot of soot and bone-meal to each barrowful of loam. This should be well warmed through before being used. Crock the pots carefully, using those of 10 inches and 12 inches diameter for the strongest plants. Place a little soot over the crocks, and see that the plants are not dry before potting. Remove a few of the short leaves and any loose soil with a pointed stick. Only those should be potted now that have plenty of roots. They should be potted firmly, without damaging the tender rootlets. Plunge in a bottom-heat of 80°, and keep the house a little closer for a time at a temperature of 65° at night, with a 10° or 15° rise during the day. No water will be needed until they are rooted through.

##### SUCKERS.

The strongest autumn suckers which are now in 6-inch pots should be transferred into 10-inch and 12-inch pots. The latter size is better for such strong-growing varieties as Smooth Cayenne and Charlotte Rothschild. Any smaller plants may be potted into 8-inch pots. Replunge the plants 2 feet apart in the house where they are to be grown during the summer. Do not water those

potted for a fortnight, or until rooted through. Remove any suckers from the old stools as soon as large enough, so that a constant supply may be kept up, and pot in 6-inch or 7-inch pots, according to their size.

*Impney Gardens, Droitwich.*

F. JORDAN.

#### CHRYSANTHEMUMS.

COMPLETE the propagation of all varieties required for decorative purposes as speedily as possible. These will include Pompons, singles, and late-flowering sorts. They may either be rooted singly in 2½-inch pots or inserted from three to five around the outside of a 3-inch pot, using a fairly light, gritty compost, and the pots should be well drained. They will at this season quickly take root if arranged on a bed of cinder ashes in a warm pit if kept fresh by frequently spraying them over during the day. Very little air except to prevent them from damping will be needed until roots and fresh growth are made, when more should be gradually applied. In a short time remove them to a cold frame to a light, open position. The value of all kinds suitable for supplying a wealth of bloom during the short, dull days of winter can hardly be over-estimated, and many of the newer kinds introduced during the past two or three years are well worthy of a place in all collections. Particularly fine are Allman's Yellow, a fine golden yellow, and Harry Whateley, a magnificent pure white of exceptional merit, both of which have been well and largely shown this season. Many of the singles are specially well adapted for late blooming, and by stopping these they can be timed to bloom in December and early January, when flowers are so much prized. Select those of a decided colour and which carry their blooms erect. For table and general decoration these are extremely useful and pleasing, and few things at that season last better in a fresh condition even in cold rooms.

Early struck cuttings which are now occupying 2½-inch pots should be sufficiently advanced to receive a shift into a 3-inch size. The compost should be prepared some days before it is used and turned over thoroughly to mix several times. A suitable mixture for this potting will be three parts good fibrous loam of a medium texture, care being taken to retain as much of the fibre as possible, one part well-decayed leaf-soil, Oak or Beech for choice, one part old Mushroom bed manure, adding a liberal supply of coarse silver sand with a dash of finely-broken charcoal and bone-meal.

Before it is used make sure that the compost is sufficiently dry so that it does not cake together when potting. The pots and crocks should be made quite clean and well-dried, and in the case of new pots soak them before using. Sufficient fibre should be placed over the drainage to prevent the soil mixing with it, and the young plants should be well watered before shifting. This potting should be done at intervals, as the whole of the plants are seldom ready at the same time, and much harm will accrue by overpotting, especially at this season of the year. The soil should be made moderately firm about the roots, and sprinkle a little sand over the surface as each plant is potted, and ensure each being correctly labelled.

The most suitable place to enable them to recover from the slight check which they must necessarily receive is a light pit with just sufficient piping to counteract frost. Arrange them as near the glass as possible on a bed of fine cinder ashes. Sprinkle them over several times during the day when the weather is bright to prevent flagging, and about the third day thoroughly water in, using a rose watering-can and tepid water. Fill up the pots at least three times; it is essential that every particle of the soil becomes thoroughly moistened. Fire-heat should be turned off during the day, and gradually admit more air as the plants begin to make root to encourage a stout, sturdy growth, and fumigate frequently to prevent the growths becoming infested with aphids.

E. BECKETT.

*Aldenham House Gardens, Elstree.*

## ORCHIDS.

## CYPRIPEDIUM INSIGNE.

ORCHID enthusiasts are numerous around Manchester and Liverpool, and the accompanying illustration shows the interior of a house of *Cypripediums* in the gardens of one of them, S. Gratrix, Esq., West Point (gardener, Mr. George Cypher). Most of the plants in the house are forms of *Cypripedium insigne*, and such good sorts are included as *C. insigne* Harefield Hall var., *C. i. Johnsoni*, *C. i. West Point* variety, *C. i. sanderianum giganteum*, *C. i. Sanderæ*, *C. i. Chantini Lindeni*, *C. i. Dorothy*, and *C. i. Laura Kimball*. As all have been awarded first-class certificates either by the Royal Horticultural Society or by the Manchester and North of England Orchid Society, some idea may be had of the value and rarity of the contents of this house.

## AT THE SALES.

At Messrs. Protheroe and Morris' auction rooms on Friday last there was a very fine display of Orchids in flower, and there was a better demand for them than on previous occasions, though prices did not run high. During the season a good many hybrid *Cypripediums* have been sold, and any distinct novelty has commanded good prices. On Friday one was sold for £5, and another for £3; a good piece of *Lælia anceps sanderiana* made 31s.; and a good plant of *Odontoglossum Edwardii* 18s. Some fine plants of *Odontoglossum crispum* in flower were sold, the highest price being 21s. *Lycaste Skinneri* in flower made only from 4s. to 7s. each, and *Lælio-Cattleya Charlesworthi*, in bud, 11s. each. Among the new and rare Orchids, which are always offered at two o'clock, was a splendid piece of *Cypripedium leeanum clinkaberryanum*, said to be one of the finest known; it was valued at 50 guineas, but the bidding only reached 40 guineas, and we understood it was not sold. A good variety of *Cattleya Trianae* sold for 5 guineas, and a fine yellow variety of *Odontoglossum crispum* also made 5 guineas. An importation of *Cypripedium insigne* sold well, some of the best pieces

or by cutting away the leads with one or two pseudo-bulbs attached. In both cases it should be done when new roots are being emitted from last year's bulbs. If so desired, make them into specimens again; they should be so placed that all the leads point towards the rim of the receptacle, taking care properly to balance the plant. Two or three leads placed together in a 7-inch or 8-inch pot or pan make very useful plants that can be potted on without disturbance. When the method of cutting off the leads is adopted, the old plant should not be disturbed if it is in fair health. New leads will soon be made, which could be treated in the same way next season. By this means the plants are made young, and if judiciously followed up the stock will be greatly increased.

## COMPOST AND POTTING.

A good compost consists of three-fifths fibrous peat, one-fifth good chopped sphagnum, and one-fifth good leaf-soil, well mixed together with some coarse sand. Pots or pans that have no side holes are preferable to teak baskets or perforated pans. Pottling should be done rather firmly, taking care to well work the material in between the severed

CYPRIPEDIUM INSIGNE IN THE GARDENS AT WEST POINT, WHALLEY RANGE, MANCHESTER.

I WAS much interested in Mr. Mark Webster's remarks regarding the treatment of this useful Orchid. We do not often hear of manure being recommended for Orchids, yet there is little doubt that not only *Cypripediums*, but many others are greatly benefited by the judicious application of manure at certain seasons. I have heard it said that they do not get manure when growing under natural conditions, yet it seems to me that they do.

The deposit left by birds may not have much effect in the dry season, but when the rains come it is washed in among the roots, and great benefit is derived at the season when it is most needed. I have experienced similar results to those recorded by Mr. Webster, but the manures I have used have been cow manure and soot. The cow manure must be procured from a source where no disinfectants are used. I have found that *Lycaste Skinneri* and its varieties succeed well when potted in good fibrous loam used in lumps and mixed with cow manure collected from fields and thoroughly dried before using. Potted in this and given liquid manure freely while making growth, they make large pseudo-bulbs and also flower well, the flowers being much larger than under the treatment they often receive.

A. H.

making from 7s. to 10s. each. There was also a good importation of *Odontoglossum harrayanum*, the first that had been offered for about ten years. These made various prices, 16s. being about the top price. A good many went at from 5s. to 8s. each.

## THE WEEK'S WORK.

## LÆLIA ANCEPS.

THESE desirable winter-flowering Orchids, with few exceptions, will now have ceased flowering, and a strict watch for evidence of new roots should be kept if the plants require repotting or if there is a desire to propagate. They do not like being disturbed more than is absolutely necessary, so when blooming is over give an annual resurfacing or pot on as the case demands. Although good plants are seldom seen, they cannot be called difficult to grow provided they are treated right. Many dwindle away by allowing so many useless back pseudo-bulbs to remain; in fact, I consider this the principal cause of many being lost. From time to time they must be rejuvenated. This can be done either by pulling the plants carefully to pieces and removing all back pseudo-bulbs, with the exception of two behind the leading bulb,

portions, keeping the rhizome of the plant on a level with the surface. Sufficient space should be left to allow of a good top-dressing of sphagnum.

## QUARTERS.

These being such sun-loving plants, they should be given the lightest position possible in the intermediate house. During the summer they only require a very light shade during the hottest part of the day. For some time they will not require much water; those that are rooting freely will require more than the others, but it is most important that the plants should be kept dormant as long as possible. Those that start into growth late generally give more flowering bulbs. Among the best varieties are *L. a. Stella*, *L. a. Dawsoni*, *L. a. Bull's alba*, *L. a. Wad-donensis*, *L. a. schroederiana*, *L. a. hilliana*, *L. a. sanderiana*, *L. a. hollidayana* (these are white forms), *L. a. Amesiae*, *L. a. Schroderæ*, and *L. a. chamberlainiana*.

## LÆLIA JONGHEANA,

now fast developing its beautiful flowers, will require a fair amount of water and be so placed that all light and sunshine may reach the plant. The intermediate house is very suitable, and they should be suspended.

## CALANTHUS.

The deciduous kinds should be given a rest as they pass out of flower. The best place for them is a shelf in a somewhat dry house where the temperature does not fall below 55°, so that they can have the advantages of all light and sunshine. They must be left quite dry. It is immaterial whether they are kept in their pots or shaken out and placed in dry sand. If the latter is done, keep the dormant eye above the level of the sand, and see that the labels are securely attached. W. P. BOUND.

Gatton Park Gardens, Reigate.

GRADING AND PACKING  
FRUIT & VEGETABLES.

(Continued from page 80.)

MUCH could be said in favour of boxes for fruits, and, where only small sizes are employed, they may be purchased or made so cheaply that they can be included in the price of the fruit, and thus all the trouble of returning or collecting empties is avoided. Their more general use under the right conditions would assist producers to avoid overstocking the markets in seasons of heavy crops, and, by facilitating direct communication with the consumers, secure better prices. In a small way, boxes can be made at home at a cost of 1½d. to 1s. each; on a larger scale, with the use of machinery, they may be turned out at about 8s. to 50s. per 100, according to the size, and boxes costing 1d. to 6d. can always be given with the best grades of fruit usually even with profit. Many of the leading railway companies have recognised this fact, and now supply boxes of varied sizes at 1s. 6d. to 5s. per dozen, while several manufacturers also supply to large orders at very reasonable prices.

Various materials are available for packing purposes, but much the best are the several grades of wood wool now prepared, the coarsest being suitable for large packages and heavy fruits, and the finest softest samples for the choicest and ripe fruits. But wherever it is to be in contact even with Apples and Pears only the softest make should be employed; the rougher samples can be used for the bottom, or filling up at the top. All choice and delicate fruits should be encircled with bands of folded soft tissue paper having a glazed surface, which must be in contact with the fruit. This is also required to place over the top layers, but a stronger paper is used for unripe Apples or Pears.

In the actual work of packing, an even layer of wood wool is placed at the bottom of the box or basket, this being covered with a sheet of paper, and upon it the fruits to be disposed of are placed firmly. The best Plums, Pears, or dessert Apples should never be in more than two layers, and in the smallest boxes, holding one layer, they travel in the finest condition. If only one layer of fruit is made, the packing material at the bottom, and that at the top, besides the folded paper band round each fruit, will be all that is essential; but if there are two layers, they must be separated by two sheets of paper, and sufficient fine wood wool evenly spread to prevent injury to the lower fruits and form a firm bed for the upper ones to rest upon. From one dozen to four dozen of the best dessert Apples, Pears, or Plums may be so packed in one box with safety for a long journey. Peaches, Nectarines, and Apricots must always be in single layers, and demand the utmost care.

## STRAWBERRIES

can be packed in from 3lb. to 6lb. of selected fruits, but the first-named quantity is the best for the finest fruit, and the smallest of the railway boxes just holds that amount conveniently, allowing for a little packing material at the top and bottom. The same size box will hold 4lb. of best Cherries, 3lb. of Raspberries without their stalks, 3lb. Red Currants (closely packed), or 4lb. of Black Currants; but the last two may be packed in 6lb. to 12lb. lots if not too ripe; the smaller quantities are, however, preferable and safer. The finest early Strawberries should be packed in 1lb. punnets, which may be either deep or shallow, round-plaited chip punnets, or square ones (with or without handles). The

round punnets are best packed in trays with lids, and those generally employed will take six punnets. They are only used for the earliest and choicest fruits, when prices are good. Crates can be employed to hold several such trays, those large enough for six being a convenient size and weight. The square punnets are packed more closely together on sliding shelves, or in trays like the others in crates. Grapes are packed in shallow or handle-baskets, the points of the bunches towards the centre and the stalks secured to the sides or rims, the top of the basket being covered with stout paper tied round the rim, or some handle-baskets are fitted with lids. The sides and base of the baskets are sometimes padded, but they are then always covered with a soft glazed paper. The great point is to avoid rubbing the surfaces of the berries and spoiling the "bloom."

In every case, besides ensuring the security of the finest fruit, it should be displayed to the best advantage, and if the grade is uniform, as advised, this can be done quite honestly by the aid of a little coloured or white tissue paper to fold over the sides when the box is opened, and by arranging the fruits with the coloured side uppermost. The question of

## BRANDING OR LABELLING

must be considered, for where good fruit only is being dealt with, the use of the words "Seconds" and "Thirds" is apt to give rise to a misconception that is unfairly against the seller's interest. For the finest samples "Extra," "Select," or "Special" may be employed. Some mark the next grade A 1 and the next No. 1, or if the letter X is employed, three would be used for the first grade, two for the second, and one for the third. Another method is to term the best Selected No. 1, and the other grades Selected No. 2 and Selected No. 3. Something of this kind is needed to indicate that the lower qualities are not refuse but properly graded fruits. A grower should adopt a uniform system, and adhere to it, so that his brand may become known and have a market value, and every package ought to have the name of the variety and quality boldly printed on the label. Growers who intend to make a substantial business, and who deal honestly in the best produce, should have their own names on the packages. This is sometimes objected to in a market, but if a grower cannot make his business through the ordinary channels he must try fresh ones. It is best to endeavour to supply the shopkeepers, or to develop a trade with private customers, and send direct to them. The reduced rates at owner's risk on the railways, and the parcels post afford ample means for enterprising men to work up a business in small packages of choice fruits if they take the trouble to do so, either by advertising, by circulars, or by trade letters.

In packing vegetables most of the general advice already given should be serviceable; but these are disposed of in larger quantities and therefore require a different class of packages. Bags of various kinds and sizes, with large light open baskets or crates, are more extensively employed than boxes. The majority of roots are sent in bags, but the best samples of Turnips, Carrots, &c., that are bunched are sent in crates, while Radishes and small roots are sent in baskets. Green vegetables, like Cabbages, are best in crates, as also are Broccoli and Cauliflowers, but the earliest and best of the last named are often packed in flat baskets or hampers and pay for every care. The best samples for salading, such as Lettuces, are usually packed in hampers, the rougher grades in crates. Peas and Beans are packed in baskets, bushels, or half-sieves, but, as previously noted, Peas when shelled are forwarded in small boxes containing about three quarts each. Half-sieves are also used for Brussels Sprouts, pickling Onions, and other small vegetables. The earliest Rhubarb is consigned in hampers; the later often goes to market in bundles loaded direct into the vans, or packed in crates, as also is Celery. For all early and high quality vegetables shallow baskets or boxes are useful. Cucumbers, Tomatoes, Mushrooms, and many others can be conveniently sent in this way, and where periodical consignments of general vegetables are sent to private customers this is

the best method. It is necessary to pack firmly as with fruits, and where green or perishable vegetables have to travel a long distance it is desirable to gather them as shortly before packing as possible, preferably in the early morning when quite fresh, but not when drenched with rain. They should not be allowed to remain exposed to sun or wind for some hours before they are sent off, as is sometimes the case, to the obvious disadvantage of the seller. Defective or decaying samples should on no account be admitted into the packages; the uniformity so strongly recommended as regards fruits should be maintained, and it will be found that the reputation gained is a satisfactory reward for the extra care.

## CONTINENTAL NURSERIES

HOW AZALEAS ARE PREPARED FOR  
THE ENGLISH MARKET.

FORMERLY by far the largest portion of the Palms used in this country came from Belgium, and though they are now so extensively raised and grown in some of our English market nurseries, a good many still come from that country.

The growing of Palms is one of the leading features of Mr. Petrick's nursery business, but during the last ten years America has been the best market. Only a limited number of sorts are grown, *Kentia forsteriana* and *K. belmoreana* taking the lead. *Latania borbonica*, *Phoenix canariensis*, *Areca Baueri*, *Chamaerops Fortunei*, *Corypha australis*, and *Cocos weddelliana* are the principal, and they may be seen in large numbers from small seedlings to large specimens. *Raphia flabelliformis*, which is only increased by offshoots, is also grown extensively. We depend almost entirely upon the Belgian nurseries for our supply of

## THE INDIAN AZALEAS,

and the growing of them is a most important branch in Mr. Petrick's extensive nursery business, very large quantities being grown both for this country and for America, and the collection includes all the most recent sorts, some of the newer ones being of his own raising. It is rather remarkable that the system of producing these Azaleas, as adopted by the Belgian growers, has never been followed successfully by our English growers. Our variable climate, of course, has something to do with this. In Belgium they are all planted out in the open ground. The soil consists of a mixture of sandy peat and leaf-mould, but it is evident that a liberal supply of manure is added; this, I believe, is chiefly in liquid form.

It will be seen from the illustration that they are planted in beds of convenient width for watering. The men engaged in watering each use two four-gallon cans, and these are both in use at the same time (that is, they do not stand one down while they empty the other). This is by no means an easy task, and would hardly suit some of our young English gardeners.

The well-flowered plants now being sold in Covent Garden Market are all from Belgium; they usually come over about September. As the masses of roots spread considerably, there is a little difficulty in getting them into pots small enough to suit buyers, and I may point out that it is better to reduce the roots by trimming them round with a knife than to ram them too tight into the pots. A little fresh soil round the roots is more beneficial than crowding in so much of the old. They are a little inclined to lose some leaves, but this is often caused through getting heated in transit, and with those who know how to pack this does not often occur. The varieties are very numerous, and Mr. Petrick's collection is very complete, from these he selects those most suitable for market and grows them in extra large quantities. *Apollo*, *Deutsche Perle*, *Empress of India*, *Niobe*, *Simon Mardner*, *Phœbus*, *Dr. Moore*, *Mme. Van der Cruyssen*, *Paul Webber*, *Hélène Thelemann*, *Sacuntala*, *Edmond Vervaene*, *Bernard André*, *alba*, and *Pauline Mardner* are among those most in demand. I may add that although many

HOW THE GHENT AZALEAS ARE GROWN FOR THE LONDON MARKET: SCENE IN A BELGIAN NURSERY.

the fine varieties now grown are of Continental origin, we are indebted to English raisers for the first of the improved hybrids, the late Mr. Kinghorn of Richmond being the pioneer. The first of his varieties received certificates from the Royal Horticultural Society about the years 1860 to 1864. Mr. Kinghorn was soon followed by Mr. Ivery of Dorking and Messrs. Smith of Dulwich, also others including Van Houtte and M. Vervaine. We also get some from Germany, Mr. Mardoer being the raiser of some of the very best we have at the present time; and, lastly, Mr. Petrick is adding further to the list of improved varieties.

#### AZALEA MOLLIS.

This and other hardy sorts also receive attention. Large numbers of seedlings are grown, also named varieties, and the fine hybrids which are remarkable for the varied and beautiful soft tints in colour. Both the double and single varieties are well represented, all the best named varieties being grown.

Camellias are not quite so popular as formerly, but hardy hybrid Rhododendrons receive considerable attention, a large collection of the most useful sorts for flowering in pots being grown. These find much more favour for forcing than formerly, and the compact Belgian-grown plants are particularly suitable for the purpose. The standard and pyramid Sweet Bays (*Laurus nobilis*) grown in tubs, which are now so frequently seen, all come from Belgium, and Mr. Petrick has a fine stock of most perfect specimens, which are quite an attractive feature in his nursery. *Araucaria excelsa* is another plant which succeeds so well under Belgian treatment. These are grown under a protection of lath-blinds. Mr. Petrick grows his stock from cuttings, the immense quantities of plants being dwarf and well-furnished. In addition to the ordinary form, he has a fine lot of the varieties *compacta robusta* and *glauca*. The last named is a very distinct and beautiful variety.

*Eurya latifolia* is another useful plant which receives considerable attention. I am surprised that this does not find more favour; it is certainly very useful for decorations, and lasts well indoors. *Dracæna Bruantii*, *D. indivisa*, and *D. lineata* are grown in large quantities for the English and American trade. *Citrus sinensis* (the Otaheite

Orange) is also largely grown, and with a great amount of success, the plants seen in the autumn carrying a good number of fruits.

Aspidistras, both green and variegated, grow luxuriantly planted out in beds under glass. The light, well-manured soil that they are planted in is particularly favourable to the production of large leaves. Tuberous Begonias are also grown in countless numbers.

Mr. Petrick started a new nursery about twenty years ago, and has been making steady advance ever since, and now holds a most important position among the Belgian horticulturists. He is President of the Belgian Horticultural Association, member of the committee of the *Chambre Syndicale des Horticulteurs Belges*, and associated with other societies. Previous to starting in business Mr. Petrick spent some time in England, and it was while he was at the Royal Horticultural Society's Chiswick Gardens that we first knew him, and we have had the pleasure of meeting him in England many times since. He is now represented in this country by Mr. A. Hemsley.

Mr. Petrick has about twelve acres under cultivation, and sixty greenhouses, with about 75 square feet of glass. Every year about 80,000 Azalea indica are grown, of which about 15,000 are of larger sizes. The ordinary size as grown for market take three years to make good plants; they are grafted on stocks struck from cuttings. The cuttings are struck from November to February, and the grafting is done from May to September.

## BOOKS.

**England's National Flower.\***—The national flower of England—the Rose—has received the praise of a hundred authors, and pamphlet succeed pamphlet, written with the object of pressing home the claims that so beautiful a flower has upon the gardeners of all climes, hence the author has correctly described his work as "a book for all garden lovers." All who love their gardens must

\* "England's National Flower." By George Bunyard. Published by Messrs. George Bunyard and Co., Maidstone, and Simpkin, Marshall, and Co. Price 3s. 6d. net; post free, 3s. 9d.

love the Rose, too; for is it not the flower of flowers? and the garden full of Roses is the one filled with the warmest perfumes and daintiest colourings. Of late years the Rose has invaded the whole garden, and we can surely possess no flower that gives a longer season of blooming or has colours in greater variety. Mr. Bunyard first begins with a page of verses, in which Jupiter, Flora, and the Rose are concerned, and then passes to practical advice. The chapters are carefully divided, and apparently nothing has been omitted. There are notes upon "Position and Shelter," "Preparation of the Soil," "Planting and Pruning," "Bushes," "Standards," "Border Roses for a June Display," and the same for July, August, and September to November; "Massing in Beds," "Arches, Pillars, and Verandahs," "Bowers and Pergolas, Banks, Rocks, &c." for scent and for making pot-pourri, besides other phases of Rose culture. The selections of varieties have been made with commendable brevity, and it is precisely this part of the book that will probably appeal most strongly to the Rose grower, especially the beginner, who is often non-plussed when a string of varieties is printed as to the most

worthy for the garden. It is not a large book, numbering thirty-one pages, but there is a certain brightness about it wanting in many similar publications. The printing is clear, and the illustrations excellent, all having a distinct teaching value. Though the author has not attempted a serious work, there is much useful information in the book, and it should be a welcome guide to those who, in a clear and concise way, wish to know the most beautiful garden Roses available. Mr. Bunyard acknowledges his indebtedness to Mr. E. A. Bunyard for the photographs, and to Mr. Finlay Sanderson for arranging the notes and letterpress. Against each illustration quotations are given from the poets suitable to such a book. In referring to Roses for September to November, the author considers the following varieties the most certain, and in view of the forthcoming autumn exhibition of the National Rose Society this list may prove of some practical worth: Antoine Rivoire, Clara Watson, Mme. Abel Chatenay, Mme. Cadeau Ramey, Grüss an Teplitz, Lady Battersea, Liberty, Marquise Litta, Caroline Testout, Grand Duc de Luxembourg, Killarney, La France, Viscountess Folkestone, Admiral Dewey, Hélène Guillot, Perle von Godesberg, and Kaiserin Augusta Victoria. We are pleased to see that the author strongly advocates the earthing-up of Tea-scented Roses to prevent injury from winter frosts.

## THE KITCHEN GARDEN.

### PARSLEY.

PROBABLY there is no plant in the kitchen garden more in demand throughout the whole year than Parsley, and few subjects are more beautiful during summer and autumn than a bed of a good strain well grown. By far the best results are obtained by sowing the seed now in boxes and raising the plants in a gentle heat under glass. Sow thinly and gradually harden off, when the seedlings should be ready for planting out by the first week in April. Parsley is a deep-rooting subject, and revels in a rich, deeply tilled soil. The plants should be put out at a distance of 1 foot

apart all ways, and frequent applications of soot should be given. By this treatment a plentiful supply will be ensured by the middle of the summer and towards autumn. If the whole of the growth is closely cropped off it will put forth fresh leaves and become thoroughly hardened to stand ordinary winters. E. BECKETT.

## THE INDOOR GARDEN.

### WINTER-FLOWERING ACANTHADS.

**O**F late years we have certainly not made enough use of the many Acanthaceous plants that are so valuable for their winter-flowering qualities, the reason in many cases being the fact that they are often spoken of as greenhouse plants (a most elastic term), while they really need an intermediate temperature—that is, one takes the greenhouse standard as a structure for wintering Pelargoniums, Fuchsias, Heliotrope, Begonias, and many other plants that flower during the summer months. For the average run of these Acanthads a winter temperature of 55° to 65° is most suitable, though in the height of the summer they may be grown in outdoor frames without any fire-heat. Through all vicissitudes the most popular Acanthad for many years has been the delightful blue-flowered *Dædalacanthus nervosus*, far better known by the name of *Eranthemum pulchellum*. This is too well known to need any description, as its beautiful Gentine-blue flowers at once single it out when associated with other plants. A second species of *Dædalacanthus*, viz., *D. macrophyllus*, is less common than the preceding, but for all that it is a very desirable subject at this season of the year. The individual flowers are about 1½ inches long, curved in shape, and of a purplish mauve tint, the lower lobes being of a deeper hue. They are disposed in terminal branching racemes, from whence a succession of flowers is kept up for about a couple of months.

Of all the Acanthads the one that has attracted the most attention within the last two or three years is *Jacobinia chrysostephana*, not because it is a novelty, as it has been grown in this country for over thirty years, but because Messrs. Veitch have of late grown and exhibited it in such a way as to show what a really good thing it is. The rich golden orange hue of its blossoms, disposed as they are in terminal clusters, are seen to particular advantage on a dull winter's day. This plant was formerly known as *Cyrtanthera*, then as *Justicia*, before being finally relegated to *Jacobinia*. Two other well-known plants are now included in the same genus, viz., *J. giesbreghtiana*, formerly known as *Sericographis giesbreghtiana*, with long, tubular, bright crimson flowers; and *J. pauciflora*, well known as a winter-flowering plant under the name of *Libonia floribunda*. Two more species of *Jacobinia* yet remain to mention, *J. coccinea*, with terminal clusters of scarlet tubular-shaped flowers, and *J. magnifica carnea*, better known as *Justicia carnea*, whose large clusters of pink blossoms are very attractive at this season.

The genus *Justicia*, once so comprehensive, contains now but very few species, only one of which merits attention for its midwinter flowering qualities. This is *Justicia calycotricha*, known also as *Justicia flavicoma*, and *Schaueria calycotricha*. In this the flowers are, as in many of its allies, borne in terminal clusters. They are of a canary yellow colour, while the segments of the calyx are long and narrow, thus giving to a head of bloom an uncommon and fluffy appearance.

*Peristrophe speciosa*, formerly *Justicia speciosa*, is a compact plant, and for some time in the depth of winter quite a mass of bright purple blossoms; it is worth looking after by those who have to maintain a display of flowers at all seasons. A good companion to the above is *Strobilanthes isophyllus*, known at one time as *Goldfussia isophylla*, whose pale lavender flowers are borne in equal profusion to the last. The *Apelandras* are, taken altogether, among the brightest of Acanthads, but as a rule their season of blooming is not limited

to any particular period of the year. One of the best for winter blooming, or indeed for any season, is *A. nitens*, with stout, ovate, leathery leaves, olive-green on the upper surface, and purplish beneath; the flowers borne in a terminal spike, as in most of the others, are bright scarlet.

The *Eranthemums* are a very beautiful class of flowering plants, and of those that bloom during the winter may be especially mentioned *E. Andersoni*, which, as a rule, begins to flower in the autumn. It is an upright plant furnished somewhat sparingly with oblong-shaped leaves, while the flowers are borne in long, closely-packed terminal spikes. The individual flowers are very showy, being 1 inch across, and pure white, except the lower lobe or lip, which is freely blotched with rich purplish lake that is in strong contrast to the purity of the rest of the flower.

Another species now in bloom is *E. tuberculatum*, a little twiggly bush with numerous flowers, suggestive of a white *Bouvardia*; and *E. albiflorum*, whose terminal spikes are not unlike small sprays of white Lilac.

*Ruellia macrantha*, one of the largest flowers of this order, is just now very showy and valuable for decorative purposes. The flowers, which are borne singly from the axils of nearly every leaf towards the upper part of the stem, are individually somewhat trumpet-shaped, slightly curved, from 4 inches to 5 inches long, and about 3 inches across the expanded mouth. The colour is rosy purple, veined with deep crimson. The interior of the throat is much lighter than the expanded lobes, and the reticulation is there more clearly defined. A second species, *R. Herbsti*, is a pretty and interesting plant, but its ornamental qualities are not equal to those of the preceding. The flowers, which are borne in small panicles from the axils of the leaves, are much curved, about 3 inches long, and of a rosy purple hue, the expanded mouth being almost white. It was at one time known as *Dipteracanthus Herbsti*. In this review of a few Acanthads one cannot fail to be struck with the changes in nomenclature that have taken place in them from time to time. H. P.

## NOTES FROM THE MARKETS.

### COVENT GARDEN.

**A** FEW weeks ago proceedings were taken against several flower sellers for hawking without a licence. At one court fines were inflicted, and at another the magistrate refused to convict, and expressed himself surprised that the police should interfere with the flower sellers. If it was enforced that all flower sellers should have a licence, it would considerably reduce the number of flower buyers, especially in the French market. I was reminded of the above when in the French flower market on a recent Saturday. There was then quite a crowd of this class of buyers all anxious to invest a few shillings in flowers to sell in the streets at a small profit; and these sellers find most of their customers among those who could not afford to buy at the florists' shops.

The supply in the French market consists chiefly of Violets, Paper White Narcissi, Mimosa, Roses, Anemones, yellow Marguerites, and Ranunculus. There is also a good supply of "French Fern" (*Asplenium Adiantum nigrum*), also cut Myrtle, and Eucalyptus foliage. I find that this market is not quite confined to imported flowers, some English-grown produce being on sale. In the open market there is a large supply of hardy green stuff. In Ivy there is quite a variety, from the bunches of small bronzy leaves to long bundles of the ordinary trailing form; the long trails of the small-leaved are very pretty. The short, thick shoots of the Tree Ivy are also brought in large quantities. British Ferns in bunches, *Polystichum angulare*, *Polypodium vulgare*, and *Blechnum spicant* all being very plentiful.

During the past week there has been a little revival in trade. There was a considerable increase

in the supply of Daffodils, yellow doubles and singles, also bicolors; the *Polyanthus Narcissi* are also very plentiful. The pot *Chrysanthemums* are now nearly past, but the supply of cut flowers still holds out. Dutch bulbs, both in pots and cut, are now getting over-plentiful. Marguerites are still very good, but they are not seen in such large quantities as they were a few weeks ago. White flowers are very plentiful, and the Daffodils make up a good supply of yellow; but bright colours (red Tulips excepted) are very scarce. For years past so much attention has been given to all white flowers that it would now pay growers to turn their attention to colours. *Begonia Gloire de Lorraine* gives one very good colour, and if it can be put in water before it flags it lasts well. Red Roses were scarcely to be seen last week. One commission man refused an order, even though price was not limited. A week or two later may see a considerable change, but until we get the first crops of the forced General Jacqueminot red Roses will be valuable, and good English Carnations will keep up their price for some time to come yet.

*Chrysanthemums*.—We have not yet quite done with these. Mlle. Louise Charvet, which was shown by Messrs. Henderson and Sons of Elmburst-Nursery, Chessnut, and gained an award of merit at the Royal Horticultural Society's meeting on the 26th ult., deserved the honour. I had previously noted this variety in the market, where it has been selling well, making from 6s. per dozen blooms. It is not quite a new variety, having been introduced from the Continent a few years ago. I believe that it first came over from Lemoines, and we should probably have heard little of it if it had not fallen into the hands of a grower who is always on the look-out for useful sorts, and knows how to grow them when he has them. Blooms before me now are of a lovely shade, and, though they have been cut for several days, look as if they would last a long time.

*Winter Cheer*.—This is another splendid late variety which also gained an award of merit. It is a sport from Mme. Felix Perrin, and is of a very rich shade. I have seen it on the stands of Mr. Low of Uxbridge, who also has the parent in such fine form. The flowers of *Winter Cheer* are only of moderate size, but they are very attractive, and sell readily at 4s. per dozen blooms. There has been some criticism on the merits of Mme. F. Perrin and its varieties, but those who have seen them as they are sent to market cannot fail to recognise their value. *Framfield Pink*, as Mme. F. Perrin is called in the market, has no rival in the same shade of colour. *Heston White*, which has been so good in Messrs. Cragg, Harrison, and Cragg's stands, is quite as good and commands top price amongst white varieties. A. H.

## OBITUARY.

### MR. JAMES MACDONALD.

**M**ANY will hear with regret of the death of Mr. James MacDonald, which took place at 1, Stanhope Place, Edinburgh, on the 25th ult. He was for many years gardener at Murrayfield House, Edinburgh, and his length of service showed his abilities as a gardener and the esteem in which he was held by his employers. The funeral took place at North Merchiston on the 27th ult.

### MR. WILLIAM TOLMIE.

An old and respected Scottish gardener has passed away in the person of Mr. William Tolmie, Brook Street, Broughty Ferry. His death took place suddenly at the house of his son, Mr. James Tolmie, Newton Bank, St. Andrew's, on the 26th ult. Mr. Tolmie was seventy-seven years of age.

### MR. WILLIAM BROWN.

MR. WILLIAM BROWN, gardener to Dr. Bell, Mauricewood, Penicuik, Midlothian died at Mauricewood on the 26th ult.

## SOCIETIES.

## DULWICH CHRYSANTHEMUM SOCIETY.

At a special meeting of this society Mr. Percy Waterer read a most interesting and instructive paper on "Sweet Peas," in which, after dealing with the history of the flower, he referred to the great variety of colour and many other good qualities possessed by the improved forms introduced since Mr. Eckford first began to take interest in them in 1879, and a few years later Mr. Burpee. The lecturer dwelt on the necessity for a standard in form, for example, the bold, upright standard of Black Knight and the hooded standard and wings of Lady Grisell Hamilton. The double form was hardly desirable, but the Cupid and bush varieties will no doubt become popular. The importance of four flowers on a stem is over-estimated, as they are seldom evenly developed. Early planting is strongly advised, good root action being encouraged by cool weather, and deep trenching is important. It is doubtful if chag of soil is so important as is generally considered, but a change of seed is occasionally desirable. Natural manures are advised in preference to artificial, especially in a liquid state. After giving a list of desirable varieties, the lecturer suggested a selection of eighteen, consisting of Dorothy Eckford, Blanche Burpee, King Edward VII., Hon. Mrs. Kenyon, Prima Donna or Lovely, Coccinea, Navy Blue, Lady Grisell Hamilton, Black Knight, Dorothy Tennant, Miss Willmott, Lord Rosebery, Prince of Wales, Triumph, Prince Edward of York, Lord Kenyon, Salopian, and America. The lecturer proceeded to advise planting seeds in pots the first week in February, growing on and planting out after the first week in April.

The difficulty in Sweet Peas not always coming true is probably to be traced to incomplete fixing, as experiments showed that a variety often varied through difference of soil. It may also follow on the visit of a species of bee which is more prevalent now than formerly. The Sweet Pea has advantages and disadvantages in hybridising and crossing when compared with other plants, as, for instance, the Chrysanthemum. When once a variety has been fixed it is practically inexhaustible, but of course it cannot be produced by bud propagation. The lecturer carefully explained the difficult points in cultivation, and incited his hearers to endeavour, at any rate by selection, to improve the existing varieties as far as possible. Many difficulties which had presented themselves to members were satisfactorily settled, and a vote of thanks to Mr. Waterer and to the chairman, Mr. Humphreys, who was evidently an enthusiastic Sweet Pea grower, closed the proceedings.

## LEICESTER CHRYSANTHEMUM SOCIETY.

The annual meeting of this society was held at the Victoria Coffee House, on the 25th ult., when a goodly number of members attended. The seventeenth annual report proves that the society is in a flourishing condition, competition in the various classes increasing year by year. Owing to the general trade depression there was a considerable falling off in the takings at the doors during the last exhibition, which had the result of producing a deficit of £1 0s. 7d on the year's workings. But fortunately the society is in such a sound financial condition that this will scarcely be felt. To commence the year 1904 the treasurer has a substantial balance in hand of £65 19s. 6d. The newly-appointed secretary is Mr. H. P. Appleton, Countesthorpe Road, Aylestone, Leicester.

## NATIONAL CHRYSANTHEMUM SOCIETY.

The annual general meeting of this society was held on Monday last, the 1st inst., at Carr's Restaurant, Strand. Mr. Charles E. Shea presided, and there was an attendance of about fifty, including Messrs. C. Harman Payne, R. Moorman, W. Howe, T. Bevan, Norman Davis, J. McKeerchar, J. H. Whitty, H. J. Jones, R. Dean (secretary), and others.

The secretary read the notice convening the meeting, the minutes of the last general meeting, letters of regret from Mr. D. B. Crane, Mr. S. Mortimer, and Mr. Cordwell, and the following annual general report and balance sheet:

## REPORT OF THE COMMITTEE.

The committee, in presenting their annual report for 1903, do so with some degree of gratification, having regard to the altered circumstances of the society at the commencement of the year, owing to the closing of the Royal Aquarium, which entailed the necessity of seeking a new building in which to hold the society's exhibitions. Under the circumstances, some amount of depression was naturally experienced. Happily, arrangements were made with the Crystal Palace Company, whereby the three exhibitions annually held at the Royal Aquarium could take place at Sydenham. Though owing to a diminished revenue the schedule of prizes had to be modified in the direction of reduction; and though, also, the generally adverse character of the weather during the season of bloom was hostile to full development, yet the exhibitions were, on the whole, decidedly creditable to the society, the trade generously contributing miscellaneous exhibits of a high order of merit. At each exhibition, entries had unfortunately to be withdrawn, owing to the prevailing atmospheric conditions seriously affecting the permanence of the blooms; and these withdrawals materially affected the large exhibition held in November. The effect of the display made on that occasion was distinctly lessened from the fact that the space placed at the disposal of the committee was far too contracted, by reason of other exhibitions occupying a considerable portion of the building. A promise has been made that this defect will be remedied in the future. The executive of the Crystal Palace Company made the best arrangements they could under the circumstances, and your committee are under an especial debt of obligation to Mr. George Caselton, the superintendent, for his most valuable help in many ways.

The floral committee held six meetings during the year—three at the Crystal Palace and three at the Essex Hall, the

suitability of the last-named place being acknowledged by committee and exhibitors alike. Nineteen first-class certificates of merit were awarded. Arrangements have been made for continuing the meetings of the floral committee at Essex Hall in the present year. The classification committee have also held meetings, and the results of their labours will appear in the annual report. A catalogue was issued during the past year, and will be supplemented by carefully prepared lists which are to appear in the annual report. The audit of blooms shown at the November exhibitions has been prepared by Mr. A. Taylor, and will be published in the annual report, together with a census of the varieties exhibited, prepared by Mr. C. A. Young.

The annual outing of the society took place in July last, a party of 207 persons spending a delightful day at Park Place, Henley-on-Thames, by the kind permission of Mrs. Noble. The arrangements made by the secretary were much appreciated. The warmest thanks of the committee have been given to Mrs. Noble for her ready acquiescence in the requests of the committee. The annual dinner, at which the president occupied the chair, was held on November 25, a goodly number of members and friends being present. Messrs. W. Cuthbush and Son, Highgate Nurseries, generously contributed plants for the decoration of the hall, and other friends contributed fruit for dessert and flowers for the decoration of the tables. A deputation from the committee attended the exhibition of the French National Chrysanthemum Society at Lille during November, and were most hospitably entertained. The report of the deputation will appear with the schedule of prizes. The financial position of the society continues satisfactory; there is a balance in hand of £69 9s. 11d., with liabilities amounting to £5 9s. The sum of £4 7s. 6d. has been paid during 1903 on account of 1904. The reserve fund amounts to £115 15s. 11d., £100 on this being on deposit. The committee regret the loss, by death, of Mr. E. J. Bentley, who subscribed annually to this fund. Special prizes were given by the president, who continues his special first prize of £5 5s. in 1904; by Messrs. Mackenzie and Moncur, Messrs. E. Webb and Sons, Mr. G. H. Richards, Mr. W. J. Godfrey, Mr. H. J. Jones, and Mr. Robert Sydenham, all of which proved very helpful. Mr. P. Waterer's silver cups were won outright, and are now the property of the winners.

Four officers, acting as a deputation from the committee, have interviewed the general manager of the Crystal Palace Company in respect of the arrangements for 1904; the company are willing to allow space for three exhibitions, as in 1903, and there is reason to believe that the sum given for the November show will be augmented in the present year. It is also hoped that some arrangement may be come to with the Crystal Palace Company by which cheap railway and admission tickets may be provided for members and exhibitors. Should such an arrangement be made, a special circular will be issued to members and exhibitors setting forth these advantages, and giving, as far as possible, the times of departure of trains from London. The matter of entrance fees will be considered, and on the recommendation of the finance sub-committee, the sum of £50 will be added to the November schedule of prizes; a considerable number of new special prizes will also be added. It is the intention of the officers to seek the co-operation of the secretary and manager of the Crystal Palace in endeavouring to secure better facilities for the conveyance of exhibits to and from the Palace. The suggestion that an exhibition of market Chrysanthemums be held shortly before Christmas is referred to the schedule revision sub-committee for consideration and report. The present number of societies in affiliation is 125; a few have ceased to exist owing to lack of local support. The present number of members is 631, viz., 75 Fellows and 556 ordinary members, in addition to the foreign subscribers. An increase in the membership of the society is urgently needed. Your committee give their hearty thanks to Mr. C. E. Shea for accepting the office of president, for his special first prize, and for presiding at the annual dinner; also to other donors of special prizes; they also beg to acknowledge their indebtedness to the auditors, Messrs. G. J. Ingram and R. Cordwell, for auditing the accounts of the society.

Mr. Norman Davis proposed and Mr. H. J. Jones seconded the adoption of the report, which was carried unanimously. The secretary said that the Ichthemic Guano Company and Mr. Seward of Hanwell had offered special prizes, and that £12 given by the Crystal Palace Company might go as the first prize in the vase class. Mr. Taylor proposed and Mr. Foster seconded a vote of thanks to the auditors.

Messrs. Kyberg and Lake were elected scrutineers, and Mr. Lake was elected as an auditor in place of Mr. G. J. Ingram (resigned), and Mr. J. W. Moorman was elected an honorary Fellow of the society.

The secretary then read the names of six proposed new members, four paying 5s. and two paying 10s. 6d. These were all elected.

Mr. Dean proposed that the Wanstead and District Chrysanthemum Society be elected to affiliation. This was seconded and carried unanimously.

It was stated that 110 donations of 5s. had been promised for the best blooms of each of 110 different varieties. The chairman and many others thought that the judging of these would be a matter of difficulty.

There was some discussion about an exhibition of market Chrysanthemums which should be held about ten days before Christmas, and the Essex Hall was suggested as the place. Mr. Harrison said he thought such an exhibition would be excellent and welcomed by market growers. He thought it should be held earlier in December, as market growers were too busy so near Christmas.

Mr. H. J. Jones thought that early in December would be more suitable to the market growers, and finally the market growers voted December 14 to be the best date.

The following were elected to fill the fifteen vacancies on the committee. The respective number of votes is given with each candidate: W. Howe, 56; R. C. Pulling, 55; E. F. Such, 54; T. L. Turk, 52; J. T. Simpson, 51; A. E. Stubbs, 48; J. W. Moorman, 46; F. Gilks, 44; George Cuthbert, jun., 43; J. B. Linford, 43; T. Smith, 37; F. G.

Oliver, 37; G. Gover, 33; W. B. Shearn, 32; H. T. Wooderson, 30. A vote of thanks to the scrutineers was passed unanimously.

Mr. C. Harman Payne said that the National Chrysanthemum Society was to be represented on the committee of the Jubilee Exhibition of the Piedmont Horticultural Society. As already announced in THE GARDEN, the committee are particularly anxious to have exhibits of garden implements.

The usual votes of thanks terminated the meeting.

## CROYDON HORTICULTURAL SOCIETY.

AN excellent attendance of members assembled at the society's rooms, George Street, on Tuesday, the 19th ult., when the first of the new series of papers for the coming year was read by Mr. H. J. Jones, Ryecroft Nurseries, Lewisham, who took for his subject "Chrysanthemums," and for upwards of two hours he described in detail the cultivation of this popular flower. Mr. Jones is well known in the horticultural world as an expert, and his reputation as a grower was sufficient to create a lively interest in those present, who listened with great attention to his remarks, so that when his paper was concluded the applause of appreciation was unanimous. His opening remarks were on the propagation, recommending boxes for this purpose as being preferable to pots. The cuttings should be struck about December and January in slight heat, giving plenty of light; in fact, right throughout his paper the one essential thing he emphasised to secure good plants was plenty of light at all stages of growth. Passing on to the repotting, this should be done when the plants are ready, and though February and March are good months for this operation, yet no fixed dates can be laid down, but simply governed by the plants themselves. The best compost for this purpose, and also that required for each shift, he recommended, together with the different sizes of pots for each repotting. The plants should be gradually hardened off for placing outdoors about the first and second weeks in April, and the final potting off should be completed by the end of June. Due regard was paid to the drainage, and the all-important treatment of watering; also the application of stimulants by means of artificial manures were dwelt upon. The disbud operation received explicit instructions, and his concluding remarks were on the removal of plants to the houses, and antidotes to the many diseases and insect pests prevalent to these plants. From first to last he advised that to secure good blooms for decoration or exhibition the grower must give attention to the smallest details. Time would only allow a short discussion, and what questions were asked Mr. Jones replied to clearly.

Mr. W. Torney, Station Road Nurseries, Croydon, staged well-grown Primulas, and Mr. P. F. Bunyard exhibited a new plant label, the "Eclipse." Several new members were elected.

## LONDON DAHLIA UNION.

THE annual meeting of the subscribers to the union took place at the Hotel Windsor on the 26th ult., Mr. John Green, chairman of the committee, presiding over a good attendance. The minutes of the last meeting having been read, a financial statement, duly audited, was submitted by the secretary, Mr. R. Dean, which showed that the receipts from all sources amounted to £58 8s. 6d., and the expenditure to £58 6s. 1d.; but since the accounts were made up and audited an additional sum in the form of unpaid subscriptions had been received, showing a balance in hand of £2 10s. In moving the adoption of the report, the chairman congratulated the subscribers upon the very fine exhibition held at Earl's Court in September last, and said that the authorities at Earl's Court had already been approached as to arrangements for holding another exhibition there in September next, which they were desirous of taking on again. The chairman pointed out that almost without an exception the supporters of the union were members of the National Dahlia Society, and their object in holding a show was to afford an opportunity for the new Cactus Dahlias to be exhibited when they were in their best character. There was no thought or intention of antagonism to the National Dahlia Society, the president and secretary of the latter giving a cordial support to the union. The balance sheet was adopted. The secretary read a long list of names who had promised support to the exhibition in the present year. Mr. John Green was re-elected chairman and Mr. R. Dean secretary. Several special prizes were announced, and the chairman made the gratifying statement that a gentleman of position in the horticultural world had been approached with a view to becoming president of the union with much prospect of success.

The arrangements for the 1904 exhibition were left in the hands of the chairman and secretary, and the proceedings closed with a vote of thanks to the chairman for presiding and to the secretary for his services.

## LIVERPOOL HORTICULTURAL.

THE twenty-fifth annual meeting of the above was held on Saturday last at the society's office, Victoria Street, Liverpool, when Mr. T. Foster presided over a limited attendance. Mr. Harold Sadler read the annual report, which shows a considerable falling off compared with the previous year. The admissions to the spring show were, by ticket 1,707, and by payment 312; at the autumn exhibition, 1,481 by ticket and 1,299 by payment, the total being 4,889, against 6,854 for 1902. The best thanks of the association were tendered to the following for special prizes, Messrs. Thomas Davies and Co., Messrs. John Cowan and Co., Mr. H. Middlehurst, Mr. W. Rowlands, the Boundary Chemical Company, and Mr. Harold Sadler; also to the nurserymen who arranged various beautiful groups not for competition.

The statement of accounts submitted by the sub-treasurer gives the income of the spring show £32 1s. 3d., autumn show £84 1s., subscriptions £325 11s., bank interest and advertisements £20 13s. 7d. The expenditure included £173 17s. 6d. for the spring show, £265 11s. 7d. for the autumn, and £83 11s. 1d. general account, leaving a balance

in favour of the society of £195 10s. 10d., against £253 4s. 2d. at the beginning of the year. The loss is accounted for to some extent by the fact that St. George's Hall was not available for the Chrysanthemum show, which was held at the Drill Hall, Edge Lane, and although the entry of exhibits proved a second one, the attendance was much below the average. The usual donations of three and two guineas were voted to the Gardeners' Royal Benevolent Institution and the Gardeners' Orphan Fund respectively. It was arranged that the society should hold a spring and autumn exhibition during the ensuing year. The election of officers resulted as follows: President, the Right Hon. the Lord Mayor of Liverpool; treasurer, Mr. W. F. Rogers; sub-treasurer, Mr. G. Blackmore; secretary, Mr. Harold Sadler. A vote of thanks to the chairman concluded the proceedings.

#### TAYPORT HORTICULTURAL ASSOCIATION.

The annual meeting of this association was held on the 25th ult., when a satisfactory report of the finances and condition of the society was submitted. In addition to a working committee, the following office-bearers were appointed: President, Mr. James Donaldson; secretary, Mr. Alexander Melville; treasurer, Mr. A. Robertson; chairman of working committee, Mr. W. Dowie.

#### CARDIFF GARDENERS' ASSOCIATION.

A MEETING took place at the Grand Hotel on the 26th ult., Mr. H. E. Farmer in the chair, and Mr. E. W. Davy delivered a lecture entitled "Orchids." At the outset he dealt largely with the history and quotations by various authors; also upon the adventures of collectors in various parts of the world, and defining in general the natural habitat of the various species, and strongly advised cultivators to adopt those principles in this country as far as practicable. The lecture was so much appreciated that Mr. Davy was asked to repeat it at another date to be arranged for that purpose. By way of illustrations the lecturer had brought fifty hand-painted sheets representing the various types of orchids. The best thanks of the association were accorded Mr. Davy.

#### URR AND DALBEATTIE HORTICULTURAL SOCIETY.

THE annual meeting of this society was held in the Town Hall, Dalbeattie, N.B., a few days ago. Mr. A. Tait, Spottes Gardens, presided over a good attendance. Mr. Q. Aird, secretary and treasurer, presented a favourable report, which showed a moderate balance to the credit of the society. The following office-bearers were appointed: President, Rev. David Frew, Urr Manse; vice-presidents, Mr. A. Tait, The Gardens, Spottes, and Mr. John Jack, Dalbeattie; secretaries and treasurer, Mr. Q. Aird, Mr. Slater, and Mr. J. Turner. The prize list was revised, and preliminary arrangements made for the show which is to be held in Dalbeattie on August 13.

#### LOCHEE (DUNDEE) HORTICULTURAL SOCIETY.

A VERY successful social festival—an annual event—took place, under the management of this society, in the United Free Church Hall, on January 29, when there was a crowded attendance, every seat being occupied. The chair was occupied by ex-Bailie Macdonald, the president of the Dundee Horticultural Society, who fulfilled his duties admirably. The principal feature of the programme was of a musical nature, and, as the artists all acquitted themselves well, the audience enjoyed themselves thoroughly. The prospects of the society for the coming year are highly promising.

#### FELTHAM, BEDFORD, AND HANWORTH HORTICULTURAL SOCIETY.

AS a result of a course of six letters given by Mr. J. Weathers, Middlesex County Council Horticultural lecturer, the above society has been formed. The efforts have so far been very successful, and there are already fifty members.

#### SYLLABUS FOR 1904.

February 10, "Ferns," Mr. Spencer; February 17, "Primulas," Mr. Hinton; February 24, "Some Gardens I Have Visited," Mr. J. Gregory; March 1, "Carnations," Mr. Buckley; March 9, "Narcissi," Mr. Mercer; March 16, "Shrubs," Mr. Hinton; March 23, "Wild Flowers," Mr. Dobin.

## ANSWERS TO CORRESPONDENTS.

### RULES FOR CORRESPONDENTS.

**Questions and Answers.**—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" column. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 5, Southampton Street, Strand, London. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper.

**Heating conservatory** (W. S. W.).—There must be something wrong with the stove, and we fear some of the smoke escapes into the house. Do you "fire" too hard? If so that would account for the dry heat. Standing the plants upon tan, which must be kept moist, would be useful, and also frequent syringing, but that cannot be carried out at

all seasons. We should be inclined to think that you keep up too large a fire. The tan would not smell disagreeable. We should like a few more particulars about the stove—how it is fixed, and so on.

**Cyclamen culture** (WALES).—It is rather late now for sowing seed of greenhouse Cyclamen. August is the best month to do this. An exhaustive article on Cyclamen culture appeared recently in THE GARDEN, which you would do well to read.

**Melon culture** (H. WILSON).—Yes, seeds may be sown now in a warm house. Keep them near the glass and put two seeds in each small pot; if both germinate retain the stronger seedling only. When fairly well rooted in the small pots, plant out in a bed of loam upon a hot-bed. Further particulars will shortly be given in THE GARDEN.

**Shrubs for shaded ground** (K. L. M.).—The quarter of an acre of land is evidently very unfavourably placed, but the following shrubs would succeed, and in some cases flower, while the berries would make the place bright in autumn and winter, as well as provide food for the birds. As you desire Lilacs and Laburnums, you might try a few of each. If small seedling plants are put out they would in time hold their own. The Japanese and Scotch Roses associated with the wild Dog Rose and Sweet Briars would succeed well. Other useful shrubs are the Mountain Ash, Mahonia, Blackthorn, Barberry, Rubus laciniatus, Cotoneaster, Periwinkles, with Ivies.

**Rose Liberty in winter** (J. C. DAWKINS).—This splendid and brilliant Rose has now fully established itself as the best crimson for winter blooming. We may, perhaps, wish that its blossoms were larger, but much can be done to remedy this by judicious pruning. If long-stemmed, good quality flowers are desired then one must prune hard. Fewer flowers will result, but the quality will be much superior. If the variety be planted out plant rather close so as to allow of this hard pruning, or if in pots then provide more plants so that the yield is well maintained. Bone-meal is a great factor in the production of good quality of blossom in this and in most forced Roses, supplemented by liquid manure at intervals. Mildew is now so completely mastered by the use of the Sulphur Vaporiser now on the market that this one-time dreaded fungus has now no terrors. Most of the large growers of Roses for market are now using these vaporisers.

**The Butcher's Broom** (B.).—Formerly the genus *Ruscus*, to which the Butcher's Broom belongs, was more comprehensive than it is now, for the Alexandrian Laurel, so long known as *Ruscus racemosus*, and that vigorous greenhouse climber grown under the name of *Ruscus androgynus*, are now placed in separate genera. By far the best-known member of the family is the Butcher's Broom (*Ruscus aculeatus*), of which a fruiting spray was recently illustrated in THE GARDEN. It is a native of Britain, and takes its popular name from the fact that the shoots were at one time tied in bundles and used by butchers for sweeping their blocks. The foliage, or, rather, cladodes, for they are not true leaves, are dark green, and strictly evergreen, and serve admirably as a setting to the bright red berries, which in some districts are borne far more freely than in others. From the planter's point of view the great value of the Butcher's Broom is that it will thrive in shady spots and under the drip of trees, conditions that suit few other shrubs. There is a variety (*angustifolius*) in which the cladodes are narrower than in the ordinary form. *R. hypoglossum*, with oblong-shaped cladodes 3 inches to 4 inches long, is remarkable from the fact that a small leaf-like one is produced from the centre of each large cladode. The entire plant, as a rule, only attains 1 foot to 18 inches high. Like the preceding one, it will grow well in shade. *R. hypophyllum*, of much the same height as the last, and with broad cladodes, on the under sides of which the flowers are borne. The berries are red when ripe, as in the others. This is a native of the Mediterranean region, and has been long known in this country.

**Danae Laurus** (B.).—This was formerly named *Ruscus racemosus*, known as the Alexandrian Laurel, and is an ornamental little shrub. It is altogether more graceful than the Butcher's Broom, and its slender shoots reach a height of 3 feet to 4 feet. The cladodes are about a couple of inches long, and of a deep shining green. An established clump presents much the appearance of a Bamboo of small growth. It succeeds best in a partially shaded position, and looks bright throughout winter. At that season its slender shoots are valuable in a cut state for indoor decoration, under which conditions they remain fresh and bright a long time.

**Arrangement of Rose beds** (H. M.).—If two of the beds on one side are devoted to Mme. Laurette Messimy and Mme. Eugene Resal respectively, and the arch between these is to be clothed with William Allen Richardson, we think it would be a mistake to use any crimson Roses such as Fabvier and Longworth Rambler as you suggest on the opposite side of this small Rose garden. For the other arch we should most certainly employ Alister Stella Gray, which is quite the loveliest and most satisfactory variety for this purpose. As regards the two remaining beds, Jean Bach Sisley and the pink Monthly would be a beautiful combination and almost approximate in growth. Another lovely China Rose which you might use in place of the old Monthly is Mme. H. Montefiore. This grows quite as well as Mme. Laurette Messimy, and though its buds and flowers are very small they are of exquisite shape and beauty. The colour is salmon-yellow, shaded with apricot and carmine; the foliage is very pretty, and the plant a free and continuous bloomer. We ought to warn you that two Roses have been sent out under this name, and that the one we are referring to was raised by A. Bernaix of Villenarbane, near Lyons, France. The other variety distributed under this name is a Hybrid Tea of no value, sent out by Messrs. Soutper and Notting in 1890. As regards the hedge of perpetual-flowering Roses we should only use one variety. You could not do better than select Bonquet d'Or, which, taking everything into consideration, is the best of the Dijon Teas for this purpose. Next to this we should select Reine Olga de Wurtemberg,

because of the fact that it is evergreen and thus provides good shelter. It makes a good hedge, but is not so suitable as the first-named nor so free in autumn. The four arches going through this hedge should look very pretty, and we should recommend you to use François Crousse, Mme. Alfred Carriere, Dorothy Perkins, and Noella Nabonnand for these. All are perpetual except Dorothy Perkins, but this is late-flowering and of such lasting character—besides being the perfection of a climbing Rose—that you could not possibly afford to leave it out. François Crousse and Noella Nabonnand are both superb additions, and we fancy that they will prove pretty hardy. With us they have made splendid growth. We should most certainly prune the newly-planted hedge of rugosa Conrad F. Meyer very hard this spring. All strong-growing Roses intended to form pillars, hedges, climbers, &c., should be pruned very hard the first season after planting. The reason is that in transplanting these Roses it is quite impossible to prevent their roots being shortened and damaged, and before they can thoroughly recover themselves from this check they have to replace those small fibrous roots which are the ones that generally suffer. But if last season's growth is left intact this cannot take place, because the balance between root growth and stem growth is unequal. In fact, the Roses are partially disabled by producing flowers and sustaining growth disproportionate to the strength of their roots, and often enough a whole season is lost in this way, and the nurseryman who supplied the plants gets the blame.

**Shrubs for lake margin** (A. E.).—There are no flowering shrubs that we can recommend for such a position indeed, the only plants of a shrubby character likely to succeed are Willows. One of the best, from a foliage point of view, is the Rosemary-leaved, while the Cardinal Willow and the Golden Willow are remarkable for their bright-coloured bark, that of the Cardinal being red and the other yellow. All of these should be cut back each year before growth recommences, as it is the young shoots only that are so brightly coloured. Of shrubs that thrive where so situated that their roots have access to water, but at the same time are not entirely covered, may be mentioned Berberis Darwini, B. Thunbergii, Cornus alba and its varieties, Dog Roses, double-flowered Bramble, Spiraea Douglasi, Tamarisk, and Guelder Rose. You might throw up a mound clear of the water and plant the above thereon. Of herbaceous plants that would thrive in boggy soils we can recommend the Sweet Flag Water Plantain, Arundo donax, Butomus umbellatus, Caltha palustris, Iris Kempferi and pseudo-acorus, Osmunda regalis, Spiraea of sorts, particularly *S. aruncus* and *S. gigantea* (*Kmschatica*), with the stately Eulrush (*Typha latifolia*).

**Seeds in a frame** (MEDICUS).—Whilst all the various vegetable seeds you name will, if properly sown, germinate in a cold frame, most certainly quicker and better growth will result if you have a manure bed which creates some warmth. Growth, too, will be slow until the sun attains to greater strength about the end of March. Of course, something would depend also on the general condition of the weather and temperature. If you can have a manure bed, collect all the stable manure you can and put it into a heap, having first shaken out from it all the long straw. If it takes you several days, or perhaps a fortnight, to collect enough manure, you must keep the heap turned every five or six days to prevent its heating. You must also keep it fairly dry, as, if once saturated and chilled by rain, the heat will be gone entirely. The quantity of manure required would depend upon the size of your frame, and should be sufficient to build up a solid, well-trodden bed 15 inches deep in front and 18 inches behind, also be all round 6 inches broader than is the frame. A single-light frame would for that purpose need a good cartload of manure, and a double-light one, of course, much more. It is important that the heap, until enough to make a proper bed is collected, should be often turned and mixed; also, if apparently dry, be lightly moistened with water. By keeping the manure from fermenting in the heap, though it will get warm, the heat it contains is preserved, and when the bed is made up, the frame put on, and soil put into it, the heat generated is milder and far more enduring. A bed quickly made gives a violent heat; then all is soon over. If you sow your seeds on the soil you must fill up to within 6 inches of the glass. If you sow in shallow boxes or pans you can fill up the frame one-half its depth with ashea, and on those stand the boxes. In no case sow thickly, and just cover the seeds. Sow lawn grass seed in moderately dry weather early in April, well rolling it in.

### QUESTION.

**The best market Chrysanthemums.**—Will some reader of THE GARDEN kindly state which are the twelve best varieties of Chrysanthemums to grow for market?—T. S. W.

### GARDENING APPOINTMENT.

MR. HENRY LOW, late foreman under Mr. Robert Glen, gardener to J. H. N. Graham, Esq., Ladbroke House, Stirling-shire, has been appointed gardener to Lady Fowler, Braymore, Ulthapool, N.B.

### PUBLICATIONS RECEIVED.

"The Principles of Gardening in Australia," by C. Bogue-Luffman; "Laws," by Sutton and Sons; "Index Seminum in Hortis Musei Parisiensis," "Les Roses," and "Journal of the Department of Agriculture of Victoria," etc.

### CATALOGUES RECEIVED.

*Flower and Vegetable Seeds.*—Messrs. Thompson and Morgan, Ipswich.

\*\* The Yearly Subscription to THE GARDEN is: Inland, 15s.; Foreign, 17s. 6d.

[FEBRUARY 13, 1904.

## ROYAL HORTICULTURAL SOCIETY.

THE annual meeting of this society, held on Tuesday last at the Drill Hall, was a memorable one. It occurred in the centenary year, and is the forerunner of several events which will mark a great epoch in the life of this historic and flourishing society for the promotion of horticulture. The meeting was presided over by the president, Sir Trevor Lawrence, Bart., whom we never knew to be absent from these annual gatherings, and the majority of the council were present. There is little to record beyond what has already appeared in *THE GARDEN*. The meeting was peaceful, and, with the exception of the question of raising the subscription to two guineas, without incident. In 1804 the Royal Horticultural Society was established at Hatchard's, the bookseller's, in Piccadilly. The house is still standing, and it is interesting to compare the position of the society now and then, and to think of the vicissitudes through which it has passed. To-day it is strong, and gaining strength year by year, with the prospect of a new home in the Horticultural Hall next June and the opening of the garden at Wisley. And this has been accomplished by simply sticking to horticulture, making it solely a "gardening" society in the most liberal sense of the word. When a society steps outside its legitimate sphere and caters for the lighter pleasures of the people, it loses its influence and degenerates into an organisation which no one can understand. This was the source of trouble at South Kensington, and will happen again if future councils alter the policy that has been adopted with such signal success since the Rev. W. Wilks became the secretary and made Horticulture the watchword. The society never had so large a surplus as last year, when the sum was £3,641; in January of the present year subscriptions amounted to £5,757. The present financial position was clearly explained by Mr. Gurney Fowler, the treasurer. Sir Trevor Lawrence, in reply to a question asked by Mr. Elwes, stated that the invested funds of £17,500 would not be touched for the purposes of extinguishing the sum of £15,000 still required to relieve the Hall of debt, but it was hoped that before the opening day a large part of this amount would be raised.

Mr. Elwes also recommended that the Journal be charged extra to the Fellows;

the answer to this naturally was that many subscribed to the society simply for the purpose of these valuable quarterly volumes, but Sir Trevor hoped that those who were indifferent about the Journal would kindly say so, and in this way help towards reducing the expenses entailed in its production. Mr. Gurney Fowler gave the following information regarding the new Hall Fund: Donations received, £22,561; interest on temporary investments, £451; and promised subscriptions, £2,113; which made a grand total of £25,125. The sum of £12,124 has been spent, and the balance in hand is £10,888, excluding the promised subscriptions. This leaves a balance of £12,001 to meet present liabilities. The contracts were £34,780, of which £10,379 has been already paid. The balance to pay is £24,401. Towards this there is a sum of £13,001, therefore the deficit is £11,400. It is proposed to raise a loan at the bank with the investments as a security until the subscriptions come in, or if necessary get a mortgage from an insurance company to be met out of annual surplus; it is satisfactory to know that in January of this year over £1,500 was subscribed.

We mention this to make it quite clear that, although the total sum required has not been subscribed, there are strong hopes that this happy state of affairs will not be delayed many months. The Fellows should make a determined effort to collect this sum before the new Hall is opened, and relieve the council, who have worked loyally and unselfishly to mark the centenary year in a way future generations can never forget. With regard to the Wisley garden no strong appeal was made for funds, and this is wise until the new Hall has been paid for; but we may remind those who have not subscribed to the Hall—for the reason that they considered a new garden a better way of marking the centenary—that the secretary will be quite willing to receive subscriptions towards its lay-out and upkeep. Those who wanted the garden have an opportunity of giving practical effect to their desire; the garden has been *given*, but money is wanted to establish the great horticultural work we expect to see carried out in those sixty acres. Sir Trevor Lawrence said that the surrender of the Chiswick lease would realise the sum of £5,000, and this is to go to the Wisley garden expenses.

The event of the afternoon was the question of doubling the annual subscription. This would have been hotly and rightly opposed, for the good reason that country members have

few opportunities of visiting the fortnightly meetings and the large shows. An amendment was proposed by Mr. H. J. Veitch to the effect that a charge of one guinea entrance fee be made, except to Fellows paying two guineas and four guineas, and in the case of *bona-fide* gardeners and Fellows residing abroad; this was carried unanimously.

No one can grumble that an unjust change has been made in adopting the system of almost every club and society in the world. A Fellowship carries no distinction. A man who is ignorant of the commonest wild flowers may be an F.R.H.S., and to improve his faint horticultural knowledge by joining the society is worth the initial subscription, for after all we want the general public as well as the more professional element. The Royal Horticultural Society is a teaching society, and its affairs are never likely to be ruled over except by men of experience. The list of the members of the various committees shows how earnest a band of workers is guiding the society and encouraging gardening at home and abroad.

## KEW AND THE ROYAL HORTICULTURAL SOCIETY.

I OBSERVE that you state in *THE GARDEN* of the 6th inst. that "it has been whispered, though perhaps there may be no truth in it, that the formation of a scientific department at Wisley will be hotly opposed, in the belief that all work of this character should be carried on at Kew." Certainly, as far as I am concerned, and I do not know who else has a right to express an opinion in the matter, there is no truth in it. And you are only stating a plain fact when you "cannot think that a scientific department at Wisley will cause the slightest jealousy at Kew."

There never was a time when as a nation we stood more in need of the aid which science can give to industrial effort. The intensive cultivation of the land has fallen behind an attainable standard. The policy of Kew, working under the Board of Agriculture and Fisheries, far from attempting to centralise research in one establishment, or even in the neighbourhood of London, has consistently aimed at encouraging it in as many centres as possible.

Personally, I should like to see a horticultural Rothamsted. The munificence of Sir John Lawes endowed agriculture with £100,000; where shall we find the man who will do something comparable for horticulture?

Having stated my official views, I may be permitted to speak in my private capacity as

one deeply interested in the welfare of the Royal Horticultural Society, to which three generations of my family have supplied Fellows. I have never wavered in the opinion that the provision of a suitable hall, offices, and library is absolutely indispensable to the society's continued existence and prosperity. In my judgment it would be wise to dispose of that before embarking on a new enterprise. If the society is to create "a scientific department" it must be organised on an efficient basis, and animated by a far more vigorous and intelligent spirit than has for many years been pursued at Chiswick. The suggestion that has been made of providing a log hut with a microscope and an expert at £300 is hopelessly inadequate. I must also be permitted to have my own opinion as to whether Wisley from position and soil is the place best suited for the proposed horticultural station.

*Kew.* W. T. THISELTON-DYER.

## RIVIERA NOTES.

OLD-FASHIONED gardeners like myself are apt to rebel against the constant changes in the names of plants, so often as it seems without adequate reason. Why, I wonder, is that fine shrub or tree *Senecio Ghiesbreghtii* or *arborescens* now called *grandifolius* when there is already and for many years the well-known *S. macrophyllus*, now distinguished only by a difference in tongue and not in name? To those accustomed to see this grand and massive tree-like shrub growing in the open and glowing with enormous flower-heads it is astonishing to hear it is best grown annually from cuttings! Like the *Poinsettia*, it does make a decent show with one head on one stem, but I hope those who have room will plant it out and see what it can then do. I think no one will regret it, and the long continuance of subsidiary flower-heads is another reason for so doing.

The early *Narcissus intermedius* (*Tazetta*) is always delightful at this season. I suppose it must have some of the tenderness of the Paper White *Narcissus* in its constitution, or it must long ago have been in every English garden, where it would flower as early as the ever-welcome *N. pallidus præcox*, which loves the shade and shelter of Bamboo clumps as much as *N. intermedius* loves a dry, sunny bank among the Aloe suckers. *N. intermedius*, however, is quite able to take care of itself anywhere, while the dainty and delicate *N. pallidus præcox* will only grow where it has shade, shelter, and undisturbed possession of its own particular nook. The very plant for the careful amateur.

What a curious similarity there is sometimes between different plants was brought to my notice the other day by a visitor, who exclaimed on seeing a bush of the pretty Cape shrub *Diplopappus fruticosus*, now in full flower, "What a delightful *Michaelmas Daisy* bush you have there, and why don't we grow it in England?" The reason is not far to seek, for pretty as it is, it is no prettier than most *Asters*, and it requires a drier air and warmer climate than England affords, while as a pot plant it is apt to be straggly, as is also the bright yellow *Senecio pinnifolius*, which flowers with it and enjoys the same conditions.

*Lachenalia pendula aureliana* is certainly a very fine thing, and should be taken care of by those who possess it. A clump or two of it among white *Primulas* is a thing to remark on wherever it may be, and its habit of flowering in January before the very earliest *Tulips* are

out makes its colouring the more noticeable. It is quite unaffected by any bad weather here during the last two years, and seems a plant really worth growing.

Each winter I think I admire more and more the continual flowering of *Illicium anisatum*. Its starry heads of slightly fragrant white flowers, its bright Apple-green leaves, with red-barked, arching stems, make it most attractive in a damp and shaded corner, where it is most at its ease. Because it takes some years before it shows its beauty it is but little grown. Its straggling stems need some support when weighed down with the clusters of flower. Perhaps it might do well on a wall in England. Can anyone tell of one that has succeeded?

*Nice.*

E. H. WOODALL.

## NOTES OF THE WEEK.

### FORTHCOMING EVENTS.

February 23.—Royal Horticultural Society's Drill Hall Meeting, 12 noon.

March 8.—Royal Horticultural Society's Drill Hall Meeting.

March 9.—East Anglian Horticultural Club Meeting.

**The Royal Horticultural Society and the special societies.**—In your interesting leading article, on page 88, you say: "We are sorry to find that Baron Schröder has been compelled to issue a second appeal on behalf of the Hall fund. . . . The new Hall will prove a boon to the many special societies that are constantly appealing to the Horticultural Club for the use of its rooms at the Hotel Windsor." There is an intimate association in the train of thought that prompted these two paragraphs. Is the Royal Horticultural Society quite sympathetic towards the special societies? If so, how comes it that it has recently pressed such onerous conditions upon the National Dahlia Society as to drive it back to the Crystal Palace? It can scarcely be doubted that this unhappy event—small in itself, perhaps—has had a share in checking the flow of subscriptions to the Hall fund. The special societies are too numerous and too strong to be treated in a cavalier way. They would be loyal to the great parent society, and a strong bulwark of support to it, if they were sympathetically dealt with. Let me add, sir, a word of grateful acknowledgment of the kindness of the committee of the Horticultural Club in connexion with the use of the club room at the Hotel Windsor for the committee meetings of the various societies.—WALTER P. WRIGHT, *Secretary, National Potato Society.*

"Nous n'irons plus au bois, les lauriers sont coupés."

Then come away! The woods are cut;

There is no beauty now;

No fragile flower on trembling stem,

No swinging branch in sunset glow.

The ships that started fresh and fair

Come home bestript of sail and mast;

The bluebell ghosts, just here and there,

Bespeak of springtime glory past.

Then come away! We will not spoil

The memory of what has been,

But onward patiently will toil

To other woods, still fresh and green.

M. C. D.

**Proposed excursion to Shrewsbury horticultural fete.**—A number of horticulturists and others interested living in Scotland having expressed a wish to visit this popular show, negotiations have been opened with the railway companies for such an excursion, which will be organised if sufficient support is promised. Excursionists might leave Edinburgh late on Tuesday night, and return from Shrewsbury on Wednesday night, or have an option to remain a day or two longer. Intimation, or application for further particulars, should be made to the undersigned, and it will greatly facilitate arrangements

if early intimation can be given. Such intimation does not bind anyone to go if, later, circumstances should prove unsuitable.—P. MURRAY THOMSON, *Secretary and Treasurer, Royal Caledonian Horticultural Society, 5, York Place, Edinburgh*; PETER LONEY, *Secretary, Scottish Horticultural Association, 6, Carlton Street, Edinburgh.*

**Royal Horticultural Society.**—We understand that an assistant secretary has been appointed at a salary of £200 a year, and we think it is quite time the present secretary, the Rev. W. Wilks, received substantial assistance in his work, which has increased greatly of late years. Editing the "Journal" itself is a serious burden.

**Forestry in the United Kingdom.**—On Thursday, the 25th inst., at 8 p.m., Professor Schlich will give a lecture in the Carpenters' Hall, London Wall, on "The Forestry Problem in the United Kingdom." The Carpenters' Company have arranged this lecture, and will be glad to welcome all interested.

**Future of the Manchester Botanical Gardens.**—Stretford's recent decision against the purchase of the Botanical Gardens, Old Trafford, was the subject of some discussion at the annual meeting of its proprietors, the Manchester Botanical and Horticultural Society, held on Thursday, the 4th inst., in the Town Hall, Albert Square. The report of the council expressed regret that the past year had been unsatisfactory from a financial standpoint, which was ascribed to the almost entire absence of summer-like weather during the season. A great portion of the report is taken up with a description of the negotiations between the society and the Stretford Council in reference to the suggested purchase of the gardens, a question which last week's poll decided against. The balance-sheet showed that an expenditure of £3,606 was made, and there was a deficit of £1,518 upon the year's working. The Lord Mayor, in moving the adoption of the report and balance-sheet, referred to the bad results of the year, largely due to the weather. This could not go on. The council could not face losses year after year, and the sooner something was done the better. Of course, the gardens had been offered to Stretford on what were considered reasonable terms, but by the vote of the people the purchase had been declined. Mr. John Wainwright said he still thought it a pity Stretford did not buy the gardens. He believed they were hardly aware of the value of the property. The land was worth 1s. per yard, which meant £80,000, and at the end of twelve years it could be used for building purposes. A resolution was adopted on the motion of Mr. Bowden, authorising the trustees and council, should they consider it expedient for the purposes of the society, to sell and dispose of the gardens of any part thereof. The resolution also authorised an increase of the security for a bank overdraft.

**"One and All" Gardening, 1904.**—This popular annual reaches its ninth issue this year. A first edition of 100,000 has been prepared to meet the growing demand. There are 200 profusely illustrated pages. The price is continued at 2d. Amongst the notable articles are "The Garden of Consolation," by the editor, Edward Owen Greening; "A Policeman's Roof Garden," "Board School Children's Flowers," "Floral Evolution," by James Scott; "Shakespeare's Plants" and "Shakespeare Weather Lore," by the Hon. H. A. Stanhope; "Appreciations of Gardening," by Louis Wain; "J. M. Harvey, the Actor-Manager," and numerous illustrated cultural articles.

**Gold-laced Polyanthus Mrs. Holden.**—A new introduction to the limited group of new varieties is always welcome. This new Polyanthus bears the name of Mrs. Holden, and was raised from seed from Mrs. Brownhill by Mr. G. Thornley, Middleton, Lancashire. It first appeared a few years ago, and, being full of promise, Mr. Thornley worked up a stock of it, and it is now being offered to the public. As the northern growers are freely buying it, it may be assumed that it possesses excellent qualities. It is a black ground flower with a clear yellow centre and lacing, and though I have been able to judge of its character from pips produced in winter, yet I am

sanguine it will not disappoint expectations. We shall doubtless have a chance of seeing this variety in London in April next, as the Midland and Northern growers will no doubt stage it. A correspondent, writing to me from Ireland, recently stated that he has a collection of more than a dozen varieties, and is adding to them as opportunity offers. In the moister climate of a portion of the Sister Kingdom the Gold-laced Polyanthus can no doubt be grown with a greater degree of success than in the south, where it by no means flourishes, despite the care which may be bestowed upon it. Our southern climate appears to be too exacting in summer, though the last two moist summers have been more favourable to its well being. Yet time was when named Gold-laced Polyanthus were most successfully grown round London.—R. DEAN.

**A new Raspberry—Queen of England.**—The Raspberry is so much liked in all households that any addition, and especially a superior fruit, to those we now possess will be found valuable. This fine seedling is the result of a cross between the well-known Raspberry Superlative and *Rubus laciniatus*; the first-named is a somewhat recent addition to the red sorts, and is a splendid cropper and very vigorous. It should be an excellent parent on that account; but it is strange that the *Rubus* should have given a golden fruit, as the Queen is a large rich yellow, and with a distinct foliage; the latter is studded with spines, in the way of the *Rubus*, and the foliage is in three divisions instead of five like the ordinary Raspberry. The fruits are in clusters like the Superlative, and borne later than the other white Raspberries, and the growth is much stronger. This is a great gain in light soils; indeed, I think it will prove of great value where other sorts fail to crop freely. It was given a first-class certificate when placed before the fruit committee, and the vote was unanimous, thus showing it was much liked. Since then I have been able to grow it by the side of older varieties, and am much pleased with it. I feel sure it will become a favourite, and doubtless the introduction of the Blackberry blood will give it increased vigour, as the latter parent is one of the best of the section, being very free and of good quality.—G. W. S.

**Soil work.**—The rainfall for the first month of the year was greatly increased by the continuous rains of thirty-six hours' duration on the last two days, and must have produced a degree of saturation of soil, following, as it did, on one of the wettest years remembered, that has rendered working not only difficult, but in many places impossible. That this excessive rainfall will be disastrous for cultivators of all descriptions there can be little doubt. Even light porous soils are having all plant nutrition washed out of them, as also being beaten very hard, just when ample aeration is so badly needed to sweeten them. Planting is terribly hindered still, as it has been from October onwards. When at Belfast last year Sir Norman Lockyer stated his belief that the third season of the wet cycle, because of the greater density of the sun spots, would be worse than either of the preceding ones; the statement perhaps did not secure the attention it deserved. The first month of the new year was so bad that it may well predict all that has been intimated.—A. D.

**Fruit culture in Scotland.**—It is interesting to find that, as mentioned on page 71, a material extension of fruit culture is to be promoted in Scotland. It may have been that the Northern Kingdom suffered less from rain and absence of sun than England last year, hence the enterprise mentioned. It would be unlikely that any material extension of fruit culture will be developed in the south, having regard to last year's bitter experience. Apart from that, the continuous rains render planting a matter of such difficulty that few will care to undertake it largely. We sadly need in the south a really good fruit season to give those who may wish to extend fruit culture here heart and hope. The mild and exceedingly wet winter so far is not conducive to do much, and we may well look forward with grave anxiety. It has been said that the failure of fruit bloom generally last year was largely due to

the effects of several very dry seasons on tree roots. That dryness no longer exists. Fruit buds on trees are plentiful. More now depends on the strength and fertility of the embryo, probably, than on anything else.—A. D.

**Derbyshire Horticultural Society.** The annual show will take place on September 14 and 15. The entries close for stock on August 12, implements on August 30, and for horticulture on September 7.

**A note from Ohio.**—I enclose a few little prints which may interest you. The Anemone, the single white, is the handsomest clump I ever saw anywhere. Last autumn it was considerably over 6 feet high. The reason for its success in this trying climate, where the thermometer goes to 20° below zero in winter, with sudden thaws perhaps a week after, when the thermometer rises to 60° above, is merely, I think, that the clump stands at the head of a tiny slope so that it is well drained, that it grows in rich heavy clay, and that Peach and Cherry trees grow so near that they protect it during blooming time from our early frosts and the fierce noonday sun. The double Whirlwind and the Queen Charlotte varieties do equally well, but I have no clumps so large. The Rose is a Queen of the Prairie, trained on a trellis along a back street. It here, too, likes a heavy clay soil. Neither of these plants get much attention in the way of mulching or fertilising, a ring of manure in the autumn is all.—(Miss) LUCY E. KEELER, Fremont, Ohio, U.S.A.

**A note from Worcestershire.**—The weather, though wet, keeps unseasonably mild for the time of year, and as a result the flower harbingers of spring have appeared earlier than last year in some cases. Cyclamen coum is especially good, and seems to have benefited by the incessant rain. *Iris unguicularis (stylosa)* has so far failed to flower. The last two summers it has missed its accustomed baking, and, though planted in a gravel walk at the foot of a warm wall, has produced a wealth of luxuriant foliage at the expense of the flowers. *Saxifraga burseriana major* is thickly beset with tiny buds, but I have to mourn the death of *Saxifraga Grisebachii*, which has succumbed to damp. *Anemone hepatica angulosa atrocærulea* is also just coming into flower, while Christmas Roses, *Erica carnea*, Winter Jasmine, and the little Winter Aconite are all in full bloom. *Narcissus pallidus præcox* does well on my light sandy soil, and promises to be in bloom earlier than usual this month. *Lithospermum prostratum* is a most random blooming plant. It is in bud now, indeed scarcely a month passes in which one could not gather some of its delightful flowers. Its relative, our native Gromwell (*L. purpureo-cæruleum*), grows slowly from seed. I sowed some in my cool greenhouse last year on February 15, and the hard shiny white seeds began to germinate early in January of this year. Canon Ellacombe, in "In My Vicarage Garden," remarks that when visiting Switzerland in September he was very interested in the fruits of this Gromwell, which he found in some of the woods in great abundance. "The interest," he tells us, "lay in this, that much of the shagreen from which our grandmothers' spectacles and etui cases were made was a manufactured article from asses' skin, into which was pressed hard seed, chiefly of the *Lithospermum*. As this is rather a rare plant in England I never could understand where the supply of seeds came from; but now, having seen it in such abundance in the woods of Switzerland, I can well fancy that the supply may have come from thence." Of Snowdrops I have now quite a large collection, but the rain splashes have sadly marred their purity. *Galanthus byzantinus*, of which I send you a few remaining flowers, was my first. It is a pity it is not more known, as it is very beautiful, and my real object in sending it is the hope that you will draw attention to its value. I believe I am right in saying that this species comes from around Constantinople. You will notice that its glaucous leaf closely resembles that of *G. plicatus*, while the narrow green and white tube, which is such a marvel of Nature's handiwork, reminds one of *G. Elwesii*. I send you this latter just for comparison. Most of the other Snowdrops, such as

*G. Fosteri*, *G. Imperati*, *G. Elwesii unguiculatus*, *G. Elwesii Erythrae*, and others are not fully out to-day (February 1), but a week hence should see them at their best. My plant of *G. Imperati Atkinsii*, which was figured in THE GARDEN last spring, has made good increase, and is already in flower. Two *Corydalis* species are in bud—*kolpakowskyana* and *angustifolia*. This latter was distributed last summer by Van Tubergen, and though an old plant, being first described by Bieberstein in his "Flora Taurica," vol. ii., page 146, under the name of *Fumaria angustifolia*, is very rare in cultivation.—ARTHUR R. GOODWIN.

**Clematis calycina.**—This Clematis is comparatively common in the south-west, where it grows to a considerably greater height than the 10 feet mentioned in the note on page 11. I know cases where it has reached the eaves of houses fully 20 feet in height, and in a friend's garden it has clambered up a tree to a height of over 25 feet. The greenish white flowers with their internal spotting of purple are not particularly attractive, their chief value being their advent in midwinter, for in most seasons expanded blossoms may be found in December, while during January and February they are produced in abundance. This Clematis is better known by the name of *C. balearica*, which indicates its native habitat. In the note referred to the specimen at Rosehill, Falmouth, is mentioned. This is growing over a trellis in company with another Clematis often confounded with it, namely, *C. cirrhosa*, a native of Southern Europe. This flowers considerably later than *C. calycina*, and its blossoms, of the same greenish white, are unspotted, while its foliage is not so deeply cut. When at Rosehill I was able to compare one of the last flowers of *C. calycina* with the earliest of *C. cirrhosa*, and also the foliage of the two respective plants. The illustration of *Clematis cirrhosa* in Nicholson's "Dictionary of Gardening" is apparently, from its deeply-cut leaves, a representation of *C. calycina*.—S. W. FITZHERBERT.

**The flowering of Bamboos.**—During the past season several notes have appeared recording the flowering of Bamboos, *Arundinaria Simoni* being the species referred to in almost every instance. This Bamboo flowered very generally in the south-west during 1903, and specimens now present a wretched appearance, being apparently sheaves of dead and brown canes. However, this species is said to recover after seeding, so that it is to be hoped that its disfigurement is only temporary. This, unfortunately, is not the case with some other species, which die after seeding. The splendid clumps of *Arundinaria nobilis* at Menabilly, which are over 25 feet in height, are the progeny of the original plant raised from seed sent from North China. This died in 1872 after thirty-three years of life. These are now thirty-two years old, so that it is to be feared that their lives will not be much further prolonged. I lately saw a specimen of *Phyllostachys boryana* in flower, and have heard that plants of *P. Henonis*, to my mind the most beautiful of all the Bamboos, have flowered in Cornwall, but this is merely hearsay evidence, which I have not been able to verify. It is to be hoped that the report is incorrect, for the death or even the temporary disfigurement of fine specimens creates a sad blank in the Bamboo garden.—S. W. FITZHERBERT.

**Edinburgh market gardeners and railway rates.**—As was reported in THE GARDEN some time ago, the market gardeners of the Edinburgh district were threatened with a serious hindrance to their business by the proposal of the local railway companies to introduce new regulations regarding the conveyance of their produce. The combined action of the Market Gardeners' Association and the Scottish Chamber of Agriculture led to the matter being laid before the Board of Agriculture, from which a letter was read at the meeting of the Chamber of Agriculture on the 3rd inst. It was stated, however, that the companies had not put the proposed regulations into force, and it was thought that the agitation of the market gardeners and others had thus been productive of some benefit. As they have not been withdrawn, however, it is recognised by all interested that there is yet some danger that the

regulations may be enforced to the great injury of the market gardeners, whose industry requires the frequent dispatch of small quantities of produce.

**Jasminum nudiflorum.**—During the past month the clear gold of the Winter Jasmine has formed an attractive picture on sunny days, at a time when little bright colour is to be found in the garden landscape with the exception of the cardinal and golden Willows and the ruddy bark of some of the Dogwoods. In a recent note it was recommended as a companion for Ivy, since the dark, shining leaves of the latter showed off its bright flowers to such advantage. Such a combination is certainly a very effective one, but I doubt if a more perfect associate for the winter Jasmine can be found than *Cotoneaster microphylla*. In a remote Devon village I saw, one Christmas, a thatched cottage with its front entirely covered with the mingled growths of these two plants, both at the zenith of their beauty, the Jasmine a veil of clear yellow, and the thickly clustering crimson berries of the *Cotoneaster* forming a glowing background for the flowers. It was a picture as charming as it was unique, for there are but few who, for the sake of brightening the midwinter days, would forego the wealth of summer beauty provided by climbing Roses, Passion Flower, Solanum, and other flowering creepers. However, when such an instance is met with, its originator deserves the thanks of all lovers of the beautiful for having had sufficient strength of mind to dispense with a summer flower-clad wall in order that the dull December days might be brightened by a cheery display of colour. In large gardens the same restrictions do not apply, for, while the cottage has but one front wall, there are many sites that may be chosen in spacious gardens where the two subjects here alluded to may be associated, and where their lengthy season of ineffectiveness may be rendered immaterial by the growth of summer-flowering climbers in their immediate vicinity.—S. W. F.

**The Baxter Park, Dundee.**—A number of improvements are at present in progress in this park, and the total cost of these is estimated to amount to at least £1,200. They are being carried out under the supervision of Mr. Carnochan, the Parks Superintendent, and when completed will add much to the beauty of the park. A considerable amount of pruning trees and shrubs has had to be undertaken, and the result will be that the natural forms of the plants will have room to develop so as to show their real beauty. It has been found necessary to remove a number of trees and shrubs, so crowded together were they in some places. New flower-beds are being made and others remodelled, while the pavilions and their accommodation are also being considerably improved.

**Royal Caledonian Horticultural Society.**—This society has issued the prize-list and rules for its spring and autumn shows, to be held in the Waverley Market, Edinburgh, on May 25 and 26 and September 14 and 15, copies of which can be obtained by application in writing to the secretary, 18, Waverley Market, Edinburgh. The changes of importance from the prize-lists of last year are not numerous, but two of these deserve special mention. The first, which is of the highest importance, has been made possible through the munificent gift of Mr. W. H. Massie (of Messrs. Dicksons and Co., Waterloo Place), of a silver challenge trophy of the value of 50 guineas for a Grape competition, the trophy to become the property of the exhibitor who wins it three times. The conditions have been drawn up after consultation with several of the best Grape competitors, and the trophy is to be competed for at the autumn show. The schedule stipulates eight bunches of Grapes, not more than two bunches of any variety, and the prizes are: First, the challenge trophy (to be won three times), with £15 in cash and a gold badge; second, £10; third, £5; fourth, £3. Each bunch will be judged on its individual merits and points awarded. A maximum of ten points may be given to Muscat of Alexandria; a maximum of nine points may be given to all other Muscats and Black Hamburgs; a maximum of eight points to all other varieties; the bunches to be staged singly, if possible, and the whole arranged on a table space

6 feet by 4 feet in two tiers, 2 feet in width. For the purpose of this competition Bowwood Muscat, Charlesworth Tokay, and Tynninghame Muscat cannot be shown as distinct varieties with Muscat of Alexandria. Gros Maroc and Cooper's Black are also considered synonymous. Superior cultivation and finish will be considered of the greatest importance. Each collection must be decorated; flowering or foliage plants (in pots not exceeding 5 inches in diameter), also cut flowers or foliage in glass or ware, or loose, allowed at the exhibitor's discretion. There is little doubt that the competition for this Scottish challenge trophy for Grapes will be of the highest interest to horticulturists in the kingdom. Of less importance, but a change in the right direction so far as the larger vegetable growers are concerned, is the abolition of the classes for collections of vegetables and the substitution of a class for a display of vegetables, with a table space of 6 feet long by 6 feet wide for each collection, and with prizes of £4, £2 10s., and £1 10s. The prizes are to be awarded for points as given in a maximum scale in the schedule.

**Grants to horticultural objects in Scotland.**—At a meeting on the 3rd inst. of the Lord Provost's committee of the Corporation of Edinburgh it was agreed to recommend that a grant of five guineas be made to the funds of the Working Men's Flower Show of Edinburgh. Few corporations are more disposed to assist horticulture in this manner than that of Edinburgh, and the show in question has done much to interest many in the city in the cultivation of plants and the brightening of many a court and dingy street. The schedule of the society is a most comprehensive one, and prizes are offered for plants not often seen at shows. One valuable special section is that confined to dwellers in what may be called the "congested districts" of the city. The other grant we have to record comes from what is known as the Glasgow Public House Trust—a body formed for the establishment of licensed houses on the Gothenburg principle—which means to devote the profits, after payment of a reasonable fixed rate of interest to its shareholders, to public objects in its sphere of operations. The trust has an ale and porter license in the village of Hallside, Newton, and from the profits of last year £10 have been given for prizes at the village flower show and as premiums for the best kept gardens.

**Corydalis angustifolia.**—Although the early flowering species of *Corydalis* are not so free and lack the brighter colouring of those which flower later in the season, they are interesting and useful on account of the earliness with which they come into bloom. Hardy tuberous rooted perennials, they are generally found in their native habitats in rather moist and shady positions, so that a similar position should be assigned to them in the rock garden or Fern border. They are also useful for growing in pans for the alpine house. The above species is a native of the Caucasus and Armenia, and was exhibited at the last meeting of the Royal Horticultural Society by Messrs. W. Cutbush and Son. It reaches a height of 4 inches to 8 inches, and has tuberous roots. The root leaves are biternate, on long, slender petioles, the divisions of the leaves being long and linear. The stem leaves are two in number, also biternate and again deeply divided. Laxly disposed in a short raceme with bracts, which are divided to the middle into three divisions, the flowers are somewhat cream coloured, with a long spur. Other species now in flower are *C. kolpakowskyana*, from Western Turkestan, a plant that has been in cultivation since 1879, with glabrous, much-divided leaves, and stems about 6 inches high, bearing racemes of pink or purple flowers with long spurs. *C. ledebouriana*, also introduced in the same year, is remarkable for its peculiar, ternately divided, glaucous leaves, which are arranged whorl-like about one-third of the way up the stem, which is 6 inches to 9 inches high. The flowers have been described as deep, vinous purple with pinkish spurs, and have entire ovate bracts. It is a native of Siberia.—W. I.

**Catalogue and Culture Guide of the National Dahlia Society.**—Mr. W. P. Tulloch, hon. secretary of the National Dahlia Society, writes: "Owing to the rapid

revival of interest in the Dahlia during recent years, due to the development of the Cactus flowered type, my society, as the leading authority on all Dahlia matters, has prepared and issued the enclosed booklet, with the object of affording assistance to growers both in the matter of culture and choice of varieties. The comparative ease in obtaining the best results from the Cactus Dahlia as compared with the older show and fancy types, brings it within the reach of all, but, in spite of this, no work on its culture has yet been issued." To all interested in the Dahlia this book will be indispensable. Mr. Edward Mawley (president of the society) contributes an introduction, and there follows "The Bibliography of the Dahlia." Among the many useful and practical articles contained are "Situation and Soils," "Propagating and Management under Glass," by Mr. Tulloch, assisted by experts; "Manuring, Watering, Lifting, and Storing," by S. Mortimer; "Enemies of the Dahlia," by H. L. Brousson; and "Raising Seedlings," by J. T. West. Mr. Tulloch further writes upon "The Popularity and Rapid Development of the Cactus Dahlia"; and the "Culture for Exhibition," by J. Stredwick; "Exhibiting," by J. Burrell; "The Cactus Dahlia for Garden Decoration," by J. T. West; and "The Cactus Dahlia for House Decoration," by F. G. Treseder, are also good reading. The above chapters chiefly concern the Cactus Dahlia. Show and Fancy, the Pompon, and the Single are treated by experts. Full descriptive lists of varieties of all sections are given at the end of the book, so that the Dahlia grower will find instruction upon all possible points.

## RECENT PLANT PORTRAITS.

THE *Botanical Magazine* for February contains portraits of

*Lysichitum camtschatcense.*—Native of North-East Asia and North-West America. This is also known under the synonyms of *L. camtschaticum*, *L. camtschatcensis*, *L. japonicum*, *Symplocarpus kamschaticus*, *Arctiodracon japonicum*, *Pothos camtschaticus*, *Dracontium foliis lanceolatis*, and *Dracontium camtschatcense*. An exceedingly handsome and conspicuous flowered aroid, with large gold-coloured spathes resembling those of *Calla elliptica* and marbled foliage like that of a *Maranta*.

*Bulbophyllum auricomum.*—Native of Burma. Also known under the synonyms of *B. feniseccii* and *Dendrobium tripetaloides*. An inconspicuous and small white-flowered Orchid of little beauty.

*Corydalis Wilsoni.*—Native of Central China. This is a beautiful golden-flowered fumitory raised from seed sent to Messrs. Veitch by their collector, Mr. E. H. Wilson, and named after him.

*Sauromatum brevipes.*—Native of the Sikkim Himalaya. Also known under the synonyms of *Typhonium pedatum* and *T. brevipes*. A curious and rather ornamental aroid, producing very freely a number of slightly spotted, cream-coloured flowers with carmine centres, and rising out of the ground without any kind of foot-stalk. This interesting plant bloomed for the first time in Europe in the University Botanic Garden at Cambridge in 1902, whence it was sent to Kew by their curator, Mr. Lynch.

*Melaleuca uncinata.*—Native of temperate Australia. Also known under the synonyms of *M. hamata*, *M. Drummondii*, and *M. semiteres*. This is a rather inconspicuous white-flowered shrub of little beauty.

The first number of the *Revue Horticole* for February gives a group of four varieties of the new race of Dahlias originating in the Botanic Garden of the Parc de la tête d'Or at Lyons and known as Dahlias à collerette. The varieties figured are named respectively President Viger, Maurice Rivoire, Mme. Le Page Viger, and Massange de Louvrex. These flowers are a distinct new break in single Dahlias, and are very showy and free-flowering. Two varieties were sent out by Messrs. Rivoire of Lyons in 1902, two more in 1903, and this year six more are offered by the same firm.

The *Revue de l'Horticulture Belge* for February contains a portrait of a double-flowered Indian

Azalea named Rose de Noel, which is a very good variety, but hardly worth figuring on a coloured plate where some new or rare plant might have been portrayed.  
W. E. GUMBLETON.

KEW NOTES.

INTERESTING PLANTS IN FLOWER.

Temperate House.

ACACIA ACINACEA, A. baileyana, A. Drummondii, A. glaucescens, A. pubescens, A. verticillata, and others; Camellia reticulata, Eupatorium versale, Loropetalum chinense, and Rhododendron grande.

Palm House.

Acokanthera venenata, Clavija macrophylla, Dracaena reflexa, and Saraca indica.

Orchid Houses.

Arpophyllum spicatum, Cœlogyne macrobulbon, C. sparsa, C. sulphurea, Cynorchis compacta, C. lowiana, C. villosa, Cypripedium nigrum, C. rothschildianum, and others, Dendrobium Andromeda, D. burfordiense, D. eusmum, D. nobile, D. primulinum, D. speciosum, D. superbiens, D. wardianum, Lælia virens, Lycaste lasioglossa, Masdevallia polysticta, Odontoglossum Edwardii, O. pardinum, Oncidium macropetalum, O. tetrapetalum, Ornithidium coccineum, Phaius Blumei, Platylinis arachnites, P. glumacea, Saccolabium bellinum, Selenipedium cardinale, S. klotzschianum, S. Roezlii, S. Sedeni, S. Sedeni var. candidulum, Spiranthes plantaginea, and Trias picta.

Range.

Æchmea glomerata, Calathea picta, Caraguata cardinalis, Euphorbia fulgens, Pitcairnia corallina, Plectranthus crassus, and Sonerila peperomiaefolia.

Greenhouse.

Acacia obliqua, Cheiranthus kewensis, Coleus thyrsoides, Iris reticulata, Magnolia stellata, Primula obconica, P. sinensis vars., Pyrus floribunda, Senecio petasites, Tulips, and many other things.

Alpine House.

Anemone blanda, A. coronaria var. syriaca, Bulbocodium vernum, Colchicum crociflorum, C. hydrophilum, C. montanum, Crocus alataviens, C. ancyrensis, C. biflorus, C. chrysanthus, C. Olivieri, C. reticulatus, C. Sieberi, Cyclamen Coum, C. ibericum, Eranthis cilicica, Iris Histrio, I. reticulata var. Krelagei, Primula megaseefolia, Saxifraga Albertii, and S. burseriana var. major.

Herbaceous Ground and Rock Garden.

Adonis amurensis, Crocus Fleischeri, C. pestalozzei, C. Sieberi, S. suaveolens, and others, Iris Danfordiae, I. Histrio, I. histrioides, I. stenophylla, and I. Tauri.

Arboretum.

Chimonanthus fragrans and var. grandiflora, Hamamelis japonica, Lonicera fragrantissima, and L. Standishii.

TREES AND SHRUBS.

ULMUS PUMILA.

OF the many species of Ulmus in cultivation, this is one of the most distinct, especially during early winter, for long after all the leaves of other Elms have turned yellow and fallen those of U. pumila remain quite green. In early December not a single leaf on a fine specimen in the Elm collection at Kew showed signs of decay, while all the other species and varieties in the vicinity were leafless. U. pumila is a native of Northern Asia, and is said to vary considerably in stature in the various places where it is found. Sometimes it is met with as a fair sized tree, at others

as a mere bush 2 feet or 3 feet high. At Kew the largest specimen is upwards of 20 feet high, with a symmetrical, well-balanced head. The branches are fairly thin and twiggy, and, together with the small leaves, give the tree a graceful habit. The leaves are ovate, or ovate-lanceolate, with serrated margins. They vary considerably in size, some being barely half an inch long, while others are nearly 2 inches long and nearly an inch wide. In colour they are deep green, and in texture they are thicker and firmer than those of most Elms. For gardens where small-growing trees are desired this Elm would be a suitable one, its leaves hanging so much later than those of most deciduous trees.

W. DALLIMORE.

SHADE TREES.

OAK.

So far as experiments have shown, Oaks are the best shade trees for cities. They are strong, durable, and beautiful, and have few enemies. Owing to a popular notion that Oaks grow slowly, they have heretofore been little planted on streets, but several cities are now beginning to make use of them. The oldest Oaks are to be seen in Hamburg, where the city has encroached upon the ancient forest. An avenue of this same species (Q. pedunculata) has been recently planted in Cologne, which, so far as I have observed, is the only city in Europe that has made use of the Oak for street planting. In this country the oldest Oaks may be seen in Washington, where the Red Oak and Pin Oak in particular have been very successfully grown. Red Oaks have also been recently planted in Boston between Franklin Park and Huntington Avenue. The best species of Oak are probably the Red Oak, the Pin Oak, and the Scarlet Oak; but there are several other species almost as good as these, though none of quite so rapid growth as the Red Oak. The White Oak is somewhat objectionable on account of its slow growth, and because its leaves remain upon the tree after they are dead. The number of Oaks given in the list might be much increased. Those selected are of various sizes, and have been given a trial.

SYCAMORE.

The Sycamore is an excellent shade producer, the leaves appearing at the proper time in this latitude and remaining on the tree as long as could be desired, when they give place to the persistent and graceful fruit. With a little protection it passes the northern winters uninjured, and develops rapidly into a splendid and shapely tree, large enough for the widest avenues or capable of being adapted by pruning, to which it most readily submits, to very narrow streets. Such is the activity of its young wood and bark that the stem is at times completely girdled without appreciable injury, and the outer layers of its cortex are annually sloughed off during late summer and autumn, leaving the new layers beneath entirely free from soot and dirt accumulated during the summer. It is partly due to this, perhaps, that it enjoys, with the Ailanthus, the distinction of being best adapted to parts of cities where smoke and dust abound.

The only serious enemy of the Sycamore is a fungus which attacks its shoots and young leaves in early summer, greatly disfiguring the tree. In some cities of Southern Europe complaint is made of the thick hairy covering which becomes detached from the young leaves and twigs and gets into the nose and mouth, producing an inflammation known as the "Sycamore cough." This tree is, however, most widely and abundantly employed in the cities of India, Persia, and Europe, while in America it is deservedly growing more popular as a street tree every year. In London it is considered by many to be the only tree that will thrive in the dirt and smoke of so large a city.

Of the two common species of Sycamore, the Eastern is smaller and of closer growth than our native species, though less hardy and less beautiful in form. It was for some time thought also that the Eastern species was less subject to attack by the Sycamore fungus, but this is probably not the

case. In this country the Oriental Sycamore is usually preferred, while in Paris the Western species is used exclusively, since it seems to conform better to the style of pruning adopted in that city.

AILANTHUS.

The Ailanthus is another importation from the Orient, less common than the Oriental Sycamore, and, on account of some especially objectionable qualities, very unpopular with the public. Some of these qualities, however, are not serious faults, and may be entirely corrected with proper care. For example, the unpleasant odour at blossoming time is confined to the male flowers, and trees bearing these flowers need not be cultivated. The habit of sprouting profusely at the roots, though dangerous to pavements, renders the propagation of the Ailanthus extremely easy, and also makes it possible to select only the desirable trees. Those who object to the odour of the male flowers for two or three days, however, must endure the sight of the ugly brown fruit clusters which often hang upon the tree throughout the winter. A fault which cannot be remedied is the early maturity and disfigurement accompanying rapid growth. When young the Ailanthus is vigorous and shapely if properly trained, and its large leaves are green until frost, but most of the old trees I have seen present a very scraggy and unsightly appearance. There are fine avenues of this tree in Paris, where it is unrivalled for vigour and general thriftiness. When these trees show signs of failing they will be cut down and the avenues replanted. The qualities which make the Ailanthus especially desirable as a shade tree are its ability to grow in even the most barren soil and to thrive in the midst of smoke and dust and other adverse surroundings peculiar to city streets. When the question is not what tree would be the most ornamental, but what tree would live and grow in a particular locality, then the Ailanthus should certainly be considered.

W. A. MURRELL, in Bulletin of Cornell University. (To be continued.)

CHRYSANTHEMUMS.

MINIATURE POMPON CHRYSANTHEMUMS.

WE have one section of the decorative Chrysanthemums of which little is known, so much that there is a risk of many charming sorts being lost sight of. I refer to the small-flowered Pompoms, such as Snow-drop and Primrose League. There are few gardens in which these miniature-flowered Pompons are grown. Chrysanthemum growers, in their haste to get the large blooms of other sections, appear forgetful of the existence of these small-flowered sorts, and seldom are the flowers represented at the exhibitions.

The list of miniature-flowered Pompons is a very short one; more's the pity. The fact is this: the varieties have been introduced at different periods during the last twenty years, and, because there has been no competitive class for them at the shows, the orthodox grower has disregarded them. A careful perusal of the trade catalogues shows that there is only one firm who make a special list of these "small, well-formed flowers," and in this respect the unique list is the catalogue of Messrs. H. Cannell and Sons has much interest. Some of the better kinds are met with here and there in others, but none of them compare with the one I have just named. These small-flowered Pompons should find a place in all collections which have to provide a quantity of cut flowers in November and December. Their small size, dainty form, together with the graceful sprays in which they may be gathered, have much charm. For dinner-table decorations the sprays are excellent, and for the numerous smaller receptacles so frequently in use for all forms of indoor decoration these sprays only need to be seen to be appreciated.

No one seems to talk about these flowers, and yet they are unequalled in many respects, for the

## THE LILIES.

## LILIUM ELEGANS (THUNB.).

*(Continued from page 88.)*

conservatory as well as for use as cut flowers. A vase of freely-flowered sprays of some of the sorts, contrasted with a bloom or two of some large exhibition Japanese variety, is a sight worth seeing.

The present is an excellent time to insert the cuttings, and these, when rooted, should be potted up without delay. When established in their small pots the young plants should be topped or pinched, and this work repeated at each succeeding 4 inches to 6 inches of growth. Pinch the points out of the plants for the last time about the middle of July, from which point they should be grown on to their terminal buds. The terminal buds should be well thinned out, so that the flowers are not too crowded. Plants treated in this way invariably give a handsome reward. Those worth growing are the following:

*Snowdrop.*—As the name implies, this is a beautiful white variety, and very free. The flowers are sometimes described as button-like; but when well grown, they are almost globular. At its best in late November. Height 3½ feet.

*Primrose League.*—This variety is sometimes spoken of as Yellow Snowdrop. As a matter of fact, it is a primrose-coloured sport from Snowdrop, and in every respect but colour is the same as the parent variety.

*Miss Gertie Waterer.*—This is another sport from Snowdrop, the colour in this instance being a pleasing flesh-pink shade. Some years ago it was exhibited before the floral committee of the National Chrysanthemum Society, and, I believe, then received a first-class certificate. Since that date, however, some of the stock appears to have reverted to the original. Where the true stock can be procured, it is worthy of inclusion in the smallest selection.

*Katie Manning.*—In this variety we have a small-flowered Pompon of comparatively recent introduction, and one that has a good future before it. The flowers are freely produced, and are also of good form. The colour may be best described as rosy-bronze. In bloom in early November. Height about 2½ feet.

*Purity.*—This is another pure white sort, somewhat similar to Snowdrop, but less sturdy in growth. The sprays make up into handsome bunches for vases. Very dwarf.

*Lune Fleurie.*—This is a curious, though extremely interesting plant. The numerous pretty little globular blooms are fimbriated, and their colour is a deep bronzy-orange. This variety was introduced in 1889, and received a first-class certificate from the National Chrysanthemum Society.

*Model of Perfection.*—Introduced by the late Mr. Forsyth in 1873, and still a distinctly pretty little Pompon. As the name suggests, the form of the flower is exquisite, being neat and globular. Colour rosy-lilac. A November-flowering plant. Dwarf.

*Victorine.*—A French introduction of 1889, having small blossoms, rosette-like in form. Colour maroon-crimson. To be seen at its best the plant should be disbudded rather freely. Dwarf. In flower in November.

*Little Pet.*—Another delightful miniature of globular form and prettily imbricated. Colour orange-red, passing to chestnut, with a golden reverse to the florets. There is also another variety bearing the same name, that the distributor describes as a small, neat, blush flower.

*Yellow Gem.*—This is a pretty October-flowering Pompon that succeeds as well in the open border as in pots. The flowers are small, neat, and globular, and the florets are fimbriated. Colour deep yellow. Height 2 feet. Bushy habit.

*Dolly.*—Although not quite so small as some of the others, this is a very charming little flower that pays for good culture. The colour is a clear canary-yellow, and the blossoms are of good form and beautifully finished. In flower in late October. Nice habit.

*Little Dot.*—By several the blooms of this variety are regarded as the smallest of the family. They are quite distinct from all others. Colour yellow, edged red and brown.

Others might be added, but this selection of a dozen sorts is quite enough for beginners.

D. B. CRANE.

*VAR. ORANGE QUEEN.*—One of the best Lilies of this type, and a valuable garden plant, bright in colouring and refined in form. It has stout stems above a foot high, clothed with broadly lance-shaped, reflexing, glossy green leaves, and bearing one to three flowers, the petals of which are broadly spoon-shaped, the tips rounded, and remarkable for their texture and finish. Colour a rich orange-buff, almost unspotted, and of a uniform tint throughout. A grand Lily, vigorous, free in growth, and very hardy. Common in cultivation. Flowers in mid-July.

*Var. ornatum* (the Ornate L. elegans).—A great rarity, best described as a glorified *alutaceum grandiflorum*.

*Var. purdinum.*—See var. Wilsoni.

*Var. Peter Barr.*—A fine Lily of the *alutaceum* type, new to cultivation, coloured a pale orange-buff, the petals very long but narrow, and lacking the finish and texture of petal that is so important a feature of this type of Lily. Flowers in July.

*Var. pictum.*—See var. bicolor.

*Var. Prince of Orange.*—A very robust, many-flowered form of *alutaceum*, with stout stems, and about a foot high; the flowers are a soft shade of buff in colour, and sparsely spotted internally, and generally arranged in umbels of three to five. As a garden plant it excels many of its fellows in vigour of growth and freedom of flowering. Common in cultivation. Flowers in July.

*Var. robustum.*—See *marmoratum aureum*.

*Var. staminosum.*—See *fulgens flore-pleno*.

*Var. The Sultan.*—A counterpart of Prince of Orange in habit, but coloured very dark crimson, and spotted black low down internally. The best sombre-coloured dwarf Lily for general purposes. Not common in cultivation. Flowers in July and August.

*Var. Van Houttei* (Van Houtte's Crimson L. elegans).—A very popular and valuable variety for every garden use. Its stems are stout, 12 inches high, and bear two to three rich crimson-scarlet flowers; the petals are exceptionally broad, expanding fully but not reflexing. They have scarcely any tube, but spring at right angles from the stem, and they span fully 6 inches across. A few linear spots of black occur low down each petal, and the extreme base is yellow. It is the nearest approach to the rare *Horsmanii* known to us.

*Var. venustum.*—See *armenaicum*.

*Var. Wallacei* (Wallace's L. elegans).—A strong-growing plant with globose bulbs 2 inches in diameter, stems 2 feet to 3 feet long, slender, the leaves linear and ascending. Its flowers are borne in umbels of three to five, coloured a deep coral red, darker near the tips, and spotted internally with brown; they reflex as fully as in *Batemannia*. The bulbs are often compound, and thrive in a deeply tilled moist soil. Common in cultivation. Flowers in late August.

*Var. Wilsoni* is a wide variation of L. elegans, and with a peculiar habit of its own. It has large bulbs resembling those of L. tigrinum. The stems travel under ground some distance before they pierce the surface, and they bear several bulbils along the covered portion. Height above ground 2 feet. Leaves broadly lance-shaped, thickly clothing the stems, and covered with a cobweb-like covering in a young state. Flowers in a short spike of ten to fifteen, each 5 inches across, deeply cup-

shaped, the petals broad and very straight, coloured rich orange, spotted internally with crimson low down the funnel. A very vigorous form. Common in cultivation. Flowers in August.

**CULTURE AND USES.**—The elegans group of cup-flowered Lilies are good, all-round border plants, mainly of very dwarf stature and suitable for associating with low growing herbs in the forefront of beds and borders. They are also well adapted for pot culture. With the exception of *Wilsoni*, *Batemannia*, *Wallacei*, and E. L. Joerg, whose culture we will describe later, all may be treated similarly. They require good cultivation to maintain their flowering strength, and we have found a liberal dressing of leaf-soil to the staple the best rooting medium of all. They grow well in a sunny exposure or in shade, preferring a light, well-drained soil of deep tilth. They make quantities of stem roots, hence deep planting should be the rule, and, in order that the rooting bases may be screened from drying winds and strong sunshine, they should be planted either closely together or with a carpet of *Aubrietia* or similar plants about their stems. We have seen them used effectively in small colonies amid shrubs and in association with Bamboos and other grasses, and they are magnificent in beds; but their season of flowering is too short in its duration to warrant extended use in this direction. They make excellent pot plants, and when grown carefully they develop into fine plants under glass. Large and roomy pots are more satisfactory than smaller ones, as these admit of six to twelve bulbs being grown together—the only way in which these dwarf Lilies can be fully appreciated. Even in border culture small colonies associated with other plants are much more effective than scattered units. *Batemannia*, *Wilsoni*, and E. L. Joerg require a strong soil. These Lilies grow but slowly, and ripen late in the season; they require warm situations and plenty of water in dry summers, or their leaves will become disfigured before the flowering season and their bulb development will be slight. L. *Wallacei* succeeds best in rich vegetable loam; its best situation would be in the drier places of a bog garden. It succeeds well with *Iris Kämpferi* on the margins of waterways.

*L. excelsum* (Hort.).—See *testaceum* (Lindl.).

*L. Fortunei.*—See L. *tigrinum Fortunei*.

G. B. MALLETT.

*(To be continued.)*

## WINTER FLOWERS AT EXETER.

## NORTHERNHAY PUBLIC GARDENS.

IN the duller part of the winter, with scarcely a day without rain, and an almost complete absence of sunlight, so that no inducement has for weeks been offered to the native vegetation to brighten our hedgerows, except by an occasional group of the lesser Periwinkle and a few berried shrubs, it was a pleasant change from sloppy streets to suddenly come upon quite a bright show of Primroses in a sheltered border of some considerable length in the public gardens at Northernhay, Exeter, on one of the wettest days possible in the first week in January. In these well-kept grounds, which may be correctly described as being situated in the centre of the city, is a border thickly planted with Primroses mixed with Ivy, and at the time specified every clump was full of the favourite yellow flowers and buds.

Northernhay is a favourite resort of the citizens of Exeter, hands playing here during the summer evenings. The place receives careful attention

from the corporation, and the rock plants, with a backing of shrubs, which is a special feature in the centre of the grounds, have all been recently named with neat iron labels painted black with white letters and fixed in the ground with two strong wire prongs. These labels have the advantage of being permanent, are quite unobtrusive, and cannot be distinguished at a short distance. For the most part the names are correctly spelt, but in a public garden it should be made impossible for even a single error to occur.

From these grounds, looking across the valley where is situated the South-Western Railway Station, and through which the line runs from Waterloo to Plymouth and North Devon, the glass houses in the nursery of Messrs. Robert Veitch and Son are distinctly seen. Making our way thither in the hope of seeing some floral brightness, the dwarf hedge of *Cotoneaster microphylla*, which borders the steps on either side of the path leading to the main walk, attracts attention by its numerous bright red berries, which, however, are considerably outdone by *C. pannosa*, a shrub of which is seen a little further on literally covered with berries of a brilliant scarlet. This handsome shrub, which attains to a height of 6 feet or more, has the double attraction of bearing a profusion of white flowers in the summer succeeded by the clusters of berries. It flourishes out of doors in this part of England.

The persistent rain has the effect of driving one under the protection of the glass houses, where, in a pleasant temperature, one can linger and enjoy the touches of colour. A bright effect is produced by a mass of *Begonia Gloire de Lorraine*, the golden-yellow stars formed by the stamens lighting up the whole mass. Near this was a nice group of *Browallia speciosa major*, the West Indian Forget-me-not, the rich deep blue flowers of which formed a striking contrast to those of the *Begonia*. The pale yellow flowers of *Calceolaria Burbidgei* interspersed with the bright green foliage were also much in evidence. A newly-revived old friend which is just now attracting some attention in consequence of its appearance at the last show of the Royal Horticultural Society, namely, *Jacobinia chrysostephana*, required no introduction, as its terminal clusters of orange-yellow flowers raised above the surrounding foliage went far to impart brightness and relief to the outside gloom, besides which it pointed to a fact that there are many of the older introductions that are quite worth reviving, and can compare well with those of more recent appearance, a matter which was emphasised by Mr. Veitch himself, who, indeed, has a strong liking for many of the older and best known plants.

Amongst *Acacias* now well in flower we noticed a nice group of *Acacia platyptera*, the golden buds of flowers being abundantly produced on nice bushy plants about 12 inches to 18 inches high; *Correa cardinalis* and *ventricosa* were brilliant with their bright red and pink and white tubular flowers. Though these were small compact pot plants, both species have proved quite hardy against a wall in several parts of South Devon and Cornwall. Near to these and well covered with flower-buds were groups of *Boronia megastigma*, *Eriostemon linariaefolius*, *E. nerifolius*, and *E. scaber*, as well as the peculiar *Grevillea alpina*, with its curiously twisted pink and white flowers. A new introduction from China, with bright yellow flowers and green blotch at the mouth, cannot fail to attract, especially at this time of year. It is *Corydalis thalictrifolia*, and is described as a profuse and continuous bloomer, the racemes of flowers are about 6 inches long, and are produced freely during summer, and if the plant be taken indoors in the autumn it will keep flowering through the winter. As a conservatory pot plant or for hanging baskets it is said to be equally valuable. The pretty blue *Coleus* (*C. thyrsoideus*) was just coming into flower, and amongst plants interesting rather than beautiful at the present time was one of the Bottle Brushes (*Metrosideros floribunda alba*) in fruit.

Without enumerating other plants we may, perhaps, close this notice with a reference to the new *Borecole* called the Albino, which was shown me, not in a growing condition, but as a fresh

decorative plant for vases. The heart leaves are of a creamy white, and the outer leaves, which are much crested, are white, irregularly edged with bright green. It is stated that as the winter advances the leaves become whiter, and in the early spring it is an object of great beauty. The plant is perfectly hardy, and might be well grown for decorative purposes in addition to its edible qualities. It has obtained an award of merit from the Royal Horticultural Society.

JOHN R. JACKSON.

Claremont, Lympstone, South Devon.

## NOTES ON HARDY PLANTS

### RAMONDA PYRENAICA.

**R**AMONDA PYRENAICA is a plant that no rock garden should be without. It thrives best in an upright fissure on the shady side of rocks, and loves abundance of moisture, but is, nevertheless, very averse to having water resting in the centre of its rosette of leaves, and requires therefore to be planted sideways. *R. pyrenaica alba* is still rare and expensive. *R. Heldreichi* has hairy leaves, and requires less shade and moisture than *R. pyrenaica*. *R. serbica* is distinguished by yellowish coloured flowers. G.

### HELLEBORUS NIGER.

THE flowers of this useful hardy plant are always acceptable, as they are produced during the dull days of winter when but few things are in bloom out of doors. It is at Christmas time and in the New Year that their flowers are in most request for decorations. To ensure having pure white flowers the plants must be covered with a frame or hand-light when growing, or be lifted and potted up and placed in frames or the greenhouse.

The flowers of the type when well grown measure 3 inches across, and are borne on stout, erect stems thrown well above the dark green leafage. *H. N. maximus* bears larger flowers, and is well adapted for forming a succession to the above-named. Quite as good results come from leaving the plants in the ground merely by placing a hand-light or frame over them and covering this with litter or mats at night and on frosty or rainy days. Many people, however, prefer to pot up the plants, as then they can be utilised in the conservatory or in dwelling rooms when in blossom. Early in spring these should be replanted into deeply dug and well-enriched soil on a warm border, where they should remain for one or two years undisturbed before again being lifted. Abundance of well-developed flowers

cannot be expected two years in succession from the same plants. Those who are fortunate in having a good stock of established plants can lift a batch each year, and these can be brought on into flower as required. By planting out and giving liberal treatment throughout their season of growth they may again be lifted and gently forced in the second year. Hard forcing must never be resorted to, or the results in after years will be disappointing. The production of flowers may be hastened by merely shaking a few tree leaves among the crowns, and then keep the frame close and dark for a few days. With regard to those potted up they should be plunged in a bed of tree leaves, as these afford just that gentle warmth that is natural and no harm will result to the plants. Essential points to bear in mind in the cultivation of the *Hellebores* are liberal treatment in summer, the proper ripening of the crowns in autumn, and, lastly, not to disturb their roots oftener than is absolutely necessary. H. T. M.

### HARDY FLOWERS FOR HOUSE DECORATION.

THE flowers of many hardy plants which once seemed to be despised have regained favour, and it is, indeed, fortunate that florists again use many which formerly were in great demand. Thus we may now see in the displays of the leading florists the panicles of the Goat's-beard, Meadowsweet, Poppies, Foxglove, Larkspur, Iris, Sunflowers, and many others which formerly appeared to be of no value, and were relegated to the shops of the smaller florists or to the buttonhole stalls of the boulevards, or withered under the sun in the carts of the street flower-hawkers. Grasses, the spikes of Wheat, Oats, Barley, &c., are also much used

RAMONDA PYRENAICA ON ROCK GARDEN.  
(From a photograph by Miss Willmott.)

in floral arrangements, and we owe much to those who first thought of using them in this way.

The flora of the garden is extensive enough to respond to the many exigencies of floral decoration. And if the flowers of early spring (except a few, amongst which are the large Tulips) are not always fit to be used in large displays, others succeed them whose qualities are well worth considering. Such is the Iris, especially the beautiful varieties of the hybrid German Irises, whose flowers with their tawny tints, soft shades, and delicate velvety petals almost rival the Orchids. Peonies, Delphiniums (which comprise the whole scale of blues), Chrysanthemums, and Sunflowers—all are suitable for the composition of elegant and effective arrangements. We have mentioned above perennials only, but neither are the flowers of annuals and biennials without advantages from the artistic point of view. Few flowers were more neglected by florists than the single Dahlias and Cactus Dahlias, yet with these very pretty effects can be obtained. The Belgian, German, and Dutch florists make great use of them, for they know the value from a decorative point of view of these Dahlias. These ought not, however, to be placed in stiff rows; they show much better if they are placed in bunches at different heights. If they are very pretty when thus used alone, they have an equally good effect when associated with flowers of another kind, whether it be with heavy clusters of Tritoma, or with the slender Montbretia or Gladiolus. There is something exquisite in the blending of the colours of the Tritoma, the Montbretia, the clusters of the red and orange-coloured fruits of the Elder tree, the Mountain Ash, and other red-fruited bushes. The German florists create some very pretty things in this style. The varieties with purple flowers will also produce the same effect when associated with Gladiolus of the same tone and with other flowers. Others are very beautiful when mingled with autumn-tinted foliage or placed among the branches of the Copper Beech or the variegated-leaved Acer Negundo.

This is not the place to enumerate all the hardy flowers capable of being utilised in floral arrangements, but we cannot too strongly call the attention of florists and amateurs to the numerous ones unjustly neglected. Wild flowers are also hardy flowers, but they are distinguished from the latter, inasmuch as they are not cultivated. In spite of the poetic ideas which they evoke, they cannot be used as much as one could wish, for they are deficient in certain necessary qualities. Nevertheless, one cannot dispute their decorative worth when mingled with the common grasses. This combination lends itself to the formation of exquisite bunches.

It is astonishing that the Parisian florists have not learned to use the Nymphaea in their floral designs. In order that they may show well, care should be taken to place them in an oblique or horizontal position rather than upright. If florists would use them intelligently they would find that some very pretty things could be formed with them. To say nothing of the flowers of Nymphaea alba, the flowers of the hybrid Nymphaeas, with their lovely tints of rose, sulphur, orange, violet-blue, &c., would offer special attraction. Nelumbium speciosum is also a very ornamental flower, and one that ought not to be left out; the long spikes of Willow form a good companion to it. Cherry and Apple branches in flower are used for home decoration, and rightly so; it is a great pity that the decorative value of trees and shrubs has not been recognised before. The long branches covered with snowy blossoms or tinged with the faintest touch of rose colour, and with plenty of dainty unopened buds, are superbly pretty when well disposed. There is nothing so delightful as these fresh blossoms; it is the orchard with all its perfumes and promises of spring which thus is brought into our homes. But the fruit-bearing trees need not be deprived of all their blossomed branches, for we have beautiful and purely ornamental varieties of Plum, Peach, and Quince, which every spring are covered with blossoms. Neither let us forget the series of beautiful ornamental Crabs, which deserve to be utilised more than they are in floral work, and which, after having pro-

duced innumerable flowers, are covered with myriads of small fruits. Florists have already recognised the beauty and value of the ornamental Cherries, but it would be praiseworthy if the majority understood better what use to make of them, following the example of the Japanese, who, as soon as Nature reawakes, adorn all their dwellings with blossom-covered shoots, and thus bid welcome to the spring.

ALBERT MAUMENE, id *Le Jardin*.

#### SAXIFRAGE DR. RAMSAY.

THIS Saxifrage, raised by Mr. Robert Lindsay, Kaines Lodge, Midlothian, promises to be one of the finest of the encrusted section. It has a large rosette of long leaves, and produces its flowers freely on good spikes. The individual flowers, which are white, are large and well formed. It is a plant which grows well, and seems likely to become a favourite when better known. The greater portion of the stock has been put in the hands of a nurseryman for distribution, so that it will probably be available before long.

S. ARNOTT.

#### EVERGREEN HOLLIES.

(Continued from page 93.)

##### ILEX INTEGRA.

**K**NOWN also in some gardens as *Othera japonica*, this distinct Holly is represented by a fine specimen in the Kew collection. It is of a shapely pyramidal growth, 15 feet high and 7 feet in diameter. The most marked character of the species, as a Holly, is the entire absence of spines on the leaf margins. The leaves are obovate or lanceolate, blunt pointed, 2 inches to 4 inches long, and of a lustrous dark green. Except possibly in the south and south-west of the British Isles it does not appear to bear fruit freely. In her late Majesty's garden at Osborne a specimen used to (perhaps does now) produce berries freely. These are red, about half an inch in diameter, and in Japan, where the tree grows 30 feet to 40 feet high, are said to make this Holly very ornamental. The species is a native of China as well as Japan, and besides the names given above is known also as *Ilex integrifolia*.

##### I. LATIFOLIA.

Although this magnificent Holly has stood outside in a sheltered spot at Kew for many years without injury, it really requires a warmer climate to develop its full beauty. Of all the Hollies that can be grown out of doors in the British Isles this is the finest as regards the foliage. Oblong in form, and of a deep lustrous green, the leaves frequently measure 8 inches in length and 4 inches in width. The margins are set with thin, but not sharp or spiny, teeth. It is a native of Japan, but occurs too far to the south of that Empire to be hardy in most parts of Britain. It reaches occasionally a stature of 60 feet, and is described as not only the most beautiful of all the Hollies of Japan, but the handsomest of all broad-leaved evergreens in that country. The fruit is large, like that of *I. integra*, scarlet, and produced in short axillary clusters.

##### I. OPACA (AMERICAN HOLLY).

Whilst not possessing the bright foliage that is so characteristic of our native Holly, nor being so beautiful a plant, the American Holly is, withal, a very handsome evergreen. At its best it reaches a stature of 40 feet to 50 feet, and has a trunk 2 feet to 3 feet in diameter. Its habit is much the same as that of the common Holly, being somewhat narrow and pyramidal. The leaves are very distinct from most Hollies in being smooth, but quite dull;

they are 2 inches to 3 inches long, the margins set with spiny teeth. The fruits are roundish, dull red, and about a quarter of an inch across. The species was introduced from the United States to Britain by the Duke of Argyll in 1744. Probably there are big specimens in the country, but I have not seen any myself approaching the heights given above, which are those of native trees. Of the several representatives in Kew the largest is about 25 feet high and 16 feet through. It would be interesting to know of any large specimens that may exist. It is easily distinguished from other Hollies of its size by the dull, "opaque" aspect of dark green foliage. No varieties of it appear to exist in cultivation, although Sargent states that its berries are sometimes, though rarely, yellow.

##### I. PERNYI.

The latest addition to evergreen Hollies, this species promises to be also one of the prettiest and most distinct. It is a native of China, and is now, I believe, cultivated by Messrs. Veitch in the Coombe Nursery, having been introduced by their collector, Mr. E. H. Wilson. It had previously been discovered by Dr. A. Henry and other travellers. The leaves are 1 inch to 1½ inches long, closely set upon the branches and short stalked. Each leaf is ovate-lanceolate in general outline, but has one or two (usually two) prominent spine-tipped teeth at each side, and has a long, tapering, sharp-pointed apex. The fruit is globose, red, and as large as that of the common Holly. This species has quite a different aspect to any other species of Holly, and resembles most, perhaps, some of the smallest-leaved varieties of *I. Aquifolium*. Its distribution by Messrs. Veitch will be awaited with interest.

W. J. BEAN.

(To be continued.)

## THE FRUIT GARDEN.

### MELONS AND THEIR CULTURE.

**F**EW fruits are more appreciated during the summer months than a ripe, luscious Melon, and those who wish to be able to enjoy them must not delay making preparations for their culture. It may be said that it does not pay to sow Melon seeds before Christmas, even for the earliest crop of fruits. I have tried sowing seeds in December and also in January for a first early crop, and my experience is that more satisfactory results are experienced from the latter sowing. In December, when dull and sunless days are the rule rather than the exception, the seeds take a long time to germinate, and the plants become weakly and attenuated, and even with the advent of brighter days in the spring never seem really to have the vigour of later-sown plants. Those sown, say, the second week in January, have the advantage of brighter weather and increased sunlight, and the seedlings show their appreciation of this by a rapid and vigorous growth. It is astonishing what a difference there is in the growth of seedlings in December and about three weeks later. Sometimes Melon seeds sown in December will produce ripe fruits a few days earlier than those sown in early January, but often the latter will give fruits at the same time, and they are superior in flavour and size. A good deal, of course, depends upon the weather and also the district in which the grower resides. In the neighbourhood of London, where the winter days are often unaccompanied by sunlight, and sometimes foggy, I have repeatedly known Melon seeds sown in January to develop into plants that fruited as soon as those from seed sown three weeks earlier. The Melon, however, is never appreciated early in the year; it is a fruit for a

hot summer's day, and then only attains to perfection. In the absence of sun the flavour can never be of the best, so that except under special circumstances Melon culture quite early in the year does not prove satisfactory.

Seeds sown now will produce ripe fruits in May and June; two seeds should be sown in a small pot that has been filled with loam with which some leaf-soil and sand are mixed. Place the pots close together in a warm house. Cover with a piece of glass; this keeps the soil moist and warm. Hasten germination when the seedlings have grown sufficiently to enable one to see which is the stronger of the two, and pull up the other one carefully, or, better still, cut it off at the base; the roots of the other then will not be disturbed. As the seedlings appear the glass must, of course, be removed. Keep them near to the roof glass, otherwise they will become attenuated. Melons always grow best upon a hot-bed, i.e., a bed made of manure and trodden firm. It should be made up quite a week before the Melons are to be planted, so as to allow it to settle somewhat and also to decline to a suitable temperature if, as often happens, this is too high and would be harmful to the roots. Upon the manure should be placed two layers of whole turves, grass sides downwards, making small mounds of rather fine soil along the centre. If the bottom-heat has declined to about 80° or 85° Fahr. it is quite safe to plant. With a trowel make holes in the small mounds of soil, and sufficiently deep to dig into the upper layer of turves. Turn the young plants carefully out of the pots and plant them, placing the fine soil close to the roots and making it firm. I have found that Melons grow much better in a comparatively small amount of soil than in a large bed. A bed two turves deep and three turves wide will grow an excellent crop of Melons, with the help of a little top-dressing of soil if the roots begin to show on the surface. Nothing appears to suit the Melon better than turves cut from a meadow, or if these cannot be had fibrous loam in as large lumps as possible. This plant dislikes loose, fine soil; it is important to make the bed firm.

Keep the Melon house warm and moist, both at night and during the day, and do not stop the plants until they reach the top of the trellis. Side shoots bearing male and female blooms will form naturally. Do not fertilise the latter as soon as one or two appear, but wait until four or five are open together, then fertilise all of them. In early summer a plant ought to be able to mature four good fruits, therefore allow this number to develop if possible. If one flower is fertilised the embryo fruit will develop rapidly at the expense of any others formed afterwards, and these will never make good fruits. It is important, therefore, to fertilise several blooms at the same time, and choose the fruits that appear to promise best. When three or four fruits are set and are developing quickly stop the shoots two or three joints beyond the fruits, and also stop at the first joint any sub-lateral shoots that will subsequently form. An important point in Melon culture is to obtain strong healthy leaves on the plants, and these will form very early in their growth. They never form a sub-lateral growth, but only on the laterals. The possession of these is half the battle towards obtaining healthy plants and good fruits. Never let the foliage become crowded. If the first leaves have developed properly there will be little room for sub-lateral growth; this, therefore, must be frequently stopped.

When the plants are in flower and when the fruit begins to show signs of colouring the atmosphere of the house should be kept rather drier. Give liquid manure to the plants when the fruits are developing, and cease doing so when they are

ripening; clear water, however, must still be given. It is a mistake to keep the bed of soil dry when the fruits are ripening, the roots are still alive and need nourishment. On the other hand, keep the atmosphere dry or the fruits may crack. An excellent method of suspending the fruits when they become so heavy as to need support is by means of pieces of fish netting tied to the trellis and enclosing the fruits.

The varieties of Melons now in commerce are legion, so I forbear to name any; most growers have their own favourites. A. P. H.

## THE FLOWER GARDEN.

### THE WHITE PINK AS AN EDGING.

THE accompanying illustration shows the beauty of a border when it is margined with Pinks. Any hard edging in this instance would have spoilt the picture, and those who contemplate alterations now in the margin or actual formation of the border

in March and April, though from some cause they produced much less than the usual harvest of seeds; they scarcely had a period of rest during the past summer; they grew freely, putting in strong hearts to the plants, and it is not surprising to find that they have been constantly in flower since September last. I could gather handfuls of bloom at the present moment, though its beauty is marred by the weather. It does seem a pity that all this floral force should be spending itself in midwinter, it would be much more welcome in March and April, when, it is to be feared, there will be a dearth of it. If, as it is feared, the crowns of the plants formed last summer are spending their strength for nought, a scarcity of flowers from these crowns may be anticipated. We must look to the formation of new crowns in early spring to supply the floral effect in April and May.

In order to prevent as far as possible this abnormal winter bloom, I tried the experiment of lifting in October a number of plants which were replanted with little attempt at division, but with small effect on the production of bloom. The force was in the plant, and it found expression in bloom. Perhaps a spell of hard frost might have

AN EDGING OF THE OLD FRINGED WHITE PINK.

should remember the importance of massing together good things, with a careful sequence of colouring. Of all flowering plants the Pink is among the most satisfactory. Its drifts of blossom appear in June, and in the winter we get the full value of the silvery foliage, which is almost as precious as the blossom of summer. The old fringed white has almost gone out of cultivation, but I prefer it to the big-bloomed varieties such as Mrs. Sinkins. T.

### THE FLOWERING OF THE POLYANTHUS.

THE Polyanthus has had a flowering season extending over a whole year. The wet summer of 1902 encouraged a vigorous growth in the plants; they were deprived of their usual prolonged summer rest; they bloomed through the winter of 1902-3; they were in fairly good bloom

a deterrent effect, and yet it might only be a case of repressed energies certain to break forth again on mild weather following the frost.

I have had but very little autumn bloom indeed among Auriculas, but they, being always under glass, were not subjected to the conditions of weather experienced by the outdoor Polyanthus. They are already showing signs of movement in the direction of spring growth. In another month the most interesting season of the Auricula will have commenced, and it is a great advantage to have them in a house in preference to a cold frame, which can be opened only in fine weather. I am anticipating with great interest the blooming of a number of plants from seeds obtained from a semi-double variety. The double-flowered varieties are very few, and they are not recognised as a class by the National Auricula Society. Still they have a fascination for me, and I am doing my best to extend the number of double forms in cultivation. R. DEAN.

## GARDEN ORNAMENT.

## LEADWORK.

**I**N many of the fine gardens which surround our splendid old English country houses will be found decorating them with exceeding charm, superbly sculptured capitals of classical columns, sometimes wrongly, indeed generally so, called Italian "well-heads." The majority are usually described as coming from Venice, where, strange as it may seem, there are no wells, and consequently no "well-heads." Built upon piles and artificial stone mounds, Venice covers seventy-two islands or shoals, intersected in all directions by hundreds of salt water canals. Hence all the fresh water used for household purposes has to be caught in rainy weather from the heavens above in cisterns built on the Byzantine system. The mouths or openings of these cisterns are usually circular, and not infrequently elaborately sculptured, and some of these, the smaller ones, have been sold to enterprising foreigners, and set up in English and French gardens with good effect. The finest example still remaining is the noble one in the courtyard of the ex-monastery of San Sebastiano, by Sansovino, which has often been copied in various materials, from marble to copper, forming an admirable receptacle for very large plants.

Another fine example of this highly decorated cistern aperture will be found in the Campo San Giovanni e Paulo. It is richly decorated in the Renaissance style, with sporting *amorini* (cupids) and armorial bearings. Indeed, all over the wonderful city are to be found numerous circular and richly-sculptured "well-heads," as they are erroneously called, originals and copies of which are frequently met with in our more majestic gardens. A few of these have been designed to represent immense capitals of classical columns, such for instance as the two magnificent specimens which adorn

with such striking effect the lawns of Kingston Lacy. These are evidently genuine Venetian cistern-heads of the best period of the Renaissance, of the same class as the beautiful one by Sansovino at San Sebastiano, which is signed by his name.

Fresh drinking water was brought to Venice in former times from the mainland in feluccas, and sold about the streets by women who wore a very curious costume, exactly resembling that of the Welsh peasant lassies, consisting of a tall black felt hat, a short petticoat, and an apron. On their shoulders they carried a yoke like our old-fashioned London milkmaids, from the ends of which dangled two buckets. Many people who have not yet passed middle life can well remember their plaintive cry of *a'ò*, or water, fresh water! Modern improvement has swept them and their calling away, and now ugly leaden pipes of prodigious length which run along the railway viaduct, linking Venice to the continent, brings thence the supply of drinking water to the Queen of the Adriatic.

The Venetian cisterns, however, still remain, and their often elaborate decoration might easily be reproduced for decorative plant-pots, and introduced to break up the monotony of our lawns, even in comparatively homely gardens. It is, however, next door to a crime to tempt their owners to sell the originals. Has not Ruskin cursed anyone who removes a single stone from the most beautiful and romantic of cities?

All over Italy, a country rich in classical ruins, the capitals of columns will be found converted into flower-pots or pedestals for statues and sundials. During the long period of the Renaissance an amazing number of ruined temples and monuments were wantonly destroyed, and their materials used up in the decoration of churches and palaces. This was notably the case in Rome, where rows upon rows of beautiful columns, which had resisted the effect of time and the vandalism of the barbarians, were thrown down and carted off to adorn the 365 churches and basilicas of the capital of Catholicism. Their capitals were in many instances preserved, and turned to use as decorations for gardens and courtyards, when they were, for some reason or other, not required for the new purpose to which the columns they once crowned were devoted. The same thing occurred at Naples, and in the gardens of both cities beautiful Corinthian and composite capitals will often be noticed degraded into flower-pots and sundials. There were some magnificent specimens in the splendid Ludovici Gardens, which the cupidity of modern speculation has wantonly destroyed and replaced by streets of hideous jerry buildings. There was nothing in the world to equal the loveliness of these gardens, which were literally a continuation, so to speak, of those of Salust, whose site they occupied. Their secular umbrella Pines, their Ilex groves, and their stately architectural terraces, peopled, yet not crowded, with well-arranged statues, sundials, and column capitals, formed a unique *ensemble*, the delight of poet and painter, who alike haunted them, to enjoy not only their manifold beauties, but also

A CHISWICK VASE.

A LEADEN VASE AT CHISWICK HOUSE.

the glorious views of the Eternal City which they commanded. The wanton and greedy destruction of the Orti Ludovici was, together with the destruction and levelling to the earth of the Church of the Servi in Venice, the most monstrous act of vandalism committed in Italy last century.

The introduction of classical capitals of columns into garden architecture dates back in Italy to the beginning of the fifteenth century, and it is worthy of imitation, for the effect is admirable; the richly decorated capital resting upon the green sward, or rising from the centre of a group of natural Acanthus leaves, is charming, and if it be possible to chisel out a sufficiently large hole to insert a leafy plant it would be difficult to find a more graceful kind of vase. An equally delightful effect can be obtained in such fortunate gardens—and they are numerous—as contain the ruins of some Gothic abbey or priory, by converting the capitals of clustered columns to the same purpose.

At Walsingham Priory in Norfolk several noble capitals, whose columns have disappeared ages ago, have been turned into gigantic flower-pots, from which the tendrils of the Periwinkle, with its pale blue flowers, pour over in a graceful cascade of foliage and bloom, not concealing but displaying the time-worn sculpture to charming advantage. One masterpiece, representing an ancient marble tomb, presumably of Italian workmanship, but far more likely of the late Greek period, at the time of Alexander the Great, is in a garden in Somersetshire. This is a proof, if proof were needed, of the exceeding art wealth of the country. Surely it is more worthy of a museum than of a garden where it is exposed to the effects of our changeable climate.

The greatest care, however, must be exercised in the arrangement of these "well-heads" and

capitals be they Greek, Roman, Norman, or Gothic. They must appear to have come into position almost of their own accord, as if in the course of centuries they had discovered for themselves a new purpose to which to devote their grace and beauty. Any attempt at trimness destroys the picturesqueness of the effect they should produce, and it requires the eye of a true artist to select the exact spot where they should rest, amid surroundings exactly suited to their architecture and colour.

The introduction of anything architectural into a garden, especially an English garden, is matter for much thought. In certain places even a huge terra-cotta pot lends charm. A row of monster pots, with Orange and Lemon trees in them, in the old gardens of the Villa Lante at Frascati has been painted again and again by famous artists. They seem to have ranged themselves by some occult process, known only to themselves, to have grown up spontaneously in the vast beds of Violets, Pansies, and Verbena which surround them. The yellow of the crumbling wall behind them is rendered all the more vivid by their dull red. Between two of the largest you can obtain a never-to-be-forgotten view of the far-stretching Campagna and of distant Rome. A great artist, whose name is long since forgotten, placed those venerable terra-cotta pots in position some three hundred years ago. May they still stand where they are, with their treasures of deep emerald leaf and golden fruit, three centuries hence.

## THE CACTUS DAHLIA

AT HOME AND ABROAD.

**B**RITISH hybridists have practically held the monopoly of the output of new varieties of the Cactus Dahlia.

The interest this flower has awakened is phenomenal, not only in England, but in many other countries where the climate is anything but temperate. The home trade is now a very extensive one, and the interest taken in growing and competing bids fair shortly to equal that of the Chrysanthemum. In this respect the Scottish growers show as keen a desire to excel as the growers farther south, and from Wales also come very fine flowers and new varieties. Ireland, also, whilst not as yet to our knowledge contributing to the list of varie-

THE KNEELING SLAVE AT MELBOURNE.

ties, is yearly importing new varieties from England in increasing quantities. Leaving the British Isles we find our near friends the Dutch keenly alive to the necessity of raising new and improved varieties in order to compete with the English.

Every year many Dutch firms import largely from England, and offer in exchange varieties of their own raising. As yet, however, the growing of Dutch flowers is not general here, although a few sorts have been catalogued, a notable feature

of the Dutch flowers we have seen being the colours, which were of soft and pleasing tints. Scarcely behind the Dutch follow the German and Belgian growers, Germany producing a large number of new flowers; and yearly we receive offers to exchange novelty for novelty, but firmly declined on our part.

Probably next to Holland Germany is the largest buyer of new flowers from England. Belgium is naturally allied to Holland as regards the Dahlia, and so we go on to Italy, where the fever is just beginning to rage, as also in Sweden, and in a minor degree other Continental countries. We had almost forgotten France; but here there are quite strongholds of Dahlia growers, and the old offers to exchange novelties are repeated. Several French sorts of the decorative type have found their way to England. The growing of the old decorative form still seems to thrive in France, and few, if any, new flowers of the Cactus type have been catalogued by English raisers. The growers of France are evenly scattered from Paris to the Mediterranean Sea, and the culture of the Dahlia is evidently a feature with several prominent nurserymen.

To come to our Colonies, India is trying the Dahlia, roots having gone to Calcutta and Bombay, and, if reports are true, succeeded well, as also in Malta and Egypt on the coast. It is, however, in Tasmania, Australia, and New Zealand that the Dahlia is appreciated to its fullest extent. The number of amateur enthusiasts there is considerable, and every year shows are held as in England, where the Dahlia figures largely and excites considerable competition.

The amateur growers import the new flowers every autumn quite as largely as the nurserymen, and the English gardening papers are studied to watch the strides made in raising new flowers from these regions. Until now there has not been any great importation of Colonial varieties by the English growers, although one or two raisers of Australia and Tasmania have made considerable progress in that direction. Altogether, the trade with the Colonies is a pleasant one, the striking feature in all dealings with our colonists being the straightforward manner in which they transact business, interesting letters coming to hand every year from growers in the Antipodes, where, for the comfort of English gardeners, we might mention that there are numerous enemies to fight and many disappointments.

From Cape Town to the Transvaal capital there are Dahlia growers, not so advanced as the Australian as regards shows, &c., perhaps, but still the Dahlia is there, and is greatly on the increase, a recent member of the National Dahlia Society only to-day turning up (by letter, of course) at Pretoria, asking for the Dahlia. Poor fellow! probably he was homesick, and the sight of a Cactus Dahlia in his garden would encourage him. He was a grower of the best in England, and we hope to send him a comforter in the shape of a dozen and a-half of Britain's best.

We have now travelled over a good portion of the Globe, and will wander back north-west to America, notably the United States. Unless we are much mistaken, the Canadians are too busy growing into a nation to think of Dahlias to the extent they ought, but dotted here and there are growers who import yearly. It is, however, in the States that interest in the Dahlia becomes more apparent.

As to exhibiting, we have no very definite news to hand of this in America; but no doubt they have Dahlia classes generally, and we know of one grower who carried off all the prizes in the classes open to him, some eight in number, including prizes of considerable value at one show. The American raiser is not yet noticeably to the front, unless the varieties never find their way to England, which is surprising.

In closing these few notes on the Dahlia, we should like to mention that with few exceptions it has been our lot to receive the most friendly and pleasant letters from Cactus Dahlia growers all over the world, and, in fact, it has often surprised us to find so general and pleasant a tone, not only

from colonists, but foreign growers as well. Possibly the Cactus Dahlia exerts a softening influence both at home and abroad.

Berkshire.

## GARDENING OF THE WEEK.

### INDOOR GARDEN.

#### TABLE PLANTS.

WITH the difficulty of providing such plants for use during autumn and winter every gardener will be well enough acquainted; but his anxiety does not stop here, for annually there is a growing demand for flowering plants for this particular purpose. True, it is difficult to dispense absolutely with the use of ornamental foliage plants, and many of these when well grown are very handsome. Of these perhaps Crotons, Pandanus, and Dracænas are generally used, but to render them favourites they require to be well grown, and the foliage highly coloured. Early propagation is advised as the secret of having them in proper condition for use by the coming autumn, and although the propagation of Crotons was advised at the beginning of the year, there is yet time to propagate and to grow the whole of these plants into good specimens by the time mentioned. Among flowering plants Begonia Gloire de Lorraine is one of the most useful. Small plants are the best for table requirements; commence propagating them at once by selecting good sucker shoots for cuttings. Insert these singly in 2½-inch pots in fine leaf-soil and sand, or obtain and dibble among sand a few of the leaves that are free from disease, and with the entire length of the petioles attached; plunge the pots in a bottom-heat of 65° to 70°, and maintain a moist atmosphere. Gesneras, the new hybrids, can be raised from seeds, which, if sown at once, will produce by the autumn plants that will be admirable for any purpose, especially for table decoration. Cyclamens for this purpose require careful attention. A few of the corms should be grown on a second year, as these usually grow into bigger plants and produce more flowers. Sow at once a few seeds of Primulas, especially the stellata varieties, as these when well grown and flowered make beautiful plants for the table. Other plants valuable for the purpose are Azaleas of the amæna type, together with Erica hyemalis and E. gracilis autumnalis.

#### ACHIMENES.

The tubers, which during the winter have been dormant, should be overhauled and selected for immediate repotting into fresh soil. Leaf-soil, peat, a little dried cow manure, and sand form a compost that suits them well; but during the growing period they require to be shaded from strong sunlight, and with regard to heat and moisture to be liberally treated.

#### GARDENIAS.

These keep in a healthy condition by keeping them free of mealy bug as well as green fly and thrips; and this is not difficult if occasionally they are syringed with Bentley's Insecticide or with paraffin, one tablespoonful to every gallon of water. If they are planted out remove a portion of the surface soil and top-dress with fresh loam, wood ashes, and dried cow or sheep manure, those in small pots being shifted into larger ones as they require it. Cuttings, as soon as they can be obtained, should be inserted in pots, and the latter plunged in the propagating bed; another plan is to place narrow boxes, about 8 inches deep, on the top of the hot-water pipes. Fill these to about half their depth with broken pots for drainage, then a layer of Moss, and finally about 2 inches of sand in which to insert cuttings of the half-ripened shoots.

#### ANTHURIUMS.

These greatly dislike sour material about their roots. They should be repotted annually, or resurfaced with a compost of good fibrous peat, lumpy loam, sphagnum moss, and a few broken

crocks. The plants during the growing season delight in a moisture-laden atmosphere, with a temperature of 65° to 70°. J. P. LEADBETTER.  
The Gardens, Tranby Croft, Hull.

## FLOWER GARDEN.

### EDGINGS.

THE character of the edging depends largely on the surroundings. Where a formal edging is needed Box is one of the best evergreens that can be used; but to look well the blanks must be kept filled up, and during the summer clipping must be regularly attended to. The present is a very good time to make a new edging. A nice bordering may be made of flints or pieces of granite laid so that the outer edges are in a fairly straight line, and sinking the stones sufficient to prevent them from being easily displaced. Stones that are found locally are usually more in keeping with the surroundings than imported ones, and the former become quickly covered with moss and lichen. In the crevices between the stones many alpine plants will find just the conditions essential for their well-being, and many will quickly ramble over the stones and out into the path, breaking in a delightful manner the formality of the edging.

Aubrietia deltoidea and its varieties make a very pretty edging. Where it thrives the blue Gentiana acaulis is very striking. In many cottage gardens one sees a double bordering of Thrift, sometimes nearly a foot in width. Mrs. Sinkin Pink, the double Daisies, Arabis, and many others are also beautiful and useful for this purpose. But whatever is used the ground must first be properly prepared or the edging will never be in a satisfactory condition. The soil should be well worked, raked, and made firm.

### BEDDING PLANTS.

Pelargoniums (Geraniums) which were struck in pots or boxes last autumn will now require to be potted singly or boxed; where possible the first method is preferable, but if a good layer of spent Mushroom bed manure, or something similar, is first placed in the bottom and the remaining soil is fairly "rough," good results may be obtained from boxes. A light syringing twice or three times on bright days will prevent flagging. Standard Fuchsias, Heliotropes, &c., that have wintered cool should now be pruned and brought into a warm house.

Insert the necessary cuttings of such as Iresine, Alternanthera, Ageratum, Heliotrope, Coleus Verschaffeltii, and place in a brisk bottom-heat.

### SOWING GRASS SEED.

If it is intended to sow any lawn grass seed the ground should now be thoroughly prepared—good digging is as necessary for grass as for herbaceous plants, choosing only fine days and when the soil is in a good workable condition. The date of sowing will vary, according to the locality, from the end of this month to the latter part of April. The soil must be made firm and well worked, keeping the surface level and to the full height of the lawn. If it is possible to lay a row of turves around the outsides, this will be found a good guide in keeping the remainder level. When sowing choose a fine still day, and sow as evenly as possible, using the best quality seed procurable, and lightly cover it with a wooden rake. When the grass is well up it will be advisable to roll with a heavy roller before cutting, which should be done with a sharp scythe.

A. C. BARTLETT.

Pencarrow Gardens, Bodmin.

## KITCHEN GARDEN.

### EDGINGS.

THIS is a good time to set about the repair or renewal of edgings. Where they have become rather thin the best plan is to clear out a good length and renew entirely. Before relaying the part to be operated upon should receive a dressing of good turfy loam, for where edgings have stood for several years the soil will have become exhausted. A fine dry day must be chosen for this work, as the soil must be well beaten and trodden to the proper level. Care must be taken

that the trench is cut to the exact width of the path. The Box plants should be pulled into single roots and shortened to 4 inches long, and laid thinly and evenly, making them firm at the roots as the work proceeds.

If the walk has become soft and much soil mixed with the gravel it should be cleared away to the depth of several inches and a fresh coating put on. After the whole work has been completed frequent rolling will be beneficial. An inspection of all garden paths should be made, and where repair is needed this is a good time to begin, before the busy season is with us. An effort should be made to give all walks a sprinkling of new gravel every spring. A good layer of ashes between garden plots where there is much traffic will be found a great advantage in wet weather.

POTATOES IN POTS

that were placed in a heated vinery early in January will now have made good growth, and should be removed to a slightly cooler house. A sprinkling of some good artificial manure may be given previous to earthing up. For the latter good turfy soil is required to which has been added a little leaf-soil. Fill the pots well up with the compost, making the soil moderately firm, and place them as near to the glass as possible.

EARLY PEAS IN POTS

are now growing freely, and short stakes will soon be required. They may be thinned out now to six or eight plants and grown cool and hardy. Onions, Leeks, Cauliflower, and other seedlings under glass must be carefully attended to, and on no account allowed to become drawn. Stand the pot or boxes close to the glass and water sparingly. On a south border or other warm corner the sowing of early Cabbage, Cauliflower, and Lettuce may be made. Protection must be afforded either by a thick covering of Spruce branches or a few hand-lights placed over them will be sufficient.

SHALLOTS.

Where the weather is favourable and the ground in condition these may be planted. The bulbs may be planted 3 inches deep to begin with, as they are liable to grow out of the soil. The soil may be drawn back from the bulbs after they have taken hold. Plant on a deeply-trenched and well-manured border.

THOMAS HAY.

Hopetoun House Gardens, N.B.

FRUIT GARDEN.

EARLY VINES.

THESE will now have the fruit set, and the sooner the bunches of free-setting varieties are thinned the better. Remove all badly set and ill-shaped bunches, and secure a full crop of medium-sized ones, leaving one only on a shoot. Pay daily attention to tying down shoots and stopping laterals. Pinch out the points of the shoots at the second or third leaf beyond the bunch, and all laterals at the first leaf. Avoid overcrowding, as the best leaves must be fully exposed to light and air.

Give a sprinkling of Thompson's Vine Manure after the Grapes are thinned, and water with tepid water. Keep the night temperature at 65° to 68°, falling 5° on cold mornings, and 75° to 80° by day with sun-heat. Close the house early, damping the paths and walls, care being taken not to damp the pipes when hot. Ventilation must also be

BEGONIA GLOIRE DE LORRAINE IN THE GARDENS OF COLONEL WILKINSON, ASHFURLONG HALL, SUTTON COLDFIELD.

carried out carefully at this season, always avoiding cold draughts.

EARLY MUSCATS.

These Vines, which were started early in December, will soon be in flower. Increase the temperature to 68° or 70° at night, 80° by day, with a further rise of 10° on bright days. The atmosphere must be rather drier when the Vines are in flower, and also keep the points of the bunches up to the light. A supply of Black Hamburgh pollen should be saved if possible to fertilise the Muscat flowers, doing this with a camel's hair brush; also run the hand lightly down the bunches. Close the house early, give air early also, as by liberal ventilation a strong healthy foliage will be secured that will stand the early summer sun without scorching.

SUCCESSION VINERIES.

The Vines in these will now be breaking into growth, and should be syringed with tepid water two or three times daily in bright weather until the bunches show, when direct syringing should be discontinued. Remove the weakest shoots gradually as soon as it can be seen which bear the best bunches. Keep a temperature of 55° to 58° at night, and 65° to 70° by day. Close the house early on bright days. Damp the paths once or twice weekly at closing time with weak liquid manure.

LATE VINERIES.

If Gros Colmar and Lady Downe's Seedling occupy the greater part of the house it must now be closed, so that the Vines may have the benefit of the best season of the year to complete their growth. Generally speaking, the two varieties above are the most popular late Grapes, and require a long season of growth; they also finish better when started early than by using extra fire-heat in the autumn. Appley Towers is a splendid keeping late Grape, which requires plenty of space. Mrs. Pearson can also be strongly recommended as a second white; it will keep for months when bottled in good condition. See that the border is watered,

if dry, with tepid water. A temperature of 50° at night and 65° by day from sun-heat will be suitable.

Impney Gardens, Droitwich. F. JORDAN.

THE INDOOR GARDEN.

BEGONIA GLOIRE DE LORRAINE.

NO warm greenhouse in winter is now considered to be properly furnished unless it can show a display of this Begonia, whose rapid leap into popularity has been most remarkable. A few years ago no one had heard of it, to-day it is difficult to find a garden where it is not grown. The accompanying illustration shows what a wealth of blossom a group of this plant will produce. It is a display that could be equalled by few, if any, other winter-flowering plants, and reflects greatly to the credit of the grower's skill. Begonia Gloire de Lorraine is one of those plants which if grown well is a delight to all, both cultivator and visitor, but if one only partially succeeds with it, then it is indeed disappointing. H. T.

NERINES.

WHEN a grower has mastered the cultivation of a class of plants he turns his attention to their improvement, either by prolonging the flowering season or increasing the size of flowers and improving the plant generally. To reach the object he has in view can only be obtained by hybridising, and to growers of the beautiful autumnal-blooming Nerines I would say select and hybridise, and by so doing increase the stock of your plants. Nerines are very prolific seed producers. Mr. O'Brien, when manager at Messrs. Henderson and Sons,

raised many Nerine varieties, among them being the beautiful Manselli, atro-sanguinea, and others.

M. Leichtlin of Baden-Baden raised from seed N. Novelty, a very free-flowering hybrid, by fertilising pudica with the crimson-coloured corusca. He also raised N. tardiflora and its variety major, which are almost equal to Manselli. Mr. Elwes, who has a collection of over 1,000 pots, has also raised many beautiful varieties, some receiving first-class certificates and awards of merit, the latest to receive this distinction being N. Miss Carrington. Mr. Moore of Glasnevin has also done good work in breeding and perfecting this race of plants.

No difficulty need be experienced in obtaining seed, which should be sown directly after being taken from the plant. Sow in pots, using a good porous compost of three parts loam, one part leaf-mould, adding some sand. Place the seed evenly in the pots and cover slightly with sand. The seed is generally slow in germinating, but this difficulty would be surmounted by placing on a shelf in the stove, removing the seedlings as they advance to an intermediate temperature. Here they would grow freely without shade for the first six months. Then they should be transferred to pans and kept in the same temperature.

The growth of the plants is somewhat rapid, no season of rest being required until the bulbs reach flowering size, which would be about three years from the sowing of the seed. After this long period of growth the bulbs should be allowed to rest. This rest consists of entirely withholding water, and plunging them in a frame where they are fully exposed to the sun and are subjected to a thorough baking. "They are so difficult to flower," is what we hear from the majority of growers. To those I respond, "Give them a fair treatment when growing, a fair season of rest, and then you should not be disappointed." The following particulars on the treatment of the bulbs' flowering size may be interesting to readers of THE GARDEN.

When the plants go to rest, about the month of April, they are plunged in a frame, water being altogether withheld and the lights taken off at every opportunity. Here they remain until the month of August, when they are overhauled and all re-potting done that is necessary, shaking every particle of soil from the roots. Activity at the roots will be apparent even at this early date, and this necessitates careful potting. Some growers wait until the plants are out of flower before re-potting, but great injury to the plants is caused by this practice, as the roots are then in an advanced stage of growth. After re-potting in such a compost as the one recommended for seedlings they are again placed in the frame, where they remain until showing flower.

They are then taken out, allowed to stand in a pan of water to get thoroughly soaked, and placed on a shelf in the greenhouse where they receive plenty of light, and the flower-spikes should develop to perfection. After flowering they should not be placed in a dark corner of the house, but on the shelf in full sunlight, and be treated as ordinary greenhouse plants, with an occasional dose of weak liquid manure. That is the treatment as afforded the plants at Colesbourne, the essentials of which may be summed up thus: Firm potting, a good season of growth, clean plants, and a long rest.

W. H. WALTERS.

Colesbourne Park, Gloucestershire.

## CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

### MODERN POTATOES.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—I notice that Mr. Wythes, in his article on some of the newer vegetables for 1904, page 63, confines his Potato references to a somewhat limited few of which he has had experience. As it happens, however, there is a number of high-class varieties in the market just now that are certainly preferable to the older sorts mentioned by your correspondent, such as Satisfaction and Reliance, and in view of this fact, also bearing in mind that seed tubers are now being obtained and prepared for spring planting, I venture to call attention to several modern Potatoes that are well worth growing.

The fabulous prices paid for a few sensational novelties do not interest me, and, like Mr. Wythes, I know nothing of the eating qualities of either Northern Star or Eldorado, because I have never met a man yet with courage enough to boil one, and it must be remembered that Discovery, about the table qualities of which Mr. Wythes speaks highly, is not a food commodity at twenty shillings a pound for seed sets. I recently heard of a case of a man who became acquainted with the flavour of Northern Star in a manner that was supposed to upset his digestive organs afterwards. He purchased a pound or two of seed tubers at a ruinous price, and foolishly left them on a shelf in the kitchen. His better half, who knew nothing of Northern Star or other gold mine Potato, cooked them without thinking, and—but perhaps it is well to draw a kindly veil over the rest of the story.

Turning to the varieties that are of proved merit, and may be obtained at reasonable cost, I notice Mr. Wythes speaks well of Ringleader and Ninety-fold in the way of first earlies. They both did well with me last year in the way of crop, but, strange to say, when I came to lift the main portion which I left to ripen I found three parts of the tubers of Ninety-fold affected by disease, but the Ringleader was practically free from it. The decision I have naturally arrived at is that Ninety-fold is more liable to disease than Ringleader, and consequently the latter is the best variety to grow. Speaking of early Potatoes, mention must be made of that splendid modern variety, Sir John Llewelyn, which has now had an extended trial, and is spoken well of in all quarters. Duke of York, an older Potato, holds its own as one of the best of the first earlies, and being of strong free habit it succeeds well in places where varieties of more tender constitution are apt to fail.

With reference to midseason and main crop Potatoes, I observe that Mr. Wythes can only speak of Evergood from hearsay, as he has not grown it. After an experience of two seasons, I am of opinion that this is one of the best of the new main crop Potatoes, and well worth a trial by any who are as yet unacquainted with it. The tubers are roundish, white-skinned, and shallow-eyed, and the variety has disease-resisting qualities.

It is not often that a good coloured Potato is put on the market, but I think we have one now that will take the place of the well-known Beauty of Hebron, which has deteriorated of recent years. The variety in question is King Edward VII., a pretty white kidney with flushes of pink round the eyes. It is a heavy cropper, a disease resister, and, unlike the majority of coloured Potatoes, it possesses capital eating qualities.

About three years ago Messrs Dobbie and Co. introduced The Factor, which is now getting widely known, and is well worth growing. It is a white, oval-shaped Potato of good form and excellent quality; it is a strong, robust grower, and wants plenty of room, but it is a splendid cropper, and one of the best of modern main crop potatoes. So far as disease is concerned, I had no trace of it amongst tubers of this variety last year.

Chiswick Favourite, a white, round Potato, introduced by Messrs. J. Veitch and Sons a few years ago, does not appear to be grown to the extent that its merits deserve, as it is amongst the best of the main crop varieties. In the early days of its history Chiswick Favourite received a first-class certificate from the Royal Horticultural Society, and events have proved that the honour was not misplaced. I can strongly recommend it to anyone on the look out for a good main crop Potato. It is very vigorous, but not unduly gross. Other modern Potatoes well worth attention are Royal Kidney, a second early variety, introduced in 1901; the Crofter, which came out in 1898; and Cigarette, a very handsome round Potato. Others might be mentioned, but I have said enough to show that there is no lack of choice amongst comparatively new Potatoes without considering any high-priced sensational novelties. If any excuse is wanted for urging the culture of these modern Potatoes I offer it in the fact that, apart from being good croppers and of superior qualities, they do not suffer from disease to anything like the extent that varieties do which have been many years in cultivation. The secret of this may be that the constitutions of strong modern Potatoes are as yet unimpaired, and consequently they are able to repel the attacks of disease. I do not claim for any Potato, including even the famous Northern Star, that it is perfectly disease-resisting, but while a variety is new and strong it is not so liable to attack as when its constitution is worn down by years of cultivation.

G. H. H.

### APPLE NORTHERN SPY.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—In reply to "W. S.," enquiring about this variety, I can say that it does very well in the South as a bush. It is an upright grower, and the branches should be regulated so as to expose the fruits well to light and air, otherwise the delicate colouring, which so much enhances the value as a dessert Apple, will be lost. It is a moderate cropper, but of excellent quality, sweet, crisp, and juicy. As it is in season from January to April, it deserves to be widely grown. In cold soils and situations it will well repay the protection of a wall. Another point in its favour is immunity from American blight.

W. CAMM.

The Gardens, Ashby Saint Ledgers, Rugby.

### THE GARDENING CHARITIES.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—When reading your able leading article in the issue of the 30th ult. it occurred to me that it should be the means of securing many readers, and especially gardeners, to become subscribers. Being a member, I am deeply interested in its welfare, and every year, when the election comes round, I look over the list to see the names of those who have become candidates, to find frequently the names of those I little expected to see; also to note the names of many that have applied three, four, and sometimes five years—and then are not successful—added to this ever-increasing numbers. If this continues at the same rate for the next twenty years it seems difficult to realise what portion will be successful then, seeing the large number that could not be put on in 1904. According to your statement, it shows how few do anything to assist it, compared to those who could did they so wish. It should be made plain that those who do not contribute to its funds have only a poor prospect should they need it, seeing those that have contributed a long time have a large number of votes to start with. I consider this is as it should be, and should be a great impetus to young men to join.

I am pleased to learn that an extended effort is about to be made to diffuse knowledge respecting its working, and by trade houses allowing a leaflet to appear in their catalogues. Recently, when lecturing at one of the mutual societies, I was astonished to find comparatively no one who knew anything of its working and benefits. "R. D." in a recent issue stated he had brought the charities

before the members of mutual societies. I did the same a few weeks ago, and at the close I was told that a gentleman in the room would have started it by giving 10s. The committee promised to see what could be done at the next meeting. I am convinced much help may be given to this and the Gardeners' Orphan Fund if the members of the mutual societies would start by having a collection day three or four times a year. Surely no member would refuse to contribute something. It may be said many could not afford to do much. Let us take a lesson from the small sums given to other charities, and note the amounts raised in this way. Added to this the Gardeners' Benevolent Institution offers advantages to subscribers if they raise £10 10s. in one year. What greater thanks could a society give to a member that had done good service than by placing him amongst the life members? J. CROOK.

## NURSERY GARDENS.

MESSRS. HILL AND SONS, LOWER EDMONTON.

**A**T the present time the Barrowfield Nursery is devoted almost entirely to Fern culture. Not only are the market sorts grown in almost countless numbers, but great attention is paid to the culture of all the choicer sorts, and the collection is one of the most complete to be

found. The nursery was first started about sixty years ago by the late Mr. J. Hill, who died about two years ago at the age of eighty-one. Mr. J. E. Hill, his son, who continues to carry on the nursery, started with his father at an early age, when Carnations, Pinks, Auriculas, Violas, and other plants were grown. About seventeen years ago Fern growing was started, but the elder Mr. Hill did not favour this innovation. However, the son prevailed, and, as at that time the markets were good, it was soon found to be a profitable departure, and from a very modest beginning this branch has steadily developed. New houses have been added from time to time, until now the nursery land is nearly covered with glass, and Mr. Hill has been singularly successful in the raising and cultivation of Ferns. The splendid exhibits which he has made during the past six years have given proof of the best culture. Mr. Hill is a firm believer in keeping a low temperature during the autumn and winter, finding that Ferns so treated start with much more vigour early in the spring, when a higher temperature may be given with advantage.

At the time of our visit—January 12—it was not the most favourable season to see Ferns, but we found much of interest. A most interesting corner was that devoted to a number of Ferns recently imported from Brazil; these included some very distinct things—a *Pteris* which at first sight appeared a little like *P. umbrosa*, but with more fleshy fronds; they were divided in three frondlets, somewhat after *P. tripartita*. Another might be a

narrow-fronded form of *Asplenium Nidus*, but, not being fertile, we could not determine. Several other pretty things were seen in this batch, some of which may prove to be species not hitherto in cultivation. *Platynerium* are a speciality, and a fine specimen of *P. grande* was noted. *P. Hilli*, *P. Veitchi*, *P. aethiopicum*, and *P. angolense* were also seen in good condition. Of Tree Ferns, *Dicksonia antarctica* is extensively grown, and was seen in all sizes from small seedlings to large specimens, with good stems, all of which were raised in the nursery. Of *Alsophila australis*, in large plants, and *Brainea insignis*, which until a few years ago was a very rare Fern, Mr. Hill now has large quantities in various sizes. *Lomaria attenuata*, remarkable for the bright rose tint in the young fronds, is well grown. *Davallias* are quite a feature, and include such choice sorts as *D. aculeata*, *D. epiphylla*, *D. Veitchi*, *D. assamica* (a most distinct and beautiful species of recent introduction), *D. repens*, and many others, the pretty little *D. parvula* and *D. alpina*, and, lastly, a fine batch of seedling plants of the beautiful *D. pallida* (mooreana). *Acrostichum crinitum*, *Gymnogramma schizophylla gloriosa* and the distinct *G. caudiformis*, and *Nephrolepis Fosteri* (a new American Fern, a little variable, but in its best form most distinct and attractive) were others.

A few of the best *Gleichenias* are very successfully grown. Fine specimens of *G. dicarpa longipinnata*, *G. flabellata*, *G. semivestita*, and *G. rupestris glaucescens* were seen. In addition to the ordinary market sorts of *Pteris*, many others are grown, namely, *P. tricolor*, *P. aspericaulis*, *P. nemoralis variegata*, *P. Victoriae*, and *P. Reginae cristata*. The doryopteris section included *Ludens*, *Duvali*, *sagittata*, and *pedata*. At the time of our visit *Adiantums* were not at their best, but it was noted that the collection, which includes upwards of 100 species and varieties, represented all the best sorts. Several Ferns which are rarely seen in large quantities have been successfully raised by Mr. Hill. Among these we noted large batches of *Osmunda javanica*, *Todea arborea*, and *Asplenium lucidum*. These are all very useful Ferns in a small state.

*Asplenium Nidus* is a great favourite with Mr. Hill, and he was one of the first to take it to market in quantities, and has always kept up a regular succession. It is in a small state that it sells best, but it is also grown on into 4½-inch pots and onwards, some making very fine specimens. I may here refer to a most distinct variety which Mr. Hill has selected and named *A. Nidus corrugatus*; it has fronds of remarkable substance, and they are distinctly corrugated. If this can be perpetuated it will supersede the older form as a market plant. *Polypodium aureum* is grown extensively, some large plants in 6-inch pots being extra good. Here, again, we find a distinct variety having the beautiful soft hue of *P. glaucum* and the vigour and large fronds of *P. aureum*; the fronds also have a good drooping habit. *Pteris major* is now the most popular of all this family, and is grown in very large quantities. *P. trenula* is also a favourite. *P. Wimsetti* is grown, but may be superseded by *P. Wimsetti multiceps*, a variety for which Mr. Hill gained an award of merit in 1892, and which has since been found to make a good market Fern. *Nephrolepis cordata compacta*, *N. tuberosa*, and *N. exaltata* are extensively grown for market. *Davallia decora*, *D. dissecta*, and *D.*

GYMNOGRAMMA SCHIZOPHYLLA GLORIOSA IN BASKET.

bullata may be included with those grown for market, for, though not raised in such large quantities, they sell well at a good price.

Among other plants grown *Aspidistras* occupy one large house, many of the plants being well furnished with beautifully variegated leaves. *Ficus radicans variegata* is grown in quantities, but this has not proved quite such a good market plant as was anticipated. *Ficus repens* is always in demand; the shelves in several houses were filled with well-furnished plants, and Mr. Hill has a good variegated variety of this, which may prove more useful than *F. radicans variegata*. Mr. Hill also grows zonal *Pelargoniums* in large quantities both in 4½-inch and 3-inch pots. A. HEMSLEY.

## THE KITCHEN GARDEN.

### A VALUABLE EARLY POTATO.

SUTTON'S MAY QUEEN.

**W**HEN one notes the increased interest in Potatoes generally it may not be out of place to write about the good qualities of those that have proved valuable, and though May Queen is a new variety, after a severe trial last season it proved a decided acquisition. This variety was shown at the last Temple show of the Royal Horticultural Society, and attracted attention for its perfect shape and beautiful flesh; but the true test of any variety is its flavour or good eating quality, though tubers dug late in May or early June cannot compare with those better matured; May Queen was of excellent quality, and far exceeded my expectations considering the unfavourable season. For forcing under glass it is specially good, and the tubers grown thus were dry when cooked, and they matured more quickly than the Ashleaf. This is a white kidney, and it is more valuable, as it builds up in a short time a fair crop of usable tubers, and there is an absence of small ones. This is a great gain in a forcing Potato or for early borders in the open. Planted in February at the foot of a south wall, and the haulm covered with dry litter to protect from frost, we lifted tubers at the end of May, and quite a month earlier in cold frames planted in January. For pot culture it is most suitable owing to its dwarf top. This, of course, is equally valuable for frames, and when its good properties are better known it will become a great favourite. G. WYTHES.

### PEAS FROM MAY TILL OCTOBER.

EARLIEST SEASON AND VARIETY.

In the open ground the earliest crops should be sown in February, as soon as the soil is in workable condition, and in the south, if an early variety is sown, there will be a late May supply. The Pea is much harder than many think. I have noticed the blossoms resist frost if dry. I admit there are exceptions. For instance, when the plants are raised in heat and planted out the haulm at times is so weak that any sudden change of weather results in collapse.

FIRST DIVISION.

In sowing the first earlies a warm and well-drained border should be selected with a light top-soil, and in heavy clay land it well repays the grower to make the soil lighter by adding such materials as fine mortar rubble, charcoal, and burnt refuse and wood ashes. With regard to the variety for this work, I do not advise the true Marrows, especially in heavy soil or exposed positions. There are some splendid selections, as of late years there have been immense strides taken in the selection and crossing to get hardness with a free crop and quality combined. Even now one sees some very old forms of small round white Peas recommended in catalogues, but I do not think they are worth sowing. By this remark it must not be thought because things are new I regard them as necessarily superior. Why I object to the true Marrows for first sowing is that the seed is more sensitive to cold and moisture, and unless the soil is sufficiently warm to promote

growth the seed does not remain stationary, but decays, and the crop is lost. It is difficult to make up for lost time. The earliest sorts are mostly dwarf, and there is this advantage, that the plants can be grown closer together. Some require very little support, but I find even the very dwarf Peas are better if the haulm is kept clear of the soil, and it is an easy matter to give the plants support. For first sowing no one will regret giving Chelsea Gem a trial. This has now stood for some years the test, and it is one of the best of the dwarf early Peas; it is so well known that I need not describe it, but, being about 18 inches high, it can be grown close together. The pods are mostly produced in pairs, and are of excellent quality. There is a more recent introduction from the same firm called Acme, and well worth a trial; it may be called a larger Chelsea Gem. One of its parents was the old Stratagem. In the West of England probably Exonian is more grown than any other for first crop; it is a first-rate variety, 3 feet to 4 feet high, and very early. I have for many years grown Bountiful for early use; it is not a Marrow, but one of the most prolific varieties I know, a round blue seeded variety. Harbinger, a newer introduction, that was one of the best in the trials at the Royal Horticultural Society's gardens in 1901, is a splendid type. It may be classed as a superior American Wonder, pods longer, broader, and more prolific, very dwarf (under 12 inches), and a splendid amateur's variety for restricted spaces. Sutton's Duchess of York is also a grand early Pea, later than some, a 3 feet variety. For quality Early Giant and May Queen may be termed the best. These have a decided Marrow flavour, and are of medium growth, 3 feet to 4 feet, and in warm borders are most valuable. Another point with the strong-growing Peas is that it is an easy matter to stop the points of the shoots to induce dwarfness and earliness. No note would be complete that omitted Ideal; it is not unlike May Queen in quality, but very early, and one of the best flavoured Peas of the early section; it gained an award of merit in 1901. It will be seen there is no lack of variety, and others of equal quality could be named if necessary. G. WYTHES.

(To be continued.)

## THE EDITOR'S TABLE.

WE invite our readers to send us anything of special beauty and interest for our table, as by this means many rare and interesting plants become more widely known. We hope, too, that a short cultural note will accompany the flower so as to make a notice of it more instructive to those who may wish to grow it. We welcome anything from the garden, whether fruit, tree, shrub, Orchid, or hardy flower, and they should be addressed to The Editor, 5, Southampton Street, Strand, London.

FLOWERS FROM KIDDERMINSTER.

Several delightful spring flowers come to us from Mr. Arthur Goodwin of The Elms, Kidderminster. One of the sweetest is *Iris reticulata* var. *Melusine*, which was referred to last week. The flower is as fragrant as that of *I. reticulata*, soft blue, with a broad line of rich yellow set amongst white on the broad fall. A little bunch of *Cyclamen Coum* reminds us of the cheery colouring and vigour of this species, which is far too little seen in English gardens. *Galanthus byzantinus* and *G. Elwesii* are two handsome Snowdrops. *G. Elwesii* has larger, more oval segments, a bolder flower altogether, but *byzantinus* has a gracefulness which *Elwesii* does not possess.

SOME WINTER FLOWERS.

I am sending a few sweet-smelling flowers for your table. I think I have sent you some of both before. The Winter Heliotrope and the Winter Sweet are now filling the garden with their rich fragrance, and I thought a few blooms would please you. I often think how very much poorer

those gardens are where these two interesting plants are not grown. They may be cultivated in any out of the way place where scarcely anything else will grow. I have a large bed of *Tussilago* fragrans growing near the stokey-hole, and the *Chimonanthus fragrans* covering the back wall in close proximity to it, and I find them both very valuable at this dull season of the year.—T. B. FIELD.

[We remember our correspondent sending these winter flowers before, but we cannot have too much of such fragrant things as the Winter Heliotrope and the Winter Sweet (*Chimonanthus*). The waxy yellowish colour of the *Chimonanthus*, its sweet scent, and freedom make this one of the most delightful shrubs that bloom in winter. There are many outdoor winter flowers, but we are thankful for such good things as these.]

## AN HOUR WITH THE HOLLYHOCK.

(Continued from page 411, Vol. LXIV.)

A FEW years since gardening was confined to the opulent, the man of leisure, or the curious. Now, few men of business are without their pet flowers—their Hollyhocks, Roses, and the like. Even our husbandmen, whose gardens are, as they should be, chiefly devoted to the useful, can yet find spare nooks in which to place the flowers they love. And whether they be the wild flowers of their native valley, gathered in their course to or from the scenes of their labour, or a few exotics, the gift of some kindly neighbour, they become alike tokens of industry and sweet memorials of home. Modern changes have made gardening comparatively inexpensive, and one of the greatest recommendations is its freedom from selfishness—its accessibility to all. Yes, indeed, the cultivation of flowers is one of the least selfish of human pleasures; it has a special tendency to subdue this dominant principle of the human breast. How few of the gardens of the wealthy in this land are altogether closed to the public, and the number of visitors to them testifies at once their sense of the boon conferred and their appreciation of the beautiful objects they contain. And while the tendency of these visits is to improve and refine the less wealthy who may thus enjoy what their means does not enable them to possess, they promote a kindly feeling, and help to bind together the various classes of the community.

The flowering season, then, is at length arrived, and with what pleasure do we hail the first flowers as they break upon the sight. With their expansion we feel rewarded for the year's toil. What symmetry of form marks our choicest productions! What variation, what brilliancy, and what delicacy of hue pervade the assembled mass! Well may we exclaim as we admire—

"Who can paint  
Like Nature? Can imagination boast  
Amid its gay creation hues like her's?  
Or can it mix them with that matchless skill,  
And lose them in each other, as appears  
In every bud that blows?"

The interest increases day by day; every visit, however oft-repeated, discloses some new candidate for admiration—"something to please and something to instruct"—till from the solitary flower blushing at the base of the spike the flower stalk rises a column of beauty. The spike, at the time of the expansion of the blossoms, is probably 5 feet or 6 feet high; and as we count the rows of embryo flowers which stud its length, and know that they will still expand, we wonder where and when our joys will end. The arrival of winter alone is likely to stay their unfolding, and that is too far in the distance to mar our present enjoyment.

It should be our aim to preserve the column as long as possible. If any flowers expand irregularly, of bad colour or form, they should be immediately cut out, when the space created by their removal will be filled up by the fuller expansion of the surrounding flowers.

There is now an additional demand on our activity if the flowers are required for exhibition. One of the most urgent of the requirements of our favourites is a shade to protect them from sun, rain, and wind. Where the plants are so disposed to admit of it a canvas awning is perhaps the best contrivance. Let it be so constructed that it may be drawn up and down at pleasure, and used only as a protection against rain and strong sunlight. But there are circumstances under which each plant may require a separate shade, and how shall we accomplish this? Four pieces of deal quartering, about an inch or an inch and a quarter square, may be nailed together in the form of a pyramid, and of a given height, according to the height of the variety. This placed over the plant, the lower ends are fixed firmly in the ground, and the part where the flowers are is covered with cheap calico dressed to stand the weather.\* The bottom or top of this shade being entirely open, it is particularly cool, and, being much narrower at the top than at the bottom, the flowers are well shielded from the sun and rain.

Now, for a time at least, we have little to do but to enjoy their beauty. If the weather be dry, frequent and copious waterings must be made; for the Hollyhock is a great consumer of moisture, and the water should be given in such quantity that it may sink into the soil to a considerable depth.

W. PAUL, F.L.S.

(To be continued.)

## ORCHIDS.

### DENDROBIUM GLOMERATUM.

**M**ESSRS. HUGH LOW & CO., Enfield, showed this comparatively rarely-seen *Dendrobium* at a Drill Hall meeting of the Royal Horticultural Society last autumn. The home of this species is the Malay Archipelago, whence it was introduced some ten years ago. It is allied to the interesting *D. secundum*. The plant is of strong growth, and the flowers are produced in bunches from the nodes of the stems, which are 2 feet or 3 feet high in well-grown plants. The individual flowers are about 1½ inches across, sepals and petals rosy purple, and the lip deep orange, the latter being continued into a funnel-shaped spur. Altogether this is an Orchid that is well deserving of extended culture. T.

\* The following glaze for calico is recommended by *The Gardeners' Chronicle*: "Three pints of old pale linseed oil, one ounce of sugar of lead, and four ounces of white resin. The sugar of lead must be ground with a small quantity of the oil, and added to the remainder, incorporated with the resin by means of a gentle heat. Lay it on the calico with a brush. One coat annually is sufficient."

### SEEDLING ORCHIDS AT MESSRS. W. BULL AND SONS.

#### ODONTOGLOSSUM CRISPUM.

On a recent visit to Messrs. W. Bull and Son's nurseries I found the work of hybridising and raising of seedlings was being most successfully carried on. I was shown some beautifully spotted varieties flowering for the first time. The markings in these were very regular, both on the sepals and petals. In one house were several plants carrying good seed-pods. These had all been fertilised from

just making a start, and others less advanced were still in the seed-pots. There is no doubt that in the future there will be less chance of getting new Orchids among those imported, but this will be fully made up for by our English-raised varieties, and there is a wide scope for those who can give their attention to hybridising and can afford to wait for the results. Judging from the prices I have seen paid at public auction during the past few months, it would not require many distinct varieties to amply repay for growing a good number of seedlings. A. H.

### THE WEEK'S WORK.

#### BRASSAVOLA DIGBYANA.

NEW roots are now being emitted from this plant, offering a favourable season to repot or resurface, as necessity demands, in a compost of fibrous peat two parts, chopped sphagnum two parts, and good leaf-soil one part, mixing the whole well together, and adding some coarse sand. These plants should be treated as regards back bulbs, as I advised in last week's calendar for *Lælia anceps*.

In the past we have undoubtedly been wrong in cultivating this species in teak baskets and shallow pans. Since we placed our plants in pots we have seen a decided improvement, so I most strongly recommend that pots should be used, filling them to quite half their depth with chopped rhizomes; pot rather lightly. A light position should be afforded them in the stove Orchid house, but I do not think they require much direct sunshine during the brightest part of the year. Until the season is more advanced they will not require much water.

#### ZYGOPETALUMS.

The winter-flowering ones, such as the good old species *Mackayii* — *Z. intermedium* — should be repotted as soon as the flowers have been removed. They prefer a good retentive compost, e.g., two-thirds fibrous loam and one-third leaf-soil, with a good sprinkling of small broken crocks and coarse sand. A thorough drainage of crocks should be given, filling the pots to one-third their depth, over which place some fibrous turf to prevent

the small particles of soil working down among the drainage. Do not repot unless the plant really needs it, but when repotting is done remove all useless back pseudo-bulbs, two being enough behind the one last made. The base of the young growths should be placed just a shade lower than the surface of the compost, and keep that a little below the rim of the pot. A light position in the coolest part of the intermediate house suits them well. Water must be applied with great discretion at first. It is most essential that the atmosphere of the house is kept sweet and buoyant by the free admission of fresh air, otherwise the foliage will become invested with black spots.

#### TREATMENT OF IMPORTED ORCHIDS.

Many Orchids are now being imported, among them being *Cattleya Mossie*, *Oncidiums* in variety, and *Odontoglossums*, and at first they are often given too much heat and light, which causes them to shrivel and lose leaves. The first thing to be done is to cleanse them thoroughly. I prefer potting them at once, but if time does not permit lay them on a stage in a cool, moist house and keep them well shaded. When potting remove all old pseudo-bulbs, with the exception of two or three behind each "lead" or growth, and pot in as small a receptacle as possible in the usual way. For some time they should be placed together so that they may be shaded from strong light in such a house as advised above, spraying them over on all favourable occasions. They will require practically no direct watering for some time. When root action begins give them more light and place

DENDROBIUM

GLOMERATUM.

(REDUCED.)

the finest varieties, and should result in some fine things at flowering time, which, of course, will be some years hence. The seedlings from the previous year's crosses were seen on the surface of the compost in the pots of growing plants, this being the most successful way of raising them. The seedlings were very tiny indeed, and required a practised eye to detect them among the growing sphagnum moss. More advanced seedlings were in small pots. It may be some years before these seedlings flower, and, though it may be an interesting study to watch their steady development, it must be rather tedious work until the first begin to flower.

#### CYPRIPEDIUMS.

Of this genus the seedlings were more numerous, some of the pots being thickly covered with the tiny plants in the first stage of development, and numerous pots and pans of plants in a more advanced stage were seen. None of these are chance seedlings, but all are the result of careful cross-fertilisation of the finest species and varieties yet known, and when they flower there should be some interesting work for the Orchid committee.

#### LÆLIO-CATTELYAS.

The seedlings of these were also seen in large numbers. Those one year old had only about three tiny leaves, and were in very small pots. Pans with about 100 seedlings pricked off in each were

them in the houses devoted to the respective sorts. Water very carefully until the plants are well rooted.

W. P. BOUND.  
Gatton Park Gardens, Reigate.

## NOTES FROM THE MARKETS.

### COVENT GARDEN MARKET.

**CINERARIAS.**—Several growers are now bringing in very good Cinerarias, and the bright colours are a welcome change. They are not quite so popular perhaps as they were a few years ago, and it is only the bright colours that sell well; these make from 8s. to 10s. per dozen.

**Azalea mollis.**—There are not yet many in the market, and they make good prices. At Messrs. Wills and Segar we saw some well-flowered plants a few days ago. There are a good many Indian Azaleas coming into market now, but some of them are not very well flowered; the best plants make good prices. Whites, chiefly Deutsche Perle, are most plentiful. Lily of the Valley in pots is very good just now, and some are sold at quite a moderate price.

**Heaths.**—We shall soon have a good supply of Erica wilmoreana. We saw some in one of the market nurseries a few days ago, but they were not flowering quite so well as they do some seasons, and we may expect to hear the same of other growers, for the continued wet during the autumn must have affected these.

**Cyclamen.**—A good many growers are now bringing in well-flowered plants, and some have to be sold at much lower prices, but one grower told me he could still command 18s. per dozen for best plants.

**Mignonette** in pots is already coming in, but it is not yet very good; we must have more sun before this can be well flowered.

**Poinsettias** are holding out much later than usual. On Saturday there were some to be seen with very good heads of bracts. Solanums are still to be seen, but there is little demand for them.

**Palms and Ferns** are plentiful, and there is better demand for them. Now that all the hardy foliage and Christmas green are cleared up we may expect better trade for pot plants.

Many growers have now finished with Chrysanthemums, but there are still some good blooms coming in. Callas are very plentiful and cheap. There are not so many Liliums now. Tulips and Daffodils are the most plentiful of all cut blooms. Roses continue to be scarce, but we may expect to see a large increase in the supply in the course of two or three weeks time. Good English Carnations also continue to be short. A few bright days will make a great difference in the supply of these. Primrose roots in flower are already to be seen.

## BOOKS.

**The Book of Town and Window Gardening.**\*—Many a town-dweller and owner of a suburban garden will find helpful suggestions in Mrs. Bardswell's book. The most interesting portion is perhaps that which concerns the beautifying of some of the ugliest spots in crowded London, the efforts of working folk and even of the very poor to have the joy of a few flowers or some growing green thing to brighten the little dismal space of yard or roof or window-box.

There are flowers, and, above all, Ferns, that defy the smoke and gloom of London, and the truth of the old saying "Where there's a will there's a way" is shown in the success that rewards the ingenuity and perseverance of many a working man who will have some flowers about him.

A happy example of what may be done on a roof is shown opposite page 30—"A Roof Garden." Nothing is much uglier than corrugated iron. Here this unsightly material is covered with a mass of flowering plants.

\* "The Book of Town and Window Gardening," by F. A. Bardswell. John Lane, London, 1903.

## SOCIETIES.

### SCOTTISH HORTICULTURAL ASSOCIATION.

THE February meeting of the Scottish Horticultural Association was held in Dowell's Rooms, George Street, Edinburgh, on the 2nd inst. Mr. J. W. M'Hattie, president, presided over a large attendance of the members. A number of new members were elected. There were several exhibits upon the table, among them being some lovely sprays of Clematis indivisa from Mr. William Smale, Blackford Park, Edinburgh. Mr. T. A. Scarlett exhibited Potatoes, selected samples of Northern Star. A tuber of Eldorado, which weighed 2½ oz., was said by Mr. Scarlett to be worth £25. The lecture for the evening was on the subject of "Planting of Ornamental Shrubs and Trees." It was contributed by Mr. James Whytock, gardener to the Duke of Buccleuch, Dalkeith Palace. Mr. Whytock has for many years made a special study of this subject, and his lecture was an excellent one, which would require a verbatim report to do it justice. He touched upon the value of the various classes of ornamental shrubs and trees, recommending a proportion of each, and laying special stress upon those which were valued for their foliage. The paper was a valuable contribution to the subject. The usual vote of thanks was heartily accorded to the lecturer, and the interesting discussion only served to support Mr. Whytock's views.

### DUNDEE HORTICULTURAL ASSOCIATION.

THERE was a good attendance at the monthly meeting of the Dundee Horticultural Association in the Technical Institute on the 2nd inst. Mr. James Reid presided. The paper for the evening was by Mr. Charles Blair, Preston House Gardens, Linlithgow, the subject being "Early Vegetables and How to Have Them." Mr. Blair has lectured on a somewhat similar subject before the Scottish Horticultural Association, and his Dundee paper will add to his reputation as a lecturer on the cultivation of vegetables. In the paper Mr. Blair confined himself almost entirely to the cultivation of early vegetables under the more natural conditions, and he pointed out various methods by which a supply of home-grown produce could be secured at a time when there were generally only imported vegetables at command. That the paper was a most practical one was the prevailing feeling of those who took part in the interesting discussion which followed, but there was some difference as to questions of detail expressed by some of the speakers. Mr. Blair was very heartily thanked for his valuable paper, and the chairman's services received a similar mark of appreciation.

### ABOYNE, N.B., HORTICULTURAL SOCIETY.

A MEETING of the above society was held a few days ago in the Public Hall, Mr. A. Grant presiding. Mr. Cowie was appointed secretary in place of Mr. Black. Mr. Robert M'Hardy and Mr. Robert Wilson were added to the professional committee in place of Mr. Ingram and Mr. Ironside, and Mr. D. Stewart and Mr. A. Hogg to the amateurs' committee. The prize schedules were also revised.

### ROYAL HORTICULTURAL SOCIETY.

#### SCIENTIFIC COMMITTEE.

PRESENT: Dr. M. T. Masters, F.R.S. (in the chair), Messrs. Gordon, Odell, Shea, Worsdell, Saunders, Michael, Bowles, Massee, Holmes, and Fraser, Dr. M. C. Cooke, Revs. W. Wilks and G. Henslow, hon. secretary.

**Codlin moth in May.**—Mr. Saunders made the following contribution to this subject discussed at the last meeting: "I cannot find that more than one brood has ever been noticed in England of the codlin moth, though two broods are common on the Continent and in America, and on the other side of the Atlantic three broods have been known. In this country the moth leaves the chrysalis in May, and lays her eggs very soon afterwards. The caterpillars are hatched in the course of a week or ten days, and remain in the Apple three weeks or a month. Being full fed, they leave the fruit to fall to the ground, and make their way to the nearest tree stem and crawl up it until they find a suitable place to pupate in. If they cannot find a tree a post or paling or even dead leaves will provide them with a shelter. The object in putting bands round the trees is to provide the caterpillars with hiding places, where they may be found and destroyed. They are not sticky, but made of folded canvas or sacking, or even hay or straw bands, and should be put on as soon as any 'wind-falls' are found."

**Maggots in Moss litter.**—Mrs. Horseley sent samples with enquiries. Mr. Saunders reports as follows: "The grubs found in the Moss litter manure were those of a fly belonging to the genus Bibio, but I cannot tell the name of the species, several of which are very common. Perhaps the one best known is the St. Mark's fly (Bibio Marci), so called from its generally appearing about St. Mark's Day (April 25). These flies are quite black, and are rather more than half an inch in length. Their bodies are rather thin, and the wings are not very transparent, and measuring about 1½ inches from tip to tip. They fly in a very clumsy manner, and may be found crawling over plants, &c., in great numbers for a day or two, and then they disappear altogether. The flies may be easily caught in a butterfly net. If poultry are kept I should spread the manure about and let them pick and scratch it over, for they will soon pick out the grubs. Mixing nitrate of soda with the manure might be tried, but I am not sure whether it would have much effect on the grubs, as I have not heard of any experiments having been made on them. They are undoubtedly injurious to the roots of plants at times."

**Coloured photographs of Orchid.**—Mr. Odell exhibited a coloured photograph of Cypripedium insigne Sanderae, executed by a new method. The yellow colour was very characteristic. It was received from Mr. A. S. Hickley, Kelso House, near Southampton.

**Liza discused.**—Mr. Shea showed leaves of I. crateroides as being the only species with the foliage discoloured. There

was no fungus present, the appearance being thought to be due to hereditary predisposition.

**Eucalyptus with nodules.**—Mr. Saunders showed small plants with nodules on the stem close to the ground. Nothing could be found inside. Mr. Massee observed that ants can cause similar ones on Roses, the formic acid acting as an irritant, and knots can be produced artificially.

### DRILL HALL MEETING.

#### ORCHID COMMITTEE.

Present: Harry J. Veitch, Esq. (chairman), Messrs. James O'Brien, de B. Crawshaw, James Douglas, E. Hill, J. G. Fowler, Jeremiah Colman, F. W. Ashton, H. T. Pitt, W. A. Binley, F. A. Rehder, R. A. G. Thwaites, H. J. Chapman, A. A. McBean, J. Wilson Potter, W. Bolton, J. Charlesworth, H. Ballantine, M. Gleeson, W. Boxall, W. H. Young, H. A. Tracy, W. H. White, F. Sander, H. Little, R. Brooman White, and Walter Cobb.

Messrs. Sander and Sons, St. Albans, had a magnificent display of Orchids, filling one side of a table. Dendrobiums and Phaius, together with Palms, made a delightful background, while Cypripediums, Cymbidiums, Phalaenopsis, Odontoglossums, Cattleyas, Lælio-Cattleya, &c. made an admirable display in front. The gold medal was awarded to Messrs. Sander for this group, a remarkably fine one. Among the Cattleyas and Lælio-Cattleyas were C. Trianae Purple King, C. Trianae delicata, L.-C. warnhamensis, L.-C. lucasiana var. hindeana, L.-C. blethleyensis, and L.-C. b. Illuminator. Cypripediums were numerous, and included C. Monarch, C. lamontianum, C. J. Bertels, C. aureum var. Excelior, C. Transvaal, C. Cyrus, C. Annie Measures, C. Sallieri aureum, and C. Brilliant (buchaniana × Calypso). The Dendrobiums were finely flowered, and there were some good Odontoglossums, such as O. nevadense, O. wilckeanum, O. w. chrysoxanthum, and O. crispum varieties. Among other Orchids in this group were Maxillaria luteo-alba, Cymbidium lowianum concolor, Miltonia bleana splendens, Phalaenopsis schilleriana, and others. Gold medal.

N. C. Cookson, Esq., Wylam-on-Tyne (gardener, Mr. H. J. Chapman), exhibited some very pretty Odontoglossums, many beautifully marked forms were included, and the plants were well flowered. Among them were O. crispum Brilliant, O. Adriane Oakwood var., O. Pescatorei albescens, O. crispum xanthodes. Cattleya choconensis alba and other choice Orchids were shown. Silver Flora medal.

Messrs. Charlesworth and Co., Heaton, Bradford, exhibited a group of Orchids, in which Lælio-Cattleya Charlesworthii was, as usual, conspicuously bright. It is a most valuable midwinter Orchid. Cattleya Enid (C. Mossie × C. gigas), a large flower with rosy purple sepals and petals, and rich purple lip; L.-C. Lilian, L.-C. Sallieri, C. gaskelliana, L.-C. gottoiana (L. tenebrosa × C. Warneri) and Cattleya Enid (C. Mossie × C. gigas) made a handsome display, and other good things were Celyogone sparsa, Dendrochilum glaucum, Brasso-Lælia Mrs. M. Gratrix, Odontoglossum Adriane Duchess of Cornwall, Cypripedium Lilian Greenwood, C. cardosianum (C. barbatum Warneri × C. leianum albertianum), C. Hitchinsiae, and C. villosum auriferum. Silver Flora medal.

Messrs. B. S. Williams and Son, Holloway, N., had a very bright group of Orchids, including some good Cypripediums, for instance, C. leianum superbum (well bloomed), C. politum, C. pitcherianum Williams var., C. harrisianum superbum, C. mearesianum, C. williamsianum, and others. Lycaste lasioglossa and L. Skinneri were well shown also. Silver Banksian medal.

In the group shown by Messrs. Hugh Low and Co., Bush Hill Park, Enfield, N., were some very good Phalaenopsis schilleriana, P. stuartiana, and P. amabilis, a splendid plant of Cattleya Trianae (carrying sixteen flowers of fine form), Dendrobium crassinode (full of flower), Barkeria elegans, a fine form of Cattleya Trianae, and C. T. alba. Other good Orchids were Cypripedium Thompsoni and C. Thompsoni inversum, Cymbidium affine, and Goodyera discolor. Silver Banksian medal.

Messrs. James Veitch and Sons, Limited, Chelsea, showed a small group of hybrid Orchids, viz., Cypripedium aureum virgiale, C. Gertrude superbum, C. Euryades excellens, and Zygopetalum leucocolum.

Mr. H. Tracy, Twickenham, showed Cypripedium Ethel × insigne punctatum Charlesworthii.

Flowers of Lycaste costata were shown by Mr. Henry Little, Twickenham.

M. Charles E. Vuylsteke, Loochristi, near Ghent, Belgium, exhibited Odontoglossum wilckeanum varieties and a very handsome hybrid Cattleya.

Cut racemes of Dendrobium speciosum were shown by S. Taylor, Esq., Marjory Hall, Reigate.

G. F. Moore, Esq., Chardward, Gloucestershire (gardener, Mr. Page), showed a group of Cypripediums in some lovely forms. There were C. aureum virgiale, C. Miss Amy Moore, C. nitens × Boxalli, C. Hera Euryades, C. Euryades Chardward var., C. Sallieri aureum, C. Sunrise, C. mooreanum, and others. Several obtained awards of merit, and are described elsewhere. Silver Banksian medal.

H. T. Pitt, Esq., Stamford Hill, showed Cypripedium pellianum, a handsome flower with greenish sepals, and petals heavily spotted with black.

Messrs. J. Cypher and Sons, Cheltenham, were given a silver Banksian medal for a group of Orchids in variety. Included were Cattleya Trianae, Lælio-Cattleya Hippolyta, Cypripedium lathamianum, C. villosum giganteum, C. vexillarium, Dendrobium Cybele, D. Domitii, D. schneiderianum, and others. Silver Banksian medal.

Baron Schröder, The Dell, Egham (gardener, Mr. Ballantine), sent flowers of Odontoglossum elegans, East Wood Park variety.

#### NEW ORCHIDS.

**Cypripedium Adippe.**—A large handsome flower, with the upper part of the dorsal sepal hending over, and keel-shaped; it is a rich crimson except for a green base, and has a white margin. Petals and lip are greenish brown. The parentage of this Cypripedium is unrecorded. From Captain Holford, C.I.E., Westonbirt, Tetbury (Orchid grower, Mr. Alexander) and Messrs. Charlesworth. Award of merit.

*Cypripedium aureum virginale*.—A very attractive flower. The dorsal sepal, recurving towards the base, is white, except for the light green base and a tinge of rosy crimson in the centre. The broad petals are light green marked with brown, and the lip is rather darker. From G. F. Moore, Esq., Chardwar, Gloucester (gardener, Mr. Page). Award of merit.

*Cypripedium W. H. Page*.—A charming little flower, the result of a cross between *C. niveum* and *C. Boxalli atratum*. Dorsal sepal and petals are heavily spotted with crimson upon a waxy white ground, and the long narrow lip is white suffused with palest green and with a few faint crimson dots. From G. F. Moore, Esq. Award of merit.

*Cypripedium Thompsoni*.—This is a bold flower, of handsome colouring, whose parents are *C. villosum aureum* and *Calypso*. The shining lip and petals are green and brown, and well formed, while the dorsal sepal, recurving towards the base, is white suffused with crimson, and green at the base. From G. F. Moore, Esq. Award of merit.

FLORAL COMMITTEE.

Present: W. Marshall, Esq. (chairman), Messrs. H. B. May, G. Nicholson, W. G. Baker, R. Dean, J. Green, E. Molyneux, R. Hooper Pearson, G. Reuthe, J. Jennings, C. R. Fielder, Charles Dixon, W. Bain, C. J. Salter, Charles Jefferies, H. J. Cutbush, J. A. Nix, R. W. Wallace, R. C. Notcutt, Charles E. Shea, W. P. Thomson, R. Wilson Ker, W. J. James, E. H. Jenkins, C. T. Drury, and Charles Blick.

Messrs. J. Hill and Son, Edmonton, set up a capital exhibit of Ferns, many of which were of good size. *Gleichenia rupestris*, *Davallia tenuifolia Veitchii*, *Osmunda palustris*, *Polypodium glaucum*, *Gleichenia dicarpa longipinnata*, *Woodwardia radicans cristata*, *Brainea insignis*, *Gymnogramme schizophylla gloriosa*, and *Gleichenia fiabellata* were among the best in this excellent group. A basket of *Saxifraga sarmentosa tricolor* was also shown. The variegated and green forms of *Ficus repens* gave a good margin to the whole. Silver-gilt Banksian medal.

Messrs. William Cutbush and Son, Highgate, contributed a very interesting lot of hardy things. Irises of the early bulbous section, *Sternbergia fischeriana*, *Saxifraga burseriana*, *Megasea Stracheyi*, *Daphne blagayana* (fragrant white flowers in trusses), *Leuten Rosens*, *Saxifraga Giesbackii*, Irises reticulata, and double Primroses were among the most interesting. *Prunus triloba pl.*, Lilacs, and other forced plants were also shown. Silver Banksian medal.

Messrs. Hogh Low and Co., Bush Hill Park, N., set up a fine lot of Cyclamens in many colours—pink, white, and reds, with salmon shades predominating. The white kinds were especially good, the flowers large and well formed.

Mr. G. Reuthe, hardy plant grower, Keston, Kent, had a small group, in which Irises, early Crocus, Snowdrops, *Shortia*, *Cyclamen Coum album*, *Colchicum libanoticum*, Iris histrioides major (very fine), and *Crocus suaveolens* (quite a charming pot) were especially observed.

Messrs. Cannell and Sons, Swanley, again sent *Coleus thyrsoides* in the cut state, showing the fine blue of its flowers.

Mr. Godfrey, Exmouth, again sent *Chrysanthemum Winter Queen*, the white Japanese, which we commented upon at the last meeting.

Hardy alpine and allied things were in strong force from Messrs. Ware, Limited, Felcham, and here we noted Blue Primroses, *Primula megaseae-folia*, *Cyclamen Atkisti*, *Lithospermum rosmarinifolium*, a lovely blue; *Saxifraga burseriana*, *Anemone blanda* in variety, *Adonis amurensis*, buttercup-like yellow; many *Crocus* species, and other interesting plants. *Scoliopus Bigelovii*, *Chamaelirium caibianum*, *Shortia uniflora*, and *Tapekea radicans* were among the rarest plants here set up.

Messrs. Mount, Canterbury, showed forced *Roses* such as *Liberty*, *Mrs. Sharman Crawford*, *Niphetos*, *Mrs. Grant*, *Caroline Testout*, *Mme. Gabriel Luizer*, &c., all in perfect condition. The fragrance of the flowers was most welcome at this early season, and attracted many admirers. Silver Banksian medal.

Messrs. Wallace and Co., Colchester, showed *Primula megaseae-folia*, of which there were some good forms. *Colchicum montanum*, pale lilac, with dark anthers; *Iris Danfordiae*, *Tellima grandiflora*, *Adonis amurensis*, Snowdrops, and several forms of *Iris stylata*.

Messrs. Sutton and Sons, Reading, set up a large group of *Primula The Duchess and Double Duchess*. It is the former kind that a year or more ago was granted the award of merit, and the more we see of it the more we are convinced of its good qualities. The combination of white, carmine centre, and yellow eye is very striking. Double Duchess is of the same character, but with double flowers. Brilliant King is the most wonderful colour in *Primulas* we have yet seen. It is a ruby-crimson with blackish centre and yellowish eye, a most striking variety. Giant White, Fern-leaved White, Terra-Cotta, and Giant Pink are all of exceptional merit.

Sutton's Blue Star *Primula* is perhaps the most decided break in the *P. stellata* group. Very distinct in colour, and good in form it is likely to be in demand. Silver-gilt Flora medal.

Hardy flowers from Messrs. Jackman, Woking, included *Clematis cirrhosa* and many Irises, such as *I. Heidreichi*, *Tauri*, *reticulata*, *Krelagei*, and *Danfordiae*, with Snowdrops and a beautiful soft pink single *Primrose* that is very charming.

From Messrs. Veitch and Sons, Limited, Chelsea, came a group of greenhouse plants, such as *Coleus thyrsoides*, *Eupatorium verale* (white), *Jacobinia coccinea*, and *Cheiranthus kewensis*, supported by tall Palms, &c. Silver Banksian medal.

A long table filled with *Primula sinensis* in variety came as a contribution from Messrs. Cannell and Sons, Swanley. Fairish of the Fair (white), Firefly, Miss Doris (white), and Kentish Queen (white) were among the important kinds shown. Silver Flora medal.

Mr. John Russell, Richmond, had a fine display of *Azalea Anthony Koster* (golden), with forced Lilacs, *Azalea indica*, *Hammamelis arborea*, *Daphne indica*, and such like things. Silver Flora medal.

Messrs. Barr and Sons, Ditton, put up an excellent exhibit, in which Snowdrops, Irises, *Narcissus minimus*, *Iris reticulata* (very fine), *Primula obconica*, *Saxifraga burseriana*, *Heliolebor lutescens*, *Fritillaria orantensis*, *Muscari azureum robustum*, *Crocus susianus*, *Narcissus cyclamineus*, *Iris stylata*, &c., were included. Silver Flora medal.

Hardy rock and alpine plants came from the Misses Hepatics, Mere, Cheshire, comprising Saxifrages, Primroses, Hepatics, Blue Primroses, gold-faced Polyanthus, &c.

A small exhibit of rock plants came also from Messrs. Cheal and Sons, Crawley, Hellebores, Aconites, Primroses, and rock shrubs contributing to the display.

Mr. W. Palmer, Andover Nurseries, Andover, set up a capital group of *Primula sinensis* of a semi-double character. The plants were well grown and freely flowered. Bronze Flora medal.

An exhibit of *Primula sinensis* in some charming varieties, though none received distinction, came from Mr. C. Burberry, Castle Gardens, Arundel.

Mr. H. T. Dixon, Woodside Nurseries, Polegate, showed some admirable plants of *Cyclamen persicum* of a pure white and finely grown.

AWARDS.

*Eupatorium verale*.—A pure white-flowering species of merit. The leaves are roughish and ovate acuminate. From Messrs. James Veitch and Sons, Limited, Chelsea. Award of merit.

*Tulipa kaufmanniana arva*.—A variety in which the golden character is strongly pronounced. It is a fine addition to early Tulips. From Messrs. Cutbush and Son, Highgate. Award of merit.

*Begonia Mrs. H. J. Dixon* is a pink-flowered sort, apparently with much of the *superflorens gigantea* in it. It is a freely-flowered plant and a good winter flower. It is said to be raised from *Schmidt alba* and *Goliath*, the former being the seed parent. From Mr. H. J. Dixon, Woodside Nursery, Polegate. Award of merit.

FRUIT AND VEGETABLE COMMITTEE.

Present: George Bunyard, Esq. (chairman), Messrs. W. Balderson, J. Cheal, W. Bates, George Woodward, S. Mortimer, Alex. Dean, W. Pupe, Horace J. Wright, W. Fyfe, James Gibson, Edwin Beckett, Henry Parr, G. Reynolds, F. Q. Lane, John Lyne, J. Jaques, Owen Thomas, James H. Veitch, George Wythes, A. Herrington, and A. H. Pearson.

The only exhibit before this committee was a dish of *Pear Passe Crassane*, from Mr. George Woodward, Baham Court Gardens, Maidstone. They were delicious. Cultural commendation.

ANNUAL GENERAL MEETING.

The annual general meeting of this society was held on Tuesday last in the Drill Hall, Westminster. Sir Trevor Lawrence, Bart., was in the chair, and was supported by members of the council. There was a large attendance, over 300 chairs being filled, and a number of persons were standing.

The secretary read the notice convening the meeting, the minutes of the last general meeting, a list of seventy-five ladies and gentlemen proposed (and subsequently elected) as Fellows, and the following:

"According to the provisions of the New Charter the following gentlemen retire from the council, but are eligible for re-election, viz.: Sir Trevor Lawrence, Bart., V.M.H., Mr. J. Gurney Fowler, and Mr. James Hudson, V.M.H. The following gentlemen have been duly nominated to fill the vacancies, viz.: Sir Trevor Lawrence, Bart., Mr. J. Gurney Fowler, and Mr. James Hudson, V.M.H. The following have been nominated for election as vice-presidents, viz.: The Right Hon. Joseph Chamberlain, M.P., the Right Hon. the Earl of Dowie, the Right Hon. Lord Rothschild, Sir Frederick Wigao, Bart., and Sir John D. T. Llewellyn, Bart. The following have been nominated for election as officers, viz.: Sir Trevor Lawrence, Bart., V.M.H. (president), J. Gurney Fowler, Esq. (treasurer), Rev. W. Wilks, M.A. (secretary), and Alfred C. Harper, Esq. (auditor)."

Sir Trevor Lawrence, in moving the adoption of the report, said there was little new for him to add. This year would mark a great epoch in the society's history. It was established in 1804 at Hatchard's in Piccadilly, in a room at the back of the bookseller's premises that still exist. All who were interested in horticulture must view the position of the society with great satisfaction. At no period has it had so large a surplus income as last year, when it was £3,641. As an indication of the great changes which have taken place, Sir Trevor mentioned that in January of this year the total amount received in subscriptions was £5,757, more than the total amount received during the whole of 1900, only four years ago. This shows the rapid growth of the society, and indicates the interest that is now taken in gardening by a large number of people. The success of the society Sir Trevor thought to be due to the fact that it has persistently stuck to the prosecution of horticulture, and he thought that so long as this policy was continued the society would thrive. With reference to the matter of raising the annual subscription, Sir Trevor said the council had fully considered the matter, but they would leave it entirely in the hands of the Fellows. Doubtless they would be told by many that it was wiser to leave well alone, but Sir Trevor pointed out that the society's position is very different now to what it was some years ago, when the subscription was made £1 1s. There was no Temple show, no Holland House show, practically no journal, and no advice given to Fellows. Some had objected to the pecuniary value of the £1 1s. subscriptions as published in the Royal Horticultural Society's journal. It ought not to have been put quite like that; it should have read that every Fellow for his £1 1s. subscription *can* get returns to the amount given. "Some seemed to think," said Sir Trevor, "that there should be an entrance fee of one guinea, instead of raising the subscription," and this remark was greeted with applause.

Mr. Alexander Dean seconded the adoption of the report. He thought the council had done him the honor of asking him to second this resolution in order to show their appreciation of their committees; he was one of the oldest mem-

bers of the oldest committee. They must not forget that the new hall and garden would carry with them great responsibilities. Mr. Dean said there was a possible danger of the society being flooded with people who were not really interested in gardening; he thought they should endeavour to get new Fellows who are true horticulturists. Mr. Dean suggested that members of the trade should be exempt from any additional subscription, as well as *bona fide* gardeners. He was sorry to see no mention of any exhibition of vegetables in the arrangements for 1904, but trusted the council would see to it that they were not neglected.

Mr. H. J. Elwes suggested that the Royal Horticultural Society should do as some other societies do, e.g., the Zoological Society, and make the Fellows pay extra for the Journal. As it has increased in value so the expense of production has increased also. Mr. Elwes also asked if the council had considered the propriety of taking part of the balance of £17,500, accumulated funds to wipe off the deficit of some £16,000 still needed to complete the new hall. The subscriptions for this seemed to have been hanging fire somewhat last year. Mr. Elwes said that some considered the Wisley garden to be a white elephant, but he was not of that mind; there was, however, much to be done there that would entail considerable expense.

Sir Trevor Lawrence said he would leave it to the treasurer to reply upon the financial aspect of the question. With reference to the Journal, Sir Trevor said that Mr. Wilks told them, and the council fully believed it to be the case, that many joined the society simply to obtain the Journal, therefore it would be inadvisable to charge extra for it. They would, however, be glad to know if any Fellows did not wish to have the Journal.

Mr. Gurney Fowler (treasurer) said that Mr. Elwes had somewhat exaggerated the deficit necessary to complete the new Hall. The money promised and received amounted to £25,000, and the total expenditure would not be more than £40,000. They had received in donations £22,561, and interest on money temporarily invested £451, which, together with promised subscriptions of £2,113, amounted to £25,125. Of this £12,124 had been spent, leaving a balance in hand for present liabilities, with the amount of promised subscriptions, of £13,001. The contracts for the hall amounted to £34,780; they had already paid £10,379, leaving a balance to pay of £24,401; they had at present £13,001 to pay it with, leaving a deficit of £11,400. Mr. Fowler said that the furniture ought not to be considered as part of the cost of the building itself. The actual liquid assets of the society were about £20,000. It was proposed to lodge with the bank some of their investments for a temporary loan until it was seen how the subscriptions came in. Over £11,500 (unpromised) had been subscribed in January. They had great hopes that all the money would yet be subscribed by Fellows. If it became necessary they proposed to effect a mortgage through an insurance office (which had already offered to negotiate on favourable terms), which would be met out of the annual surplus. At a favorable opportunity they would probably sell some investments either to pay off the loan or redeem the mortgage, as the case might be. As the surplus income last year was £3,641, and they had already had 250 new members this year, they thought it could be depended upon.

Sir Trevor Lawrence said that their solicitors advised them that the Chiswick lease would bring £5,000, which would go towards the expenses of the Wisley garden. On behalf of the society he thanked the committees, who so ungrudgingly gave their services throughout the year; the secretary, whose work was invaluable; and the staff, who, both at Chiswick—under the superintendence of Mr. Wright—and in the office, have worked hard. They hoped in the future to have an assistant secretary; the work had increased so much that it was necessary to have more help. In consideration of the extra work thrown upon the office staff the council had granted an honorarium to them.

The adoption of the report was carried *unm. con.* Mr. Gurney Fowler proposed that Fellows be elected at an annual subscription of two guineas and be entitled to certain specified privileges, or at an annual subscription of four guineas and be entitled also to certain increased privileges. Mr. Fowler explained that this resolution did not affect present subscribers. The council wished to put this proposition and also an amendment in order to find out the wishes of the meeting. One reason of the proposed increased subscription was to raise the income of the society, on account of the new Hall. As the Fellowship increased so the receipts at the shows would fall, and the increase of Fellows meant more clerical work. It was felt that those joining now should pay more than those who had helped to build up the success of the society.

Mr. A. H. Pearson seconded this proposition. Mr. Harry J. Veitch proposed the amendment, which was to the effect that, except in the cases of a *bona fide* gardener, Fellows residing abroad, or paying a two or four guinea subscription, new members should pay an entrance fee of one guinea in addition to their subscription. Surgeon-Major Ince seconded the amendment, which he thought outlined an excellent and reasonable plan. No society gave such a Journal as the Royal Horticultural Society, and Major Ince compared it with that issued only once a year by the Royal Agricultural Society.

Mr. Elwes asked if the entrance fee would be treated as capital or income, but Sir Trevor Lawrence said that had not yet been considered. The amendment was carried by a large majority. Sir J. D. T. Llewellyn proposed a vote of thanks to Sir Trevor Lawrence for presiding, and this terminated the proceedings.

THE HORTICULTURAL CLUB.

The annual meeting of the members of this club was held on Tuesday, the 9th inst., at the Hotel Windsor, and was followed by the annual dinner, under the presidency of Sir John D. T. Llewellyn, Bart., at which about eighty members and guests, including on this occasion a liberal sprinkling of ladies, were present. At the meeting a very

satisfactory report of the progress of the club was read by the chairman, embracing not merely proofs of the increase of membership, but also abstracts of the various papers read during the year by some of the highest authorities in the horticultural world, attesting not only the social value of the club but its practical value as a factor of instruction and progress. The membership is now about 140, as compared with about half that at a number of years back, and it is hoped that in view of the accommodation afforded to those joining it, by the possession of comfortable quarters always available at the Hotel Windsor, its value as the recognised social centre of the Royal Horticultural Society will be still further utilised by the ever-increasing number of its fellows. The dinner, which was capitally arranged by the hon. secretary, Mr. E. T. Cook, was enlivened by the presence of the Georgian Singers, under the direction of Mr. Harry J. Stubbs, and their repertoire included a number of most charming songs, rendered in an equally charming way, both in the shape of quartettes and solos, jovial and serious. Mr. C. T. Drury, V.M.H., gave a humorous reading of his own entitled "Modern Chivalry," which was extremely well received, and in every way the meeting was pronounced to be one of the greatest social successes of the club.

After the usual patriotic toasts, Mr. George Gordon, V.M.H., in a felicitous speech, proposed the toast of the Royal Horticultural Society, depicting in graphic terms its vicissitudes in the past and its triumphal progress of recent years, as attested at the annual meeting held that day at the Drill Hall, and the credit was given which was certainly due to the Horticultural Club, that at the darkest period in the history of the society it was within the walls of that club that a scheme of regeneration was formulated and started, with the brilliant results in question. Mr. A. H. Pearson responded in an equally happy vein. The toast of the club itself, proposed by the president, Sir John D. T. Llewellyn, Bart., was naturally both well proposed and well received, Mr. George Monro responding in a humorously humble way as an outsider, which could hardly fail to tickle the fancy of all present, who recognised his value as a member and his general position in the horticultural world. Mr. Harry J. Veitch proposed the health of the president in his genial way, and the president, responding took the opportunity of reverting to Mr. E. T. Cook's invaluable services as hon. secretary, and proposing a special toast in his behalf, which was cordially received with the usual honours. A hearty vote of thanks was finally accorded to Mr. Harry J. Veitch and Mr. George Monro for the lavish provision of the former of floral table decorations and by the latter of a generous supply of fruit, embracing Peaches, Nectarines, and Plums from the Cape, which were of considerable interest as regards their novelty as well as merely gastronomically.

#### UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.

The usual monthly committee meeting of this society was held at the Caledonian Hotel, Adelphi Terrace, Strand, on Monday, the 8th inst. Mr. Charles H. Curtis presided. Fourteen new members were elected, making thirty-one in the two meetings this year. The annual general meeting will be held at the above hotel on Monday, March 14, at 8 p.m.

#### ROYAL HORTICULTURAL SOCIETY OF SOUTHAMPTON.

The annual general meeting of members of the Royal Horticultural Society of Southampton was held recently at the Municipal Offices. The forty-second annual report presented by the council is, with one exception, a most encouraging one. For the first time for many years a statement of accounts is presented in which the liabilities are nil, whilst the assets show a cash balance of over £90, as against £39 shown in the last report. This favourable result is mainly due to the two extra events held during the season, viz., the exhibition held in conjunction with the Royal Counties Agricultural Society's Show, and the garden fête held in the president's beautiful grounds. With regard to the first-named, this society is indebted to the council of the Royal Counties Agricultural Society in sanctioning the liberal arrangement made on that occasion, and it is very gratifying to note that in their report they give the horticultural exhibition credit for a large share in securing the great success that attended their Southampton show. The council gratefully acknowledge their indebtedness to Sir Samuel Montagu, Bart., for his great kindness in once more placing his grounds at South Stoneham House at the disposal of the council for a garden fête; his generosity in also allowing the salmon pool to be drawn for the benefit of the society's funds was greatly appreciated, and materially added to the success of the fête. The profits on this and previous garden fêtes have enabled the council to redeem, from time to time, the £5 bonds, and the whole of that liability has now been paid off. With a view of forming an adequate reserve fund, £25 has been added to the deposit account, and until this fund reaches at least £100 the council do not consider it expedient to sanction any material increase in the prize lists. The council regret to have to record a reduction of over £6 in the amount from annual subscriptions, and they earnestly appeal to the members and the public for assistance in the endeavours to improve the income from this source, as the prosperity of the society so much depends upon a good subscription list being maintained.

It may be added that the entries for the summer show, to be held in the Pier Pavilion on July 6 and 7, will close on June 30. There are fifty-one classes in the schedule. The autumn show will be held in the Skating Rink on November 2 and 3, and the entries for this show close on October 27. There are fifty-seven classes in the schedule, and the Queen Victoria Challenge Trophy, value £40, for Chrysanthemum blooms, is competed for at this show. The present holder is the Dowager Lady Ashburton.

The chairman, in moving the adoption of the report, referred to several of the items in it. He thought the

members must be very pleased to know that once again the society was out of debt, and it would be the effort of the council, if the public would only support them to keep out of debt; but they did wish for a larger share of public support, and for an increase in subscriptions. The paragraph which recorded a decrease of £6 in the subscriptions was a regrettable one. The secretary told him that the subscriptions were about the same now as when the population of the town was one-half what it was at present. Referring to the sources of income the society had had during the year, the chairman expressed obligations to the Royal Counties Agricultural Society for having allowed this society to hold an exhibition on the show grounds. He thought that that was the place to refer especially to the efforts of Mr. Toogood in securing that concession. Mr. Toogood, who was a member not only of the council of this society but also of the council of the Royal Counties Society, worked most energetically in the matter. The society must also not forget their president, Sir Samuel Montagu, who during the year was good enough to give the society the opportunity of holding in his grounds another fête, which materially helped to swell the society's funds.

#### NATIONAL CHRYSANTHEMUM SOCIETY.

On Monday evening last the newly-constituted executive committee of the above society held a very busy meeting at the usual rendezvous of the society, Carl's Restaurant, Strand. Mr. Thomas Bevan presided, and was supported by a fairly good attendance of members. Minutes, correspondence, and submitting the rough financial statement up to date occupied the attention of members for some little time at the outset. The treasurer explained that out of the amount due to the society at the date of the auditing of the balance sheet he had since received upwards of £70, and that the balance in hand actually amounted to £117 odd. The reserve fund now amounted to £115, and a deposit note for the same was produced. It was resolved that the secretary's salary for the year should be, as before, £100. The business relations with the Crystal Palace Company were then gone into, and the arrangements, both as to accommodation and pecuniary support for the forthcoming shows, highly appreciated. A motion was then made that the secretary be duly authorised to sign the contract between the Crystal Palace Company and the National Chrysanthemum Society. Arrangements as to a supply of tickets for members, exhibitors, and authorised Press representatives have also been placed on a satisfactory footing.

One-third of the floral committee retiring by rotation, an election was necessary. The following gentlemen were elected: Messrs. W. Howe, J. W. Moorman, D. B. Crane, Ingamells, Simmonds, and Kendal. The report of the schedule sub-committee was then submitted—this occupying much time, the discussion being very full on all points. About £50 more cash will be added to the prize list than was offered last year. Special prizes will be offered by the Ichthemic Guano Company, the president (Mr. C. E. Shea), Mr. W. Seward, and others.

Judges were next appointed. They are as follows, with suitable reserves in case of any falling out:—October Show: Mr. Henry Perkins and Mr. G. Langdon. November Show: Japanese blooms, Messrs. Carpenter, W. Meredith, J. Attman, J. W. McHattie; incurred blooms, Messrs. G. Lane and G. Woodgate; decorative and groups, Messrs. Beckett and C. Jordan; fruit and vegetables, Messrs. S. Cole and S. Mortimer; December show: Messrs. W. Mease and W. G. Drower.

Vacancies on the classification schedule and finance committees were filled, and a special sub-committee to undertake the arrangements in connexion with the exhibition of market varieties in December was appointed.

It was resolved that six of the society's small silver medals be presented, as on a former occasion, to affiliated societies, the presentation being made by ballot. New members were elected, and the Penarth Chrysanthemum Society was admitted in affiliation. The business was brought to a close by a proposition being made on behalf of Mr. Norman Davis that the society should create a department of Chrysanthemum nomenclature registration, in something after the same style as that adopted by the American society. The object of this will be to prevent the same name being given to different varieties, and also the recording of the raisers' names and dates of introduction of novelties. Mr. Harman Payne was nominated registrar for the present.

#### CARDIFF CHRYSANTHEMUM SOCIETY.

The seventeenth annual meeting of members of the above society was held on Friday evening, the 5th inst., at the Grand Hotel, Westgate Street, Cardiff. Mr. J. Julian occupied the chair, and the interest evinced in the society was shown by the fact that the attendance was much more numerous than usual. The annual report was submitted by the chairman. It stated the year 1902 ended in a loss of £18 1s. 3d., contingent on the outstanding subscriptions being recovered. Unfortunately, £4 9s. 3d. was irrecoverable, and this left a total deficit of £22 10s. 3d. at the beginning of the year 1903. The whole of that had been paid off, and the society would start the next year clear. The total subscriptions for last year amounted to £124—about £8 more than the year before. The door receipts were most encouraging, and amounted to £138 5s. 11d., being the highest since the year 1899, which was considered a record year, £129 9s. 3d. being taken at the doors. Altogether this was the best account presented for many years. The late show was admitted to have been one of the best both in respect of competitive and trade exhibits. The date of the next show has been fixed for November 2 and 3. Councillor Curtis was unanimously re-elected president of the society. All the vice-presidents were re-elected. Mr. John Julian, who vacated the chair, was unanimously elected as a vice-president, as a recognition and appreciation of his services to the society, especially for the past two years, during this time as chairman, he being mainly instrumental in bringing the society up to the high standard of excellence and

efficiency to which it has now attained. Mr. J. Grimes was elected chairman of committee; Mr. F. G. Treseder, vice-chairman; Mr. H. Gillet, secretary; Mr. H. B. Crouch, treasurer; and Messrs. Booth and Medhurst, auditors. Reference was made by the chairman and others to the cordiality with which the officers had worked, and much satisfaction was expressed that the prospects of the society were so promising.—H. R. F.

#### GARDENING APPOINTMENTS.

MR. QUINTON, for some years foreman under Mr. Reynolds at Gunnersbury Park, has been appointed head gardener to P. Jackson, Esq., Latchmere, Ham Common, Surrey. He entered on his new duties on the 6th inst.

MR. E. HENDERSON, for three years foreman in the gardens at Criche, Wimborne, has been appointed gardener to Lieutenant-Colonel W. H. Poe, C.B., Heywood Abbey, Leix, Queen's County, Ireland. He commenced his duties on the 6th inst.

MR. T. W. TURNER, for a number of years general foreman at the Royal Horticultural Society's gardens, Chiswick, has been appointed superintendent of grounds at the Royal Hospital, Chelsea.

#### OBITUARY.

#### SIR DAVID CARRICK BUCHANAN, K.C.B.

THE late Sir David Carrick Buchanan, K.C.B., of Drumpellier, who died at the Mansion House, Coatbridge, on the 9th inst., was one of the many gentlemen who find pleasure in country life, and whose gardens are among their greatest enjoyments. Sir David's garden at Drumpellier is a very beautiful one, and at Corsewall, Wigtonshire, a property to which he succeeded some years ago on the death of the late Mr. Carrick Moore, he had a very fine collection of shrubs. It will be remembered that a photograph of Hydrangeas at Corsewall appeared not long ago in THE GARDEN. Sir David, who was in his seventy-ninth year, was held in the highest respect by everyone, and his munificent gifts of various kinds to the inhabitants of Coatbridge caused him to be greatly esteemed there. Among other gifts, in 1866 he presented the West End Park to the people of Coatbridge.

#### ANSWERS TO CORRESPONDENTS.

**Names of plants.**—M. A. H.—*Billbergia* sp., but specimen not complete enough to identify the species.—J. S. H.—The large rosy purple flower is *Ruellia macraurtha*; the pale yellow one, *Justicia caticotricha*.

**Semele androgyna** (BROOM).—This used to be included in the genus *Ruscus*. It is a vigorous growing climber that needs a greenhouse. The cladodes are arranged on the minor branches in such a way as to suggest long, hard, leathery, pinnate leaves of a deep green colour. It is a native of the Canary Islands, from whence it was introduced in 1713. This *Semele* is a valuable climbing plant for very large structures, as may be seen at the Crystal Palace and in the temperate house at Kew. It cannot be readily obtained from nurseries, though occasionally it may be met with, generally as seedling plants.

**Garrya elliptica not flowering** (H.).—Your Garryas ought to flower in the positions you describe. Perhaps you have got the female form, and, if that is the case, you will not get catkins of flowers as you would with the male form, the flowers of the female being very inconspicuous. If the plants are females it would be advisable to unroot one and replace it with a male. Cuttings of the *Euphorbia* you mention should be taken in spring either of the one year old wood with dormant buds, or young, soft shoots 4 inches long with a slight heel of old wood. In either case, very sandy soil must be given, and a close and warm propagating case must be provided.

**Sweet Peas—a correction.**—In Mr. Sydenham's article on this in third column, line 8, for Gorgeux read George Gordon, and the same in the next line. On page 95 for Countess Jewell, read Crown Jewel.

#### CATALOGUES RECEIVED.

*Tuberous Begonias, Lilies, &c.*—Messrs. T. S. Ware, Limited, Feltham, Middlesex.

*Chrysanthemums.*—Messrs. W. Wells and Co., Earlswood Nurseries, Redhill, Surrey (together with life-size illustrations of novelties for 1904); M.M. Vilmorin-Andrieux et Cie., 4, Quai de la Mégisserie, Paris.

*New Chrysanthemums, Seeds, and Plants.*—Mr. H. J. Jones, Ryecroft Nursery, 11ther Green, Lewisham.

*Florist's Flowers and Hardy Plants.*—Mr. John Forbes, Hawick, N.B.

*Lath Roller Greenhouse Blinds, &c.*—Messrs. W. Walters and Co., 16, Water Lane, Great Tower Street, E.C.

\* \* \* The Yearly Subscription to THE GARDEN is: Inland, 15s.; Foreign, 17s. 6d.

# THE GARDEN

No. 1683.—VOL. LXV.]

[FEBRUARY 20, 1904.]

## SOUTH AFRICAN PEACHES.

THE arrival, in perfect condition, of a box of South African Peaches is still enough of a novelty to make it worthy of a note. Amidst the conflict of opinion on the subject of imported Asiatic labour and the temporary depression of mining operations in South Africa, it is cheering to know that in certain localities, notably in Cape Colony, the fruit-growing industry is steadily making its way. On the fruit farms where these Peaches were grown both Kaffir and Coolie labour is employed, under English supervision. The season has been unusually hot and forcing, and fruit of all kinds has ripened so early as to make the work of in-gathering more than ordinarily a matter of rush and toil. From 6 a.m. to 7.30 p.m.—a long day in burning heat—all hands have been hard at work in the orchards; but, judging by the Peaches just received, the present summer has favoured the development of the crop more than last season, for they are altogether finer and more highly finished than some which arrived last February. As to flavour, they have a good deal of the fine aroma of the Nectarine, which lends some support to the view that this particular kind may be of hybrid origin. Those who can enjoy the luxury of having Peaches and Nectarines on their tables in February need not grudge their cost. A luxury it is, but by indulging it we may not only "think imperially," but in one small way act as well, for we stretch out a helping hand towards the building up of thriving settlements of our own country-folk on the far-distant African veldt.

One may well ask how it is possible for fruit so perishable to travel 7,000 miles over land and sea, and yet arrive in good condition. To begin with, of course, Peaches, Nectarines, and Plums are gathered before they are fully ripe, and with the utmost care to avoid bruising. The boxes in which they are packed are 3 inches to 4 inches deep and large enough to contain from two to three dozen fruits in a single layer. These boxes are strong, but are not tightly fitted together, as there is sufficient room for some circulation of air between the interstices of the boards. A strip of wood below each end also allows a current of air to pass between each box when the final stacking takes place for the voyage. Each fruit is carefully wrapped in soft tissue paper and

tightly imbedded in fine wood shavings so that no movement can take place. But even so, with the utmost care in handling and with the help of cold storage, it is one of the marvels of this marvellous age that such a feat should be possible.

## MY SEA-COAST GARDEN IN WINTER.

"Earth slumbers, and her dreams—who knows  
But they may sometimes be like ours?  
Lyrics of spring in winter's prose  
That sing of birds and leaves and flowers."

WINTER, and how short the hours of daylight; how much too short for all we have to do in them. Already the round red sun is dipping down behind the grey church tower, lighting it up with fires of purple and crimson. The too brief day will die in splendour.

And the old garden on the bare sea cliff, with the little lichen-covered copse that guards it, how does that look on this quiet winter's day? So pleasant, so restful as it lies in the reflected glory of the sunset, that it is still the place we love the best, and in which the happiest hours are spent.

Most of the hardest work is over now—the tidying up, the mending of the neglected lawn, the clearing of the copse from rubbish, the thousand things that always must be done in a garden that has too long lain uncared for. More than one spring and summer will it take to coax this unkempt wilderness into order. Digging borders that have been left untilled for many years, and are crammed with odds and ends and stumps and roots of things long dead, is not at all the same as turning over new ground or ground that has been treated fairly every season. "Wholesome neglect," however, has shown its bright side in the copse, for there the sweetest things that grow have long run riot. "Nothing that has a bulb to it will live in that garden," said many friends who thought they knew; "rats and rabbits will make a meal off every one." Even the earliest spring months proved them wrong. Scattered Crocuses and Snowdrops were the first to greet us, and after them whole drifts and sheets of Bluebells, sprinkling the grass beneath the budding trees with sky colour—"God's own blue"—and later on whole families of Poet's Narcissus, starry and scented, and spread about with the grace that comes of freedom.

But now on this quiet winter's day, so enjoyable after weeks of windy weather, these flowers of spring, with all the other garden folk, are sound asleep and dreaming, as they should be. A Primrose or two, prematurely wakeful, shall go unnoticed, but one or two sweet-faced, leaf-hidden Violets must be forgiven for peeping out. Stray Violets are always irresistible, and the tiniest bunch, if brought indoors, is more full of fragrance than

half a dozen sachets of Violet scent from Bond Street

Flowers may sleep, but we are wide awake digging, as usual, planting and replanting, a safe and easy thing to do when all the garden children are deeply wrapped in slumber. The kind soil of this north-east sea-coast garden (porous, but not poor), its lingering sunshine, and protracted autumn make it a difficult matter to get the summer borders clear. Marguerites will go on blooming well into December, and sweet white Alyssum positively refuses to be taken out and made a bonfire of. It still smells sweet and keeps its colour. How it happens that so many plants live on through winters here that must certainly have died down in a Surrey garden is always a surprise.

October comes and takes us unawares. We are not yet ready for the smart new-comers, who arrive in well-packed boxes—sleeping beauties wrapped up like dolls in soft white paper, and neatly-labelled, curious chrysalises whose butterflies are of the kind that grow on stems. These fine folk are all kept waiting; but at last they settle down, and we are free to think of other things—Sea Hollies, for instance, and Sea Lavenders, that might do well outside upon the cliff; but we will try them in the garden first. Growing sea plants will be a new experience. The roots of some of them alone are quite delightful, so tough and strong, giving promise of the sturdy flowers that by and by will follow. Roots are so full of character and so interesting. Once we begin to notice the under-world of fibres, tubers, and "growing points," there is no end to it. It is just as fascinating as the sunlit world of hough and leaf and colour.

In this old garden, where so many fair things have been naturalised, it behoves us to walk warily. We must neither crowd the canvas nor strike a jarring note; its simple charm must not be spoiled. What things we do put in must be chosen very carefully; we must have exactly what is right—no make-shifts—and the experience of one season has taught us what the garden likes and wants, a much more weighty matter than the mere gratifying of our own tastes. Not many Roses could be happy here—we are too wind-swept and sheltered corners are too few—but we can have a sunny bed of Monthly China Roses close to the house, along with Rosemary bushes and Pansies and Carnations and Mignonette. The soil is exactly suitable for Pinks, and a whole cliff's depth of sandy loam, fertile and clean, calls out for every plant that owns a bulb or anything like it. This is our cue. In go the Lilies, white and orange; they shall be laid among the sleepy Ferns in a spot where sheltered sunbeams will look after them. Blue and white and yellow and velvety Iris shall find space too, English and Spanish, with other treasures.

How the old gardener, who has known the place so long, and been its only guardian for many empty years, enjoys the fatted calf of

better times. It is pretty to see him at his work. Unpacking and planting something new is such a treat. How carefully he lifts the clumps with kind brown hands, and sorts them out and lays them on his barrow, while "onlooker" is carrying his spade. Such eloquence about that spade! Its wood feels warm and worn and polished, and its blade is thin and sharp from constant use; it can do anything, from rough work to the finest. How deftly its owner thrusts it through the mould—a dexterous twist, and lo! a hole of any shape or size he wants appears like magic. Each new arrival is taken up and looked at, then gently laid in its appointed place.

"Like pious children, one by one,  
He sets them head by head,  
And draws the clothes when all is done  
Closely about each bed,  
And leaves his children to sleep on  
In the one quiet bed."

There has been plenty to do, too, among the creepers and climbers on the old house walls. Such a tangle as there was all summer-time of Jasmine, Honeysuckle, Virginia Creepers, Dutchman's Pipe, and one or two old-fashioned Roses. Now we can see which is which, and bring them into order. How the dry stems rattled in the wind! They have been knocking against the window panes like castanets. It seems so strange now to recollect the honey-scented draughts of summertime that blew in through the open windows. Anyhow, an old garden, with all its faults, is better than a new one, and if the sea winds are too rough with it at times the fine days make it up. Nowhere are colours more brilliant than in a seaside garden. Perhaps it is the saltness of the air that makes them vivid, as sprinkled salt improves the colours of a carpet.

Even the banks put up for shelter, not for ornament, must not be grumbled at. In spring they are so full of yellow Primroses, blue Speedwells, and spotted Orchids; and as for the kitchen garden, we can humour that by growing dwarf things that do not mind the wind.

We promise ourselves much amusement in the summer, when old and new inhabitants wake up and meet. Bowing and nodding acquaintances will soon strike up under the breezy influences of sea winds blowing from the waves. Amongst other things we will have a Poppy garden, fringed and fragile, and Giant Poppies can all have ample room between the meadows and the cliff. The one thing we ought never to forget here (there is danger of it) is Miss Jekyll's maxim, "Where things are well, let well alone."

The evening of this winter's day was dignified by a new moon. Very yellow looked its delicate thin curve against the blueness of the darkening sky, and just one star of hope shone out beside it. Could we have done better than breathe a new moon wish that all the garden's pretty dreams and fancies might come true?

F. A. B.

## THE EDITOR'S TABLE.

WE invite our readers to send us anything of special beauty and interest for our table, as by this means many rare and interesting plants become more widely known. We hope, too, that a short cultural note will accompany the flower so as to make a notice of it more instructive to those who may wish to grow it. We welcome anything from the garden, whether fruit, tree, shrub, Orchid, or hardy flower, and they should be addressed to The Editor, 5, Southampton Street, Strand, London.

### HELLEBORES FROM IRELAND.

Mr. Greenwood Pim sends from Monkstown, County Dublin, a dainty selection of the Lenten Roses. The colours are very beautiful, some quite self, and others with dark spots on an almost white ground. One named E. Muriel Pim is a warm chocolate-red, and of good shape. Mr. Pim writes: "A few Lenten Roses (Hellebores) for your table. They are most useful flowers at this dull season, and as hard as nails. E. Muriel Pim was self-sown, and came up with other dark forms round a plant of H. Commenzrenath Benary, which you know is white, with purple flush. By splitting the ends of the stem we find the flowers remain fresh for days when cut."

## NOTES OF THE WEEK.

### FORTHCOMING EVENTS.

February 23.—Royal Horticultural Society's Drill Hall Meeting, 12 noon.

March 8.—Royal Horticultural Society's Drill Hall Meeting. Horticultural Club, House Dinner at 6 p.m. Discussion opened by the Rev. Professor Henslow, on "Botanising Excursions."

March 9.—East Anglian Horticultural Club Meeting.

March 16.—Royal Botanic Society's Flower Show.

March 22.—Royal Horticultural Society's Drill Hall Meeting.

April 5.—Royal Horticultural Society's Drill Hall Meeting.

April 8.—Truro Daffodil Show (two days).  
April 19.—Royal Horticultural Society: Auricula and Primula Society's Show.

**Royal Horticultural Society.**—The prize of £10 offered by the council of the above society for the best essay on "Cottage and Allotment Gardening," has been won by the motto "Observe and Practice," Mr. C. Wakely, of Chelmsford. Owing to unforeseen circumstances the centennial dinner of the society, proposed to be held on March 3, is unavoidably postponed.—W. WILKS, *Secretary*.

**The National Potato Society.**—A meeting of the committee of this new body was, by kind permission, held in the Horticultural Club on Monday last, Mr. A. D. Hall, of Rothamstead, in the chair. The secretary, Mr. W. P. Wright, mentioned a request made that cottage garden societies be allowed to affiliate. This was agreed to, the annual fees being fixed at 5s. for membership not exceeding fifty, and 10s. for all societies having more members. Tenders as invited were received from various firms for the supply of the needful quantity of tubers for some twenty trial plots in diverse parts of the kingdom. The tenders of a northern and a southern firm were accepted, each one to send half the needful quantity. The total required would be about a ton weight. These tubers are to be sent to the various county trial plots direct by the consigners. Many letters offering various forms of advice were read. Generally the objects of the society were heartily approved of. The secretary reported the finances as being in a satisfactory state, so far as trials are concerned. It is hoped in the autumn it may be possible to hold a conference and an exhibition.

**The novel series of prizes at next season's shows of the National Chrysanthemum Society.**—The excellent suggestion that Mr. Cuthbert made on the occasion of the late December exhibition of the National Chrysanthemum Society has been taken up most enthusiastically by the executive committee and friends of that society. It will be remembered that the sum of five shillings is to be offered in numerous instances for the best blooms of certain specified varieties. The blooms are to be selected from those exhibited in the different competitive classes throughout the show, and exhibitors are also to have the opportunity of setting up individual flowers quite independent of existing competitions. The matter was thoroughly

discussed at a recent meeting of the executive committee, and the conclusion arrived at was that given above. Many interested in this novel scheme seem to think that it will now be an inducement to growers who are also exhibitors to bring their very best flowers to the National Chrysanthemum Society's exhibition rather than to retain a certain number of good flowers for other shows. The smaller growers will also have an opportunity of winning some of the prizes, as all stands or exhibits of cut flowers will be inspected for the purpose of ascertaining where the best example of each specified sort is to be found. It was announced that there were no less than 105 prizes of the kind offered, and this is a considerable addition to the already long list.—D. B. C.

**A cosmopolitan gardeners' society in Paris.**—The Société Française d'Horticulture de Londres has for many years done a good work in promoting the interests of young French gardeners in England, and also in a lesser degree of English gardeners going to France. We are very glad to see that a similar society has now been started in Paris. This has for its object the encouragement of special instruction among gardeners, and promotion of friendly intercourse between horticulturists of different countries. Gardeners of all nationalities are eligible for election. It is to be hoped that this society, which, by the way, is entitled "L'Avenir Horticole," will receive the support it deserves, for if rightly managed, and its efforts properly directed, it cannot fail to be of real value and assistance to young gardeners from England and other countries who may wish to spend a short time in France.

**Jasminum nudiflorum.**—In a note in THE GARDEN of the 13th inst. another combination of this plant with *Cotoneaster microphylla* is suggested, as well as the previous one of *Jasminum* and *Ivy*. May I suggest yet another way of using it, and one which I have found by experience to give much winter joy. I have always been eager to increase our winter beauties, as anyone can have a beautiful summer garden, but the real triumph is to carry beauty into winter. I longed to make the *Rhododendron* and other evergreen borders a little brighter, so I planted here and there among them groups of three plants of *Jasminum nudiflorum*. These, as they grew, I left to straggle rather freely among the evergreens, tying up only the tallest branches to a pole kept well out of sight in the middle of each triangle. Between the *Jasmine* I planted large groups of *Lilium croceum*, which later on gave a most beautiful effect as of *Lilies* growing in a large natural basket of tender green *Jasmine*. The *Jasmine* arching freely over the *Lilies* was like the tall handles of a basket, and gave a delightful picture that quite surpassed all I had planned. I wish I could send you a photograph, but, alas! the garden is mine no longer, and only the happy memory left. But let me sound one note of warning. The *Jasmine* and *L. croceum* group should not be among the purplish magenta *Rhododendrons*, as the orange and magenta reds are fiercely discordant, but with white *Rhododendrons* and almost all shades of *Azaleas* they are most harmonious.—A. J. BRYANS, *Woodside, Harrow-on-the-Hill*.

**Begonia Gloire de Sceaux.**—So much attention has of late been directed to Messrs. Veitch's charming hybrids of *B. socotrana* and the ubiquitous *Gloire de Lorraine* that there is danger of overlooking the merits of some other desirable sorts, such as *Gloire de Sceaux*, which for flowering in midwinter and during the early part of the year has few equals; it is also quite distinct from any other. It is of vigorous growth, forming a stout branching specimen, well furnished with ample foliage of a rich bronzy olive hue. For the beauty of its leafage alone it is well worth growing, but when in addition the large clusters of rosy pink blossoms develop, its beauty is, of course, greatly enhanced. It is by no means a novelty, having been distributed in 1887 by M.M. Thibaut et Keteleer, of Sceaux, in France, and announced as a hybrid between *B. socotrana* and *B. subpeltata*. Doubts have been expressed as to the correctness of this, but there can be no difference of opinion as to its merits.—T.

**A pretty combination for the greenhouse.**—I am sending a photograph of a very pleasing arrangement in my small viney. It consists of a group of Arum Lilies and the blue Coleus (*C. thyrsoideus*), which look uncommonly well together. The flowers of the latter are about at their best with me just now, and as the rather lanky and leafless stems are hidden by the foliage of the Arums there could hardly be a better way of arranging them.—S. G. R. [Unfortunately, the photograph was not suitable for reproduction.—En.]

**Potatoes in Ayrshire.**—As is well known, the sea-board parishes of Ayrshire are favoured with a climate which is admirably suited for early Potatoes, and the acreage under these is increasing from year to year. Last season was a late one, and planting was considerably delayed. The open weather experienced in the county this year has caused some of the growers, especially on the Carrick shore, to begin early, and the first planted were on the farm of Girvan Mains on the 11th inst.

**A note from North Wales.**—The weather in this part of the country at the present time is causing grave anxiety. The amount of rain which has fallen here since the 1st ult. is enormous, much more than at this time last year. We have only had eight fine days in 1904. Sowing any kind of seeds or planting, either by farmers or gardeners, is quite out of the question, as the land is sodden, and in many cases under water. The winter has been very mild so far. We have had very little snow and frost. The last heavy rains were very cold, with north-east winds.—J. S. HIGGINS, *Rdg Gardens, Corwen, N. W.*

**University College, Reading.**—Mr. Alfred Palmer, Wokefield Park, Berks, has made a gift to the above college of a site for a new college, and the following munificent donations have been given: Lady Wantage, £10,000; Mr. G. W. Palmer, M.P., £10,000; Messrs. Sutton and Sons, £6,000; Mr. J. Herbert Benyon, £3,000; Mr. G. Herbert Morrell, M.P., £1,000; and Mr. Owen Ridley, £500. At an extraordinary general meeting of the court of governors recently held, the principal (Mr. W. M. Childs) said that it was not alone the munificence of Mr. Alfred Palmer which had earned and which would receive their thanks; it was the fact that in addition to this munificence it came precisely at the moment when it would be of permanent help and value to the institution. It was also his privilege to say that Mr. Martin John Sutton, as head of the firm of Sutton and Sons, had authorised him to say that the firm he represented would present to the building fund of the college the sum of £6,000, payable in three annual instalments.

**The Southern Counties Carnation Society broken up.**—A meeting of the committee of the above society was held on the 9th inst. to receive a statement from Mr. W. Garton, jun., the hon. secretary and treasurer. Mr. Garton, addressing the meeting, said that when he initiated the Carnation Society he hoped and expected that after the first year or two it would be made quite or nearly self-supporting, and considering himself mainly responsible for the formation of the society, he had, in the hope that things would mend, made himself personally liable for the deficits on their show accounts. Unfortunately, after an experience of five shows, his hopes had not been realised, and instead of his liability decreasing it was increasing; every effort to improve the membership had failed, and so he felt he could not continue this responsibility single handed any longer, and therefore he was reluctantly compelled to place his resignation in the committee's hands. Mr. Garton took this step with the greatest regret; he was proud of the shows they had held, which he believed would compare favourably with any Carnation show held in the country, but there was such a thing as paying too much for a hobby. If the society could be continued under new management he would assist it in every way he could, short of taking any responsibility, and would help the funds with a liberal subscription. After a long discussion, during which the meeting learned that business arrangements would compel Mr. Hayter, the assistant secretary, to resign also, it was unanimously resolved to

accept Mr. Garton's resignation with the greatest regret, the warmest thanks of the meeting being accorded to that gentleman for the generous support he had given the society during its six years existence. It was also unanimously resolved that this meeting being of opinion that it will not be possible, under the present circumstances, to make the shows self-supporting, recommend the society should be discontinued from this date.

**Proposed Gardeners' Association.** Mr. A. Dean writes: "Kindly permit me to mention in your columns that the adjourned meeting of gardeners and others interested in the proposed Gardeners' Association will, by kind permission, be held in the room of the Horticultural Club, Hotel Windsor, on Tuesday next, at 2 p.m. sharp, when the sub-committee's report will be presented. There are indications that a good discussion will follow. The meeting must determine whether such an association shall be formed or not, and if formed, define what are to be its aims and objects."

**Edinburgh Botanical Society.**—At a meeting of this society, held in Dowell's Rooms, George Street, Edinburgh, on the 11th inst., Professor Trail presided over a good attendance. A most interesting list of alien plants collected in the Edinburgh district was contributed by Mr. W. Evans, F.R.S.E., and Mr. W. E. Evans. This was accompanied by a number of specimens of the plants, and interesting details of the places where they had been found. As might be expected, few were of garden interest, but among these was *Delphinium Ajacis*. Nearly 300 had been collected in all in 1903, the majority coming from Leith Docks and other situations where grain had been deposited. Mr. W. Evans and Mr. W. Edgar Evans were heartily thanked for their contribution. A similar compliment was awarded to Mr. Alexander Cowan, Penicuik, for an admirable report of the annual excursion of the Scottish Alpine Club last year. This had been to Fort William and Arisaig, which was a very interesting one, although few rarities were met with.

**Forestry at Perth show in 1904.** The special committee of the Royal Scottish Arboricultural Society charged with the Forestry exhibition, in connexion with the Highland and Agricultural Society's show there, have issued the prize list and an invitation to the members of the two societies to contribute. Prizes will be offered as follows: For a collection of three varieties of timber grown in Scotland—Scots Pine, Larch, and Norway Spruce; collection of timber of any other three conifers grown in Scotland; collection of three varieties of timber grown in Scotland—Ash, Oak, and Elm; collection of any other three varieties of timber of broad-leaved trees grown in Scotland; for an approved report on the damage done by insect pests injurious to forest trees, and the measures that have been successfully adopted for their extermination; specimens showing the comparative quality of Larch timber grown on different soils and situations, and the respective ages at which it reaches marketable size and maturity; examples showing the best methods of utilising small wood in the manufacture of fancy wood articles, turnery, wood wool, &c.; for a scientific instrument for expeditiously obtaining the diameter of trees at a given height; and for the best exhibit of timber preserved by any process that is practical and economical.

**The Black Currant Boskoop Giant and the mite.**—Evil times have fallen upon the Black Currant bushes in many gardens, and various remedies have been recommended to bring them into a healthy condition, so far with poor results, as once the mite gets a hold upon the trees it appears impossible to get rid of it. Two years ago we cut our oldest bushes down with the intention of getting clean new growth, but I regret to note that the pest reappears. Though considerably weakened, it is not vanquished. Some may have been more fortunate, and if they can give your readers advice it will be welcomed by many growers, as the loss of these fruits is unfortunate. I can only offer a partial remedy, and that is to plant the new Boskoop. So far it has been proof against the mite. It is yet early days to say whether it will continue proof against the pest;

but it has several good points in its favour. It is a strong grower, more vigorous than some of the older sorts, with larger and longer bunches of excellent flavour. It is late in flowering, so that it stands a better chance of escaping spring frosts. Its freedom so far from the mite should make it a favourite. It is only fair to state that it is well to keep it away from infested bushes when planting a new quarter.—G. W. S.

**Royal Horticultural Society.**—The next fruit and flower show will be held on Tuesday next in the Drill Hall, Buckingham Gate, Westminster, 1—4 p.m. A lecture by Mr. R. Lewis Castle, of the Duke of Bedford's Experimental Gardens, on "Pomology" will be given at three o'clock. At a general meeting of the society, held on Tuesday, the 9th inst., eighty-nine new Fellows were elected, making a total of 261 elected since the beginning of the present year.

**The Royal Horticultural Society's entrance fees.**—The exemption of the class of future Fellows of the Royal Horticultural Society, described as "working gardeners," from the payment of the newly-imposed entrance fee of one guinea renders it needful that a very clear definition should be provided. As at present worded the assumption is that only gardeners employed as "workers" in gardens are exempt. How would such a definition affect gardeners whose work is done, and now exist on other means than by work? How will it affect those employed in the horticultural trade as managers, foremen, or persons who have held such positions, and have retired from them in old age? Will the exemption apply to the gardening amateur, who, all the same, may be a poor man? Is he a "working gardener?" The term used in describing the exempted class does not clearly define what is meant, and it is for that reason the council should issue a clear definition of what class or classes of persons engaged in gardening it is proposed to exempt.—A. D.

**Potatoes at Wisley.**—I am extremely pleased to learn that the council of the Royal Horticultural Society, because of the large numbers of diverse varieties of Potatoes sent in for trial, have resolved to plant these at Wisley, and have an ordinary trial of them there this year. That is very satisfactory, and will lend additional interest to the new gardens, and enable many members of the fruit committee to see the new ground for themselves. I fear it will not be possible to associate with the Wisley trial this year one of the trials of Potatoes proposed to be conducted in different parts of the kingdom by the National Potato Society, but, if the council would obtain small quantities of the same varieties as is proposed to be tested in those trials, the general trial at Wisley would be all the more interesting. The varieties the National Potato Society propose to have severally tried are Up-to-Date, Sir J. Llewelyn, Northern Star, Edward VII., Empress Queen, Evergood, British Queen, Charles Fidler, Ninety-fold, The Factor, Cramond Blossom, Good-fellow, and Scotch Champion.—A. D.

**The early distribution of Chrysanthemum novelties.**—The trade specialists, as a rule, distribute their new Chrysanthemum in fairly good time in the spring. If the novelties are to be represented in good form in the succeeding autumn displays, the plants should be in the grower's possession quite early in the spring, or his chances of a success will be somewhat remote. Too often plants are not ordered until the first batch of novelties is being distributed, and in that case less promising plants, and those, too, that were propagated much later than is desirable, have to be acquired instead. Seeing that the life of a new Chrysanthemum is now so short, each novelty being so soon superseded by better ones, it is important that the most be made of it during the first year of its distribution. Chrysanthemums, like other plants, differ much in character and constitution, and while with some new sorts it may be possible to achieve success with a small plant taken in hand in the spring, with another variety equal in appearance one may fail altogether. A long season of steady growth is much to be desired.—D. B. C.

## THE FLOWER GARDEN.

### CLASSIFICATION OF SWEET PEAS.

**S**WEET PEA growers and lovers alike, who follow the progress of the National Sweet Pea Society, cannot fail to recognise the good work being carried out by the committee of that body in its endeavours to classify aright the numerous varieties now in cultivation, and by publishing the results of its deliberations enables growers to choose the very best varieties to grow in each section. I have been much interested in the lists published in *THE GARDEN* of the 23rd ult., giving the results of the special audit of varieties shown at the National Sweet Pea Society's annual exhibition in 1903.

use also; his list appeared in *THE GARDEN* of the 23rd ult.

In *THE GARDEN* of the 6th inst. Mr. Robert Sydenham indulges in a friendly criticism of Mr. Aldersey's list. I question if there is a grower in England (unless it be Mr. Henry Eckford) who has taken a greater interest in the Sweet Pea than Mr. Sydenham, and in responding to his request that other growers should give their opinions on the respective lists, I wish it to be understood that not for a moment do I claim to be able to produce a better list than either Mr. Aldersey or Mr. Sydenham. But rather to endeavour to prove the almost impossibility of two growers in different parts of the country holding similar opinions as to what are really the best varieties, I will state where my experience makes me agree or disagree with your contributors. In the class for whites,

Dorothy Eckford, Blanche Burpee, and Sadie Burpee I think should stand in the order given. But should a fourth be required Emily Henderson would be my choice in preference to Mont Blanc; the latter variety has proved so weak in constitution with me that I have discontinued growing it. For blush varieties I would choose Duchess of Sutherland and Sensation. Cream-coloured, so called by Mr. Aldersey, or creamy buff by Mr. Sydenham, is a section ignored by the National Sweet Pea Society. Mr. Sydenham's definition is, I think, the more correct; the three varieties standing first in my favour are Agnes Johnson, Gracie Greenwood, and Countess of Lathom; while Lottie Hutchins, as given by Mr. Aldersey, I should put in the class called Fancies (or varieties having more than two distinct shades); it is by far the most beautiful of this section (when true to character). Of the so-called yellows, but better still pale primrose, I should select Hon. Mrs. Kenyon, Mrs. Eckford, and Queen Victoria, leaving out Mrs. Ormesby Gore.

Coming to the pinks, I agree with Mr. Aldersey's selection. I know that many growers, and especially Mr. Sydenham, assert the superiority of Prima Donna over Lovely. This seems strange to me, for Lovely has always been 50 per cent. better with me than Prima Donna. It may be that the heavy soil here or the locality suits it better, but I have exhibited it a great many times, and I think I can say without boasting that I have never in competition seen Prima Donna to equal it. I think Mrs. Dugdale is not to be compared to Prince of Wales, Lord Rosebery, and Her Majesty. I should prefer to place it with Royal Rose in the light rose section, but I do not care for either of these two. I think Mr. Sydenham's description of Miss Willmott as salmon-rose is correct. Lady M. Currie was my favourite here before the advent of Miss Willmott, but the latter has altogether eclipsed the former. It may be possible to obtain a richer colour in Lady Mary, but in size of flower

and in constitution Miss Willmott has no rival. I agree with Mr. Sydenham as to Gorgeous being a bicolor, and in this respect I certainly think the society is not quite fair to this section in lumping them all under one heading. By their system we get Triumph heading this long list of bicolors to the exclusion of Jeannie Gordon (in my opinion the best of them all). The class for crimsons and also that for lavenders occupy a most enviable position; in that we all agree. Strange to say, Captain of the Blues has never appeared to me as a light blue, so I join hands with Mr. Aldersey here. On the other hand, I have always considered Countess Cadogan a light blue, but Emily Eckford by far the best, although rather weak in constitution; while I consider Duke of Westminster the very best in the violet and purple section. I also consider Duke of Clarence a first-class variety. I think Mr. Aldersey is quite fair in classing Dorothy Tennant, Mrs. Walter Wright, and Admiration as mauve varieties, though the first-named is certainly much the darkest. I have always preferred Black Knight to Othello. Captivation I consider the nearest to a magenta that we have, while Lord Kenyon I look upon as rose. Duchess of Westminster is, I think, the poorest variety I have grown.

Wistow Hall Gardens, Leicester. F. J. CLARK.

### DOUBLE DAISIES.

It is in the spring garden in particular that we see the Daisies in the fulness of their beauty vying with the green and variegated Arabis, the Forget-me-not, the Tufted Pansy, the Aubrietia, and other things of dwarf growth. Perhaps many may be inclined to regard the Daisy as commonplace, but at the same time there are many varieties. Here then is an opening for improvement, though it is not easy to see where such may come in when we remember the brilliancy of the old Double Crimson or the purity and size of either The Bride or Snowflake. The last is that with broad, flat petals, and is perhaps the finest white bedding variety. The Bride has flowers of exceptional size, too, and they are produced on stems 9 inches long. Rubens is possibly the old crimson kind above mentioned, and never fails to yield a great display of flowers; the colour is really crimson-scarlet. King of Crimsons is another of very striking colour, and one to be strongly recommended. There are also the Hen and Chickens, which is more curious than pretty, and a variety of crimson-red freckled with white. Apart from these are two others of equal, if not greater, importance, viz., Dresden China and Alice, of which we give an illustration. These are very beautiful forms: the first is a very charming tone of pink, the second of more salmon hue and strongly quilled. Upon more than one occasion at the Temple show and at other times we have greatly admired the fine array of Alice set up by the Misses Hopkins, of Mere, Knutsford, and who, we believe, were the introducers of this excellent variety. Dresden China has also been largely shown by the Misses Hopkins.

It need hardly be said that Daisies will flourish in nearly every sort of soil, and where it is desired to increase largely the stock of any existing kind the plants should be pulled to pieces in spring after flowering is over and bedded out in any good garden soil. How well these things grow in moist and even clay soils is well known, and the fact at least should encourage a freer use of them for bedding and other work in the districts where such soils obtain.

E. H. JENKINS.

### EVERGREEN HOLLIES.

#### ILEX AQUIFOLIUM AND ITS VARIETIES.

**A**MONG all the introductions from other countries and climates that have poured into this country during the last 150 years, our native Holly still holds its own as one of the best, if not the very best, of all evergreens for general use in the gardens of Great Britain. It has not, of course, the gorgeous flower-beauty of the Rhododendron, nor the lofty stature and

A GROUP OF THE SALMON QUILLED DAISY ALICE.

This should prove of great value to intending growers, but I should like to have seen a full revised list of varieties (as given in the society's report) published in *THE GARDEN* at the same time. In compiling this list the committee have arranged the varieties in each section in alphabetical order. I have no doubt they have a good reason for this, but if I may be allowed to say so I should prefer to see the varieties arranged according to their recognised order of merit. Many amateurs cannot afford to grow more than one or two varieties in each section, therefore they would naturally wish to select the very best. The National Sweet Pea Society's lists, being the result of the opinions of a great many growers situated in all parts of the country, should be of the greatest value. Nevertheless, a classification list by so good a grower and exhibitor as Mr. Hugh Aldersey should be of much

plumy grace of many exotic Firs and Spruces, but it is always bright and cheerful in the lustrous, deep green of its foliage, and more especially so in winter, when laden with its bright red fruits. What is, perhaps, its greatest merit is that it will grow in any part of the country, on all but the most arid soils, and almost equally well in shade or full sunlight.

Naturally a tree of the middle size, and attaining from 30 feet to 50 feet in height (Loudon mentions examples 60 feet to 70 feet high), it can still be kept permanently at the size of a small bush a few feet high by pruning. For forming an evergreen hedge it is probably the best of all plants, superior even to the Yew, because it will thrive where that will not. It has sported into numerous and very varied forms. In colour, in shape, and in size of leaf, as well as in habit, one may find almost every form that cultivated plants assume among the garden Hollies. Thirty years ago the late Thomas Moore monographed the varieties of the common Holly in the *Gardeners' Chronicle*, with the help of the leading cultivators of Holly in the United Kingdom. Even at that time he was able to name and classify 150 varieties.

Although, like many monographers, Moore probably over-divided his material and relied too much on unimportant and transient characters, his was a genuine and valuable attempt to classify the garden Hollies. The fine collection of Hollies at Kew is named in almost complete accordance with Moore, and his nomenclature has been followed in the "Kew Hand List." In the following notes a representative fifty varieties are briefly described :

#### VARIETIES OF ILEX AQUIFOLIUM.

*Altaclarensis*.—This is a large-leaved variety, dull green, with regularly-placed spines on the margin. The bark is dull purple. The variety is represented by a good specimen at Kew 25 feet high and 13 feet through.

*Angustifolia*.—A green variety, with small, narrow leaves, marked by the large, weak spines set on portions of the margin. It is of slender elegant habit, and can be distinguished from other varieties of a similar type by a large proportion of its leaves having the terminal one-third without spines.

*Argentea* (the "silver" Hollies).—Under this name are grouped several of the Hollies with white or cream-coloured variegation. They include some of the brightest and most ornamental of all the varieties—*argentea longifolia*; *argentea marginata*, the old silver-variegated Holly; *Argentea medio-picta*, or the "Silver Milkmaid," with a whitish blotch in the centre of the leaf; *argentea pendula* or Perry's Weeping, one of the most beautiful of Hollies both as regards habit and leaf-colouring; and

*Argentea regina*, the "Silver Queen" Holly, probably the best of all the "silver" Hollies, and especially marked by its broad, well-defined border of white on the leaves.

*Atravirens*.—One of the big-leaved Hollies, the foliage being dark, shining green, and stout in texture.

*Aurea* (the golden Hollies).—As in the case of *Argentea*, several of the best variegated Hollies are grouped under this name. *Aurea*

*marginata* may be regarded as the typical golden-variegated Holly; *aurea medio-picta*, the "Gold Milkmaid," is marked by the large irregular yellow patch in the centre of the leaf, and is the counterpart of *argentea medio-picta* among the silver Hollies; *aurea pendula*, or "Waterer's Gold Weeping," a handsome pendulous form, whose leaves have a broad, irregular, but well-defined yellow border; and *aurea regina*, the "Golden Queen" Holly, generally considered the finest of all this group; it is a strong grower, and is richly variegated, the greater part of the leaf being golden.

*Balearica*.—A fine, big-leaved green Holly, with a few irregularly set spines, or occasionally none at all.

*Cumelliaefolia*.—The variety we grow at Kew under this name I regard as the finest of the green-leaved sorts. Of erect, pyramidal habit and quick growing, it has leaves 5 inches to 6 inches long, often entirely without spines and rarely with more than three or four; they are usually less than half as wide as they are long, and of the deepest and most lustrous green. This variety is also known as *laurifolia longifolia*.

W. J. BEAN.

(To be continued.)

## NOTES ON HARDY PLANTS

### THE WINTER ACONITE IN LINCOLNSHIRE.

EVERYONE knows the quaintly beautiful flowers of the Winter Aconite (*Eranthis hyemalis*), each so snugly nestled in the deeply-frilled bracts that surround it as to make a perfect miniature posy in itself, and it might seem superfluous to draw attention to it now, were it not that one can hardly have too many of this earliest of hardy flowers. The Winter Aconite is very accommodating; it

will cover the surface of a bed of shrubs with a carpet of gold and green, is perfectly at home on grass land, thrives very well beneath the branches of large trees, as is shown by the accompanying illustration, and is also worthy of a place in the border proper. In soils that are exceptionally cold and wet the Winter Aconite sometimes dwindles away. In Lincolnshire its value as a market flower is being tested, and we have lately seen flowers offered for sale in the streets of London. Each forms such a dainty buttonhole that probably there will be a good demand for it. T.

### SAXIFRAGA FLORULENTA.

IN the genus *Saxifraga* we have many very beautiful plants, and although the great majority are of the easiest culture, some tax the skill of the grower. Some, too, are difficult to procure from the ordinary sources of supply, and even at a high price are almost unobtainable. Such a species is *S. florulenta*, of which, although expensive, there seems at present to be a considerable stock held in these British nurseries where alpine flowers are largely grown. *Saxifraga florulenta* is such a distinct-looking plant that it is easily recognised if it has once been seen, although it is not possible to put its characteristics into such words as will enable anyone to distinguish it by a written description alone, especially in a genus like this, where the species are so numerous. This remark about the ease with which it can be recognised refers to the plant when out of flower, for, unfortunately, its specific name of *florulenta* (slow-flowering) is too literally correct to please an ardent admirer of Saxifrages in flower. Although we may have *S. florulenta* for a number of years, we may never have the privilege of seeing it in bloom.

It is thus little wonder if those who have described its flowers, and who, like myself, have seen it in bloom, differ in the accounts of their colour. Thus I see them called pale lilac by one, crimson by another, and M. Correvon, who is as likely to have seen it as any one, calls it "d'un beau rose," which, I believe, is as near the colour as we are likely to arrive. They are rarely

A FEBRUARY PICTURE—THE WINTER ACONITE UNDER BEECH TREE IN LINCOLNSHIRE.

produced, so that it is not surprising that so few know this species. The whole plant when in bloom is said to grow from 5 inches to 12 inches high, the flowers being in a raceme, and about half an inch long. The rosette of leaves is a very pretty one, varying from 2 inches or 3 inches to as much as 7 inches across. The spatulate leaves are pale green, and have a more leathery appearance than those of most others of their class. It is, unfortunately, one of the species which die after flowering, so that unless it produces seeds there is every chance of losing it after (if ever) it blooms. Still more unfortunate is the fact that it is not easily cultivated, and I have come across it this winter in a very unsatisfactory-looking condition, even where it was under glass. The most healthy plants I have seen were at the base of a terraced rockery in a dry district, in a half-shaded situation. I am growing it on an east exposure, but a little higher up on the rockery than the others referred to. This is because I am of opinion that in my moist climate there is a possibility of this Saxifrage being too wet if on a lower level.

I have written of this Rockfoal at some length, as it is one which will create a good deal of interest in any garden where it can be successfully cultivated, and, above all, well flowered. I can only add that it comes from the Maritime Alps, where it grows at an altitude of from about 6,000 feet to 7,500 feet. S. ARNOTT.

*Carsethorn, by Dumfries, N.B.*

### BULBOUS IRISES FOR TABLE DECORATION.

FOR some years I have grown several of the dwarf Narcissi in ornamental bowls in fibre without drainage, as recommended by Mr. Robert Sydenham and others, and this season I have tried the experiment with some of the hardy bulbous Irises. For this purpose I chose *I. Heldreichi*, *I. reticulata*, *I. Histrio*, and *I. Histrioides*. These I planted in early autumn in the fibre in tiny bowls the size of a tennis ball, one bulb in each. I was very doubtful of success, but the result has been most satisfactory. *I. Histrio* bloomed first, closely followed by *I. Heldreichi*, while *I. reticulata* is in strong bud, and should be out in a day or two. *I. Histrioides* has failed to flower, and is the only disappointment, but at that I am not particularly surprised, as I have found it a shy bloomer under any conditions. Anything more charming than these little flowers thus grown can hardly be imagined; placed here and there in their dainty little bowls on the luncheon table they cannot fail to be admired by everyone. I say luncheon table advisedly, as their colours and ornamental markings under artificial light, of course, fail to produce the pretty effect that they do by daylight.

*Rye.*

F. HERBERT CHAPMAN.

### THE FRUIT GARDEN.

#### SPRING DRESSING FOR OUTDOOR PEACH TREES.

FOR the benefit of those who grow Peaches on open walls I should like to mention what I have found for some years to be a valuable dressing for Peach and other trees on walls. Especially is this the case where the walls are old and the pointing bad from much nailing year after year, consequently giving good winter quarters for the eggs, &c., of insect pests. Red spider is perhaps the worst insect the Peach cultivator has to contend with. I venture, however, to say that any grower who will adopt the practice I have followed for some years will find little trouble from this dreaded pest.

About the first week in March, or immediately before the opening of the blossoms, I prepare a mixture as follows, using for the purpose of mixing a bucket or vessel that will hold four gallons: First dissolve 1 lb. of soft soap, or carbolic soap would perhaps be still better, in half a gallon of hot water. Six pounds of flowers of sulphur may

be put in the bucket and the soapy water added by degrees, mixing with the hands, so that when sufficient water has been added the sulphur will be of the consistency of thick paint and quite free from any lumps. To this add half a gallon of Bentley's Quassia Extract and one quart of Tobacco water, stirring all well together and adding sufficient water to fill the bucket. Half a gallon of this mixture may be added to three and a half gallons of clear water, and while applying it to every inch of the Peach wall, keep the mixture well stirred with the syringe, otherwise the sulphur will quickly settle to the bottom of the bucket.

I find it a good plan to commence at one end of the wall and syringe behind one, and when the opposite end is reached reverse and do the same. By this means the trees and wall are thoroughly wetted, and when dry will be as yellow as sulphur can make them. A dry, sunny afternoon is the best time for applying the mixture. The quantity mentioned—four gallons—is sufficient to make 32 gallons, and is just enough for our Peach wall 120 yards long and 10 feet high. The proportions for a longer or shorter wall are easily ascertained. I have also found great benefits from the use of this mixture on Plum, Cherry, Pear, and Rose trees on walls. It has the advantage of being absolutely safe in application, is not very expensive, and the benefits are almost incalculable.

*Lathom Gardens, Ormskirk.*

B. ASHTON.

#### RAISING BLACK CURRANT BUSHES.

THE thanks of all who are in any way interested in the culture of the Black Currant, either for private use or for market, are due to you for bringing this subject so prominently before our notice on page 72. I know from experience that no greater mistake can be made than to attempt to grow Black Currants successfully on the stem system. Here, in Norfolk, the Black Currant is largely grown both by the cottager and the market grower, and it is a most remunerative crop. A few of the growers still adhere to the old principle of raising their bushes with stems, and I am sorry to find that some nurserymen still insist on raising them in the same way. I was recently looking over two large plantations of Black Currant bushes. Both were planted four years ago, and both occupy ground in the same field, the soil of which is light, rich, and loamy, and most suitable for growing either bush fruit or orchard trees. The one plantation was made up entirely of bushes with stems or shanks about 12 inches in length; the other was planted entirely with bushes grown from cuttings that were not disbudded at all. The former are now in a most unhealthy condition, and are, in fact, useless, while the latter are strong, healthy, and vigorous, and likely to produce heavy crops of fruit for several years to come. The grower of these bushes told me that the crop taken from the bushes with stems was not more than half the weight of that taken from the other bushes, and the quality was nothing to be compared with it. I was also shown a batch of young plants struck from cuttings not disbudded last season, that were in due course to be planted out this season, and will occupy a twelve-acre field. This will show the confidence the grower has in planting bushes grown from plants that have not been disbudded in the cutting stage. Young plants should be cut hard back the first season. It is a great mistake to leave the shoots of newly-planted bushes long. Encourage all growth from as close to the ground as possible.

T. B. FIELD.

*Ashwellthorpe Hall Gardens, Norwich.*

#### PEAR PASSE CRASSANE.

THE splendid dish of fruits of this Pear shown by Mr. Woodward, Barham Court Gardens, Maidstone, at the Drill Hall last week is opportune, for it serves to remind us of the value of this delicious winter variety. Its best season is January and February. When well grown this Pear is excellent. It is, however, somewhat uncertain, and should be given a good position on a wall. Some of the finest fruits of Pear Passe Crassane that we have seen were shown by Mr. Woodward.

## TREES AND SHRUBS.

### EURYA LATIFOLIA VARIEGATA.

IN commenting on the different plants grown by Mr. Petrick at Ghent (*THE GARDEN*, page 103), mention is made of this *Eurya*, and surprise is expressed that it does not find more favour. The same thought has often struck me, for it is in every way a neat-growing plant, and the foliage is richly coloured, in addition to which it is almost hardy, so that it can be used for decoration in positions where such subjects as *Crotons* and *Dracænas* would soon perish. In general appearance this *Eurya* bears a certain amount of resemblance to a *Camellia*, but the leaves are longer in proportion to their width, and are not quite so thick in texture. Unlike most plants, the variegation does not consist of any regular markings, for the leaves when young present an almost indescribable blending of white, yellow, pink, and green of different shades, but as the leaves mature a good deal of the pink disappears. Even if used in draughty corridors and such places where the plants get covered with dust, the smooth, glossy character of the leaves admits of their being readily cleaned. In the particularly favoured districts of England and Ireland it can be regarded as a hardy shrub, but throughout the greater part of the country greenhouse treatment suits it best. It has been known for forty years or thereabouts, but there is no recorded instance of its flowering till 1894. This happened in Cornwall, and the specimens being submitted to Sir Joseph Hooker he decided that it was not a *Enrya* at all, and named it *Cleyera Fortunei*. As such it was figured in the *Botanical Magazine* tab. 7434. As small plants it may sometimes be seen at the different summer exhibitions used as an edging to groups of shrubs or for similar purposes. It is, however, not only as small plants that it is valuable, but good bushy specimens 4 feet or 5 feet high form striking objects in the conservatory. Propagation by means of cuttings is not a difficult matter, the best cuttings being furnished by the half-ripened shoots on plants that have been grown under glass. A length of about 4 inches is very suitable for the cuttings, which should be dibbled into well-drained pots of very sandy soil, and placed in a close propagating case, kept a little warmer than the cuttings have grown in. Special care must be taken not to allow them to flag before insertion.

H. P.

### ULMUS PUMILA.

SINCE the note on this Elm appeared in *THE GARDEN* last week (page 111) we have had the tree photographed, and refer our readers to the information there published. It is a tree of much interest and beauty.

### SHADE TREES.

(Continued from page 111.)

#### NORWAY MAPLE.

THE Norway Maple appears to be the best Maple we have for street use, though most of the trees I have seen are still comparatively young. Care must be taken to prevent its heading too low and making too dense a shade, but this can be easily done by timely and skilful pruning. Like the Sugar Maple, it suffers from dust and smoke, though not to the same extent, while it endures other street conditions much better, as may be seen by comparing the two species in any of our cities. After the first two or three years it makes a strong and rapid growth, and develops into a shapely tree, well adapted to street use, and free from any serious pests.

#### GINKGO.

The Ginkgo is a new and very promising tree from Japan. There is a fine avenue of them in Washington, and they seem to stand the winter as far north as Boston, where several young trees have recently been planted. At Rochester, the extremities of the lower limbs are often winter killed, and in Northern Germany it cannot be successfully cultivated on account of the severe cold and injury

to its branches from snow. This tree is in many ways an ideal street tree, and is without enemies of any kind. One must wait many years for shade, however, and the form of the tree must be adapted to street use by careful pruning.

The indications are that the Ginkgo will make a valuable addition to our list of shade trees; but experiment alone will definitely determine its value. A new tree often has many advantages in the way of soil and attention which would work wonders if bestowed to an equal degree on some ordinary and less esteemed species; while it might be difficult to say just what effect the vigorous conditions under which many of our city trees exist would have upon the species newly introduced. It is to be hoped that the Ginkgo will not have to suffer all that some other trees have borne.

**ASH.**

The Ash is a rapid grower and practically free from insects and diseases. Its foliage does not appear so early as to exclude the sun from the soil in springtime. The wood is strong and valuable, but the branches are badly deformed by the wind. As its roots lie near the surface, it is adapted to shallow soils. Thus far the Ash has not been very much used in cities. Of the various species of this tree the White Ash is much the best.

**HACKBERRY.**

The Hackberry is another of our common native trees which deserves to be more frequently planted. It is shapely, not choice as to soil, grows rapidly, resists drought, is easily grown from the seed and easily transplanted, and is free from any serious diseases. Various leaf-eaters and gall insects attack its foliage, and its branches are often disfigured by distortions attributed to a gall mite and a powdery mildew, but none of these troubles seriously injure its value as a shade producer nor endanger its life. It is said to be frequently used for shade in the west.

**SWEET-GUM.**

The Sweet-Gum develops rapidly and well in a great variety of soils, and is practically free from insects and fungus attacks. The beauty of its foliage in autumn more than compensates for the extra care required to transplanting and the litter caused by its fruits.

**KENTUCKY COFFEE TREE.**

This tree can be grown only in rich damp soil. I have seen it very rarely in cities, but the specimens I have observed were very handsome, and I think it deserves a trial in soils to which it is adapted.

**ELM.**

The merits of this most popular shade tree are so well known that I need not record them here.

It should not be planted, however, to any great extent in the large cities of the East unless provision is made for regular and thorough spraying and other precautions taken to hold in check its various insect enemies, among which the leopard moth and the imported leaf-beetle are the most destructive. The Elm is adapted to wide streets, and requires deep, moist soil. Its condition in many of our cities is far from satisfactory, and its use as a street tree is in many localities attended with considerable risk. In towns and villages where the leaf-beetle is as yet unknown the Elm is grown with great success.

Other species of Elm are occasionally planted in our cities, but none are equal to the American Elm in general fitness for street use. The Slippery Elm, for example, cannot be used on account of its

mucilaginous bark, which is relished by the small boy as a substitute for chewing gum, and the English Elm, which does well in Berlin and Hamburg, is so greedily attacked by the Elm leaf-beetle when planted here that it is not only useless for purposes of shade, but forms a centre from which this insect easily spreads to neighbouring trees of our own species. Incidentally, the English Elm is sometimes used as a trap tree in working against the Elm leaf-beetle.

**SILVER MAPLE.**

The Silver Maple is a graceful tree of very rapid growth, and possesses many qualities of an ideal street tree, but it is especially subject to injurious scales and is often killed by borers, while its

In the deep good soil of Bonn the Horse Chestnut is a large and splendid tree. In Paris it is abundantly and successfully used for planting places and borders; but on the streets of most cities it loses its foliage early, because of drought and the effects of its numerous enemies, so that it cannot be recommended for general street planting.

**SUGAR MAPLE.**

The Sugar Maple grows more slowly than the Silver Maple, and its branches are not subject to injury from storms. It is likewise free from most insect pests, is easily transplanted, and capable of enduring our severest winters. Unfortunately, however, this beautiful tree does not thrive in cities. Its requirements as to soil and water are unusually exacting, and its foliage is very sensitive to dust and smoke, especially during periods of drought. I have examined the Sugar Maple in many cities, but have not found one in which it was cultivated with uniform success.

**HONEY LOCUST.**

The Honey Locust is a fine tree with many good points, but too thorny for city use, and often killed by locust borers. The side branches also have a troublesome way of going into the windows of houses, and the pods are somewhat objectionable.

**LINDEN.**

The Linden requires an abundance of deep rich soil, and suffers much from gas, from drought, and from insect attacks. It does fairly well in Washington, but is little planted now because of the extra care it requires as regards soil and water. In Berlin, Frankfurt, Hamburg, and Paris the leaves of most varieties of Linden fall prematurely on account of insect and fungus attacks. In Philadelphia a few years ago all the large Lindens were killed by borers. A further objection to this tree is the litter made by its blossoms and fruit.

W. A. MURRILL, in  
*Bulletin of Cornell University.*  
(To be continued.)

ULMUS PUMILA IN THE ROYAL GARDENS, KEW.

branches are liable to be broken by the wind. There are 25,000 trees of this species in Washington, many of which bear injuries received during windstorms. Many also have been headed back on account of their extensive growth, and are now diseased and unsightly. The Silver Maple endures city life very well, and, if it escapes its various enemies, develops into a fine though not a durable tree, and its cultivation is always attended with risk.

**HORSE CHESTNUT.**

In the spring the Horse Chestnut is an object of great beauty; but in late summer or autumn, when the red spider and mildew have completed their ravages, it seems unfit for the streets of any city. It is exceedingly tenacious of life; few other trees have suffered so much and survived the shock.

**CHRYSANTHEMUMS,  
DECORATIVE INCURVED  
VARIETIES.**

ON the occasion of the annual dinner of the National Chrysanthemum Society Mr. Henry Cannell, when responding to a toast, recalled the beautiful form of the members of the Rundle family of incurved Chrysanthemums, the first of which came into existence more than forty years ago. This family of Chrysanthemums is represented by Mrs. Geo. Rundle (white), the parent plant, which the National Chrysanthemum Society's catalogue says was introduced in 1868, and its two sports, viz., Mr. Geo. Glenny (pale yellow) and Mrs. Dixon (golden yellow). Mr. Cannell said it would afford unbounded interest if a class could be created for these old favourites of forty years ago, which appear to have fallen out of the ranks. The Sheffield Chrysanthemum Society is fully alive to the value of these pretty little incurved blossoms, and they have for some years had a class in their exhibitions in which a pair of each of the three varieties above mentioned are freely displayed. This competition is one of the prettiest of the whole show, the number of those entering the competition varying from time to time. I have

seen as many as fifteen boards of blooms set up in friendly rivalry, and to determine the relative positions of the first eight exhibits (eight prizes are given) is no easy task when the blooms are so close to one another in quality. I have often expressed the hope that some of the southern societies would follow suit. The Sheffield people have to set up their blooms of this trio with stems not less than 7 inches or more than 9 inches in length, and the boards are also covered with Moss. In this way the flowers are shown to advantage. A far prettier way of displaying these small decorative incurved blooms would be to set them up in small or medium-sized vases, arranging six, nine, or a dozen blooms of one kind in each vase. Such an exhibit would prove most attractive, and would also serve the purpose of making comparison with the present-day race of incurved Chrysanthemums, which there is reason to believe has deteriorated.

#### JAPANESE CHRYSANTHEMUM GENERAL HUTTON.

This is one of the Chrysanthemums of Japanese origin, and was a leading variety last year. When it was first exhibited in 1901 there were a few enthusiasts who recognised its great merit, and

drooping gracefully, and curling and incurving at the tips; they also possess substance and keep well. The plant is one of easy culture, and those who have seen the blooms regard it as one of the best sorts of 1904. It is an English-raised seedling, and comes from Mr. C. Penford, who has given us many good flowers in recent years, and Mr. Norman Davis of Framfield is to distribute it in the ensuing spring. The National Chrysanthemum Society granted a first-class certificate for this novelty in December, 1902. D. B. C.

#### CHRYSANTHEMUM WINTER QUEEN.

This fine late-flowering Japanese Chrysanthemum was seen to advantage at the Royal Horticultural Society's meeting on the 9th inst. Few sorts, indeed, are so late coming into flower, and this fact, combined with the good quality of the blooms, serves to prove that in the variety under notice we have a distinct acquisition. The flowers are large, having long petals of medium width pleasingly twisted and curled. It is said to be a cross between two well-known white sorts—viz., Mlle. Theresa Panckoucke and Mrs. J. Thompson—and the flowers of the new sort certainly appear to

independent of seasons to a very great extent, and the reason of this is not far to seek; it may be simply explained by the one word "retardation." It has taken some time for horticulturists to find out the great value, so far as they are concerned, of retardation. Long before they took up the matter in earnest men concerned with other industries had recognised its real value, and we became accustomed to the enormous supplies of foreign perishable produce regularly placed on our markets. Now, however, the horticulturist is fully alive to the great possibilities for good that this process of retardation undoubtedly has; in fact, it is not too much to say that when it is more widely practised the supplies of fruit, flowers, and also vegetables will be completely revolutionised. By its aid the farmer and market gardener will be able to store away their fruits in a time of glut and place them on the markets at a more propitious season, thus reaping the benefit of increased prices. At present, in the majority of cases, the fruit has either to be sent to market to realise what it can, or else it is wasted. Sometimes the latter is the better plan, for the prices realised may not pay for the cost of gathering and marketing. This would seem to be one way in which to compete successfully with importations of fruit from abroad, i.e., of course, supposing that fruit culture still continues to increase in this country. At the present time we are at the mercy of exporters from other countries, who are able to send over supplies of fruit to reach this country when they are most needed.

Retardation has made rapid strides in America during recent years, and we have already received importations of soft fruit from the United States, while from the Cape supplies of soft fruit are sent regularly at this season of the year, and they do not appear to suffer appreciably in flavour. However, it is with flowers rather than fruit that we are now concerned, and in this direction—at least, in England—more progress has been made. Where a few years ago it was impossible to obtain such things as Liliums, Lilies, Azaleas, Spiraeas, &c., before the spring, it is now easy to have them all the year round if necessary. It is astonishing how quickly one becomes accustomed to things, and this is illustrated by the fact that now few stop to think that it is remarkable to see these

flowers in the market practically all the year round; yet, but for the introduction and development of retardation, we should have them only in their natural season of blooming and as early as the newly-received bulbs and roots could be forced into flower.

We have not now to wait for importations of the plants above mentioned, for large quantities are annually stored in refrigerating chambers, and the following year are brought out and forced into bloom at whatever season they are required. Strange to say—or, perhaps, if one considers for a moment, it is not so strange, but only natural—these retarded bulbs and roots come into flower more quickly and give equally good, if not better, results than those allowed to develop naturally. Messrs. Thomas Rochford and Sons, Turnford Hall Nurseries, Broxbourne, Herts, have probably the largest and best-equipped refrigerator for horticultural purposes in the United Kingdom,

LILY OF THE VALLEY FROM RETARDED ROOTS IN MESSRS. ROCHFORD'S NURSERY.

subsequent events have proved how true this was. Few of the leading stands in the more important competitions throughout the country have been without one or more blooms of this fine sort, and in many private and trade collections I have seen splendidly developed blooms in large numbers. The plant is a consistent one, and that is saying a great deal nowadays. While talking over the doings of the present season the other day with Mr. Norman Davis, he said that he regarded General Hutton as the finest Chrysanthemum in cultivation. The flowers are very large and full, with long and rather broad florets. The colour is rich yellow, flushed bright red. The plant is strong, and has a splendid habit.

#### JAPANESE CHRYSANTHEMUM BEAUTY OF LEIGH.

This handsome Japanese variety, there is good reason to believe, has come to stay. Bright Buttercup yellow is its colour, and the reverse is a paler shade. The flowers are large, full, refined, and will be regarded as an acquisition to those sorts that have a pleasing finish. The petals are long, and of rather more than medium width,

partake of the characteristics of these two. They are pure white, with the faintest tinge of green in the centre, and large and full. The flower-stem is stiff and fairly strong—in fact, quite strong enough for most decorative uses. D. B. C.

#### LILIES ALL THE YEAR ROUND.

RETARDED LILIUMS AND LILIES OF THE VALLEY IN MESSRS. ROCHFORD'S NURSERY.

**P**ERHAPS the most noteworthy advance in floriculture during recent years—and especially in that branch of it which deals with the culture of flowers for market—is revealed in the fact that seasons have ceased to be the important factor to the horticulturist that they once were. He has, in fact, become

and they are able to store away for future use immense quantities of plants. The principle of retardation is simple. In winter the plants are inactive; they live so gently that the loss in vitality is so slight as to be almost imperceptible. Animation can be suspended for a year or two without difficulty, and it is done by prolonging the conditions of winter—in other words, by cold storage. The boxes of roots are piled up in chambers, entered by thick air-tight doors, and it is strange to go inside. You carry a light, and its gleam is reflected as from a million angles of stalactite. The natural moisture arising from the packages is frozen hard and white on the walls and protrusions. A huge engine is used for the purpose of compressing air till it falls to the temperature required, and then drives it into these rooms. In this way an artificial winter is produced, and the Lily sleeps on heedless of the showers of spring or the summer sun. As far as possible economy is exerted in the use of steam power, and for winter preservation of roots large beds are made up in the open air of a material as closely resembling sand as possible. As long as the weather is hard and cold they remain there as they would in their wild state.

Bringing forward the flowers after they are taken from the refrigerating chamber is quite simple. Firstly, the cases are allowed to stand in a room or shed till they have had time to thaw, which takes about twenty-four hours; then they are planted out in boxes and placed under cover in a hot house, where they speedily begin to grow.

RETARDED LILIUM LONGIFLORUM GROWN FOR MARKET.

Lilies of the Valley from retarded crowns make a good deal of foliage, and this proves very useful to arrange with flowers produced from unretarded roots, for the latter usually give but few leaves. Enormous quantities of roots are stored away in the refrigerator, and the fact that several millions of Lily of the Valley alone are dealt with annually by Messrs. Rochford will give some idea of the vast extent of the business. It will be easily understood that so great an industry

gives employment to some hundreds of people, and, in connexion with this, mention may be made of an admirable institute that was erected for the men by the late Mr. Thomas Rochford, and under their management continues to work splendidly.

It is very remarkable to recall that all the glass and hot houses, all the enterprising gardeners and busy labourers at Broxbourne have been called into existence by the needs of the last two or three decades.

But, now that a start has been made, no one can tell where it will end. A. P. H.

## ROUND ABOUT A GARDEN.

### SPRING'S PROMISE.

**I** DOUBT if a garden is ever quite so perfectly pleasant as on a sunny morning in early February, when the season is well forward. There are days, of course, in full spring when the brilliance of the flowering bulbs, paraded by battalions or deployed in bewildering échelon down a vista of mingling hues, makes a spectacle of blazing splendour, which harmonises well with the full band of the nesting birds and the quick-throbbing joy of life in all the world of Nature. This makes even the old man glad that he has lived to see another spring. There is immeasurable comfort, too, in the glory of a garden in high summer, when the air drowns to the hum of bees and lulls us with the opiate of its myriad perfumes. There is joy again—that tenderest joy which is mixed with sadness

A HOUSE OF RETARDED LILIUM SPECIOSUM IN MESSRS. THOMAS ROCHFORD'S NURSERY.

—in the lingering farewell of autumn to the summer's days of honeyed sloth, when the Dahlias outbloom the Roses, and the Chrysanthemums come bravely forward to cover Nature's retreat with a defiant array of mingled colours.

#### THE CRISIS OF PLEASURE.

But the ecstasy of pleasure is always reached when anticipation is just going to be realised. That thrilling moment when the curtain slowly rises for the promised pantomime is the finest experience of all childhood's Christmas holidays; and so, in the annual drama of a garden, that which we most enjoy is the beginning of the fulfilment of our hopes for the coming year of flowers. Only the clustered purity of the Snowdrops may have come as yet to star the golden carpet which the Winter Aconite had spread beneath the trees for early spring to tread upon, and only the Primroses in the shrubberies bloom as yet with any full assurance that she is already passing that way. But there is enough suggestion in these gracious hints—confirmed by the swelling buds on bush and tree, and by the close-set array of blades of green that mark where the great army of the bulbs is marching to spring's summons—to make one almost hug one's self with glad foreknowledge of joys that are almost here already.

#### ABSENT "STARS."

The music of the birds has not yet the full volume of the triumphal march which heralds the entry of summer after spring, when the air shimmers with bird-notes and the sunlight is gilded as it filters through the haze of tiny winged things upon which the swerving swallows feed. But it is the overture of a familiar and well-loved opera which strikes more gladly on the ear than any of the more splendid later passages; and the earlier welcome of the birds to spring has the greater charm because we know each voice so well. The famous tenor—the nightingale—will come on the stage later and deliver his impassioned solos when all other voices are hushed—when, as we listen to his thrilling outbursts, the sentimental moon seems to melt over a dreamy landscape of dim delight. The cuckoo, whose catchy phrase sums up the whole *motif* of the spring opera of the birds, may not be heard for two months yet. But we can afford to wait.

#### "THE BIRDS ARE SINGING."

Even in later spring, when the nightingale and the cuckoo and all the host of warblers are here, it is not *their* glad chorus of sweet music in the morning which makes us fling the windows wide to hear how beautifully "the birds are singing." Then it will still be, as it is now, the faultless improvisation of the song-thrush, the fluty refrain of the blackbird in his rich contralto, and the wild, bold music of the "stormcock" missel-thrush, with the wheedling pipe of hedge-sparrow and the confident carol of robin, which will fill the shrubberies and coppice with a throbbing harmony that seems all the sweeter because the singers are our very own—the same constant birds which have dared the winter with us, and with us rejoice that spring is almost here.

E. K. R.

## BOOKS.

**Lawns.\***—A smooth and verdant lawn is a constant source of pleasure, and enhances the charm of every flower and shrub in the garden. Messrs. Sutton and Sons are responsible for this statement,

\* "Lawns." By Messrs. Sutton and Sons, Reading. Published by Simpkin, Marshall, Hamilton, Kent, and Co. Price 1s.

and few will be inclined to disagree. This being the case, we see at once the importance of keeping the lawn at its best, which, by the help of the information given in "Lawos," will be rendered fairly easy. Garden lawns, tennis lawns, bowling greens, croquet grounds, &c., are dealt with in this book, and full details are given for their making and subsequent proper upkeep. While the lawn is a most important part of the garden, a great deal of ignorance prevails as to the making of a lawn and keeping it in good condition, even among otherwise experienced gardeners. Messrs. Sutton's publications are full of practical information plainly put, and this book on the lawn and its management is no exception.

## THE KITCHEN GARDEN.

### PEAS FROM MAY TILL OCTOBER.

(Continued from page 122.)

#### SECOND DIVISION.

**H**ERE will be found the cream of the whole family, as many can grow these who have not room for later varieties, and, of course, they are not affected by cold, but later on drought is troublesome. More culture is necessary, that is, in poor soils. The plant must get ample food, deep cultivation, and room to develop. I note the last-named point with more force than usual, for this reason: that when the seeds are sown so that they touch each other in the row it is impossible for the plant to thrive, and they collapse when there is heat or drought at the later period of their growth. I am aware it is not always possible to sow thinly at times; the seed does not germinate freely, and one cannot afford gaps in the row. My advice is to thin the seedlings when they are well above the soil. I have touched upon the importance of deep cultivation, that is, double digging and trenching, doing this work in the winter months, and in heavy or poor land it well repays the cultivator to get out trenches, say, 12 feet to 15 feet deep. Place a good body of manure in the trench, and replace some of the top soil to sow the seed on, and for covering the latter. This plan more concerns the latter part of the main crop, as that is the time the plants need more sustenance. It is an excellent plan for the latest varieties. When dealing with the last named the second and main crop should have an open border fully exposed to the sun, and ample room between the rows. Personally, I favour the medium growers, 4 feet or even less, in this section. There are some grand varieties, but it is far better to grow a dwarf vegetable crop between the main crop and late Peas than crowd the rows together. At least 6 feet should be given the medium growers. There is no loss if the ground is cropped between with such things as come off quickly. The following list can be relied upon for quality and cropping for June and later supplies: Carter's Daisy and Danby Stratagem are splendid; the former has received numerous certificates, and I have never seen it fail. Stratagem also is a variety of excellent flavour; also Model Telephone is good. Prize-winner is a very fine pod, a variety given an award of merit in 1896 and a first-class certificate in 1901. This shows that time is a true test with new vegetables. Others are Dwarf Defiance, Duke of Albany, Eureka, Prolific Marrow, Best of All, and the newer Royal Jubilee and Matchless Marrowfat, and, though last in my list, by no means least, should be such fine varieties as Veitch's Main Crop, Autocrat, and the older Perfection, and Laxton's Gradus, and Thos. Laxton, and the new Edwin Beckett, a superior form of Duke of Albany. It will doubtless become a great favourite.

#### THIRD DIVISION.

In this division, which should give a supply from August till cut down by frost, there are many varieties, and, of course, any of the midseason ones sown later are reliable. Should any variety be liked more than others, by sowing every three weeks through May till the end of August there will be a succession; but there must be good culture to battle against heat, drought, and insect

pests. Mildew, also, is troublesome. Some varieties are much less affected than others, and a good deal depends upon the condition of the roots, if starved, crowded, or grown in unsuitable places. In the north it is an easy matter to have good Peas well into November in mild seasons, and in the south I have sown the dwarf first earlies in August for a latest supply on a cool border. In this section comes the well-known Ne Plus Ultra type, one of the best Peas when a true stock can be secured, and fortunately this has been largely used in crossing, so that there are some excellent selections. Gold-finder, Autocrat, Cheltenham—all belong to this family. To this list may be added Sharpe's Queen, a grand Pea; Late Queen, Latest of All, and Windsor Castle. Carter's Latest Marrowfat, known as the Michaelmas Pea, is a splendid dwarf 2-feet to 3-feet variety, and one that resists mildew in the worst seasons. It is only right to add that Peas for stock purposes need the greatest care in sowing, hence the necessity of new blood occasionally, as the older varieties weaken or become mixed.

G. WYTHES.

## CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

### CIDER MAKING IN DEVON.

[TO THE EDITOR OF "THE GARDEN."]

**S**IR,—The subject of cider making in Devon, poetically referred to by Dorothy Hamilton Dean in *THE GARDEN* for the 30th ult., is a question that has so much interest and practical importance at the present time that a few more words in relation to its manufacture may not be out of place.

The beauties of a Devonshire Apple orchard in autumn when the trees are laden with fruit are well described by your correspondent. Unfortunately, however, the crops in this county have for the past two years been small, the last season, indeed, being disastrously so. In the early spring, however, when the numerous orchards are ablaze with the delicate pink flowers, and expectations are rife for an abundant harvest of the staple fruit crop of this county, the sight is even more beautiful, coming as it does after the dreary season of winter. But setting aside the beauties of an Apple orchard, whether in flower or in fruit, one is particularly struck with the condition of the trees in 99 acres out of every 100, showing as they do years upon years of absolute neglect, for most of the orchards have the appearance of having received no attention since they were first planted. The trunks and branches are covered for the most part with a thick growth of Lichen or Ivy, and pruning seems to have been entirely neglected. New varieties, whether for cider making or for domestic purposes, have not been introduced. To remedy this state of things and to make Apple culture, as well as fruit culture in general, a more profitable industry has for some time past occupied the attention of many who have long seen what would happen were these matters not remedied. The Devon County Council also has for some time past instituted lectures and demonstrations on fruit culture, and these are now included in the scheme for higher education under the new Act.

One of the propositions made a short time back with the view of extending the cider industry was that farmers having any extent of Apple orchards attached to their holdings should be instructed in the best methods of cultivation of the fruit and the manufacture of cider. The manufacture of this once-famous drink, however, like everything else, has passed from the primitive conditions which formerly prevailed, and so well described by your correspondent, into one where, in the most modern factories, improved machinery has been introduced and where careful attention is given to every detail, especially in the matter of absolute cleanliness as well as in the selection of special varieties of fruit suitable only for cider making, two of the best varieties being the Sweet Alfred and the Fair

Maid of Devon. In saying this I do not mean that good cider is not made on many well-conducted, old-established farms, but when one sees in abundant Apple seasons heaps of the fruit piled up on the ground in different parts of the orchard till the early winter and then being removed like so much manure in ordinary farm carts to the cider mill, a feeling prevails that cider making at the present time has degenerated now that the beverage is no longer the wholesome, cleanly drink that it was in former days. Indeed, it is now often said that farmers think anything in the shape of an Apple, no matter what variety or in what condition, is good enough to make cider. Then after the pulping process the straw used to place between the layers of pulp was not always free from mildew, so that a musty flavour was conveyed to the liquor.

In modern cider factories the case is very different. If wet weather prevails at the time the Apples are delivered at the works from the orchards, the fruits are cleansed by steam or water jets before being placed in the mill, and when reduced to pulp are submitted to heavy pressure in a screw-press. No straw is used, but layers of pulp are laid alternately with cloths made of Manila Hemp, and upon these are placed frames consisting of strong wooden strips, forming a lattice by crossing each other at right angles. The screw being brought into action soon causes the juice to exude, and it is conveyed into tanks, the sides and bottom of which are glazed so as to ensure perfect cleanliness. As in the primitive system described by your correspondent, no water is added or any other ingredient, the differences in quality and flavour being entirely due to the flavour of the special varieties of Apple used, or by the selection of two or more varieties for blending, for it is said that the cider maker of the present day must study the nature of these varieties and make himself acquainted with the effect the juice of one sort will have when mixed with that of another so that they may be properly blended. From the glazed tanks the liquor is pumped into casks and deposited in well-ventilated cellars, where natural fermentation gradually proceeds under very careful attention as to temperature or chemical changes that may arise, which would spoil the whole of the brewing. Another great object of this operation is to separate impurities from the juice, which arise first to the top in the form of scum and then fall to the bottom, leaving the fluid perfectly clear and bright. When the fermentation is complete the clear cider is drawn off and bottled. That perfection in the manufacture and cleanliness in all the operations connected with cider making at the large factories is aimed at is evident from what I have seen, and it is well that this should be known if cider making is to be resuscitated or developed as an English industry. Ciders of good qualities are to be had, but the prices are, of course, much higher than those of the inferior qualities; but if a real English wine—which is a term now being applied to these best qualities—is required a fair price must be paid for it.

JOHN R. JACKSON.

Claremont, Lympstone, Devon.

## THE POMEGRANATE AS A TUB PLANT.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—I was rather surprised that among the innumerable subjects recommended for tub culture in THE GARDEN, pages 98 and 99, no mention is made of the Pomegranate, which used to be at one time—and probably still is—so well done by Mr. Hudson at Gunnersbury, where tub gardening has long formed a prominent feature. In conversation with Mr. Hudson, who has, I believe, expressed much the same views in one of the horticultural journals, he at one time related a difficulty in flowering them satisfactorily when the plants grown as standards were pruned into shape, but by leaving them alone much better results were obtained. With this treatment the red flowered more freely than the white, but this, I

think, is the general experience under whatever conditions they may be grown. The single-flowered forms, too, are much freer than the double, and are, consequently, better adapted for culture in tubs. The winter treatment accorded to the Myrtles, Lemon Verhena, and similar subjects will just suit the Pomegranate—that is to say, simple protection from frost. Being deciduous they will not need so much water as when in a growing state, but at no time should they be allowed to get too dry. Once established they may be grown in the same tub for years without repotting, providing care is taken in potting them at first. When well rooted an occasional dose of weak liquid manure mixed with soot water is beneficial. T.

## GARDENING OF THE WEEK.

### INDOOR GARDEN.

#### EUCHARIS AMAZONICA.

**A**BOUT this time the plants generally commence growing. To encourage them give a temperature of 65° to 70°, and syringe abundantly. If the plants are doing well do not disturb them; to encourage a free, good growth give them liquid manure—the liquid made from sheep manure is the best—and occasionally give them a dose of weak soot water to impart a good colour to the foliage. The less frequently water is given to their roots the more likely will the plants be to continue in good health.

#### ALLAMANDA HENDERSONII.

Plants that are expected to be in flower by the end of May or early June will have previously been pruned, and probably will have commenced growing. Others required to flower later should now have the previous year's shoots cut back to within one, or not more than two, eyes of the old wood. The earliest pruned will be ready should they require to be repotted, and the compost for such purpose should consist of lumpy fibrous loam, peat or leaf-soil, dried cow manure and sand being added only in very small proportions. Drain the pots well, and over the crocks put a few half-inch bones, and if at the time of repotting the compost be moderately moist water will not be required for some time. Syringe them two or three times daily, and a temperature of 60° to 65° should be afforded.

#### TUBEROUS BEGONIAS.

The bulbs of these that are still dormant will require looking over, and should now be shaken out of the soil in which they grew last year.

It is a good plan, and will economise space, to place the bulbs in shallow boxes among cocoa-fibre or sifted leaf-soil first to start them rooting. Heat is unnecessary at any time, as stronger growths are produced and the plants afterwards grow and flower with greater freedom in a house that is cool and airy. Moisture is at all times essential to their well doing.

It is not too late to raise young plants from seeds, which sow at once, and by the end of August and during September next they should flower abundantly. The bulbs depreciate with age, and as young ones produce finer and better flowers it is advisable annually to raise a few from seeds in order to keep the stock healthy and vigorous.

#### CYCLAMENS.

The young seedling plants will by this time require transferring to 3-inch and 4-inch pots, and these should be clean and well drained. The best position for them afterwards will be near the glass. Give a temperature of 50° at night, with a rise of 5° during the day. Mix coarse sand and bricks broken fine along with equal parts fibrous loam and peat for potting soil.

To keep the leaf-stalks short on all occasions that are favourable admit air, and check the origin of green fly and thrips by fumigating occasionally with XL Vaporiser. It is advisable annually to raise a few plants from seed in order to keep the stock healthy and vigorous. J. P. LEADBETTER.

The Gardens, Tranby Croft, Hull.

## FLOWER GARDEN.

### ROSES.

As a rule, climbing Roses will require but little pruning beyond cutting out all dead branches and a few of the weaker growths. Some of the strong growers, such as Gloire de Dijon, Climbing Devoniensis, &c., that have grown rapidly and left the bottom bare, may have a few of the long shoots bent downwards. These will break freely and cover the bare stems.

The pruning of standards and dwarfs in beds and borders had better be delayed until next month. Most growers have their favourite time for this operation. A very successful grower in the neighbourhood of Exeter used to aver that to prune his Roses before the 7th or later than the 11th of March was to court failure. And undoubtedly the period named was suitable for that locality, but would be too early for less favoured parts of the country. Unless exhibition blooms are required the severe cutting back sometimes practised is to be deprecated, except with some very weakly growers. If some of the long shoots of the dwarfs are shortened back to about 1 foot or 18 inches in length and carefully pegged down to the ground, they will be very effective. The ground was in such a sodden state last autumn—here we had 10·77 inches of rain during October—that any planting in November was out of the question. If it is intended to make new beds this should be done now, so that the ground will have time to settle before planting. Most garden soils will grow Roses, and in Rose planting the chief things to bear in mind are—that the Rose loves a sunny and sheltered aspect; strong growers usually thrive best in strong soils; weaker and more delicate Roses prefer a lighter rooting medium; and that all Roses revel in a rich soil. Any damaged roots should be cleanly severed with an upward cut. The planting should be firmly done and a mulch of some non-manurial material applied. Where necessary a neat stake should be given, and as soon as possible fix a permanent label.

### CAMELLIAS.

The flower buds of the earliest varieties will soon have a touch of colour. I have found that a moderate sprinkling of guano or kainit at this stage greatly improves the flowers. A periodical top-dressing of roughly-chopped fibrous loam mixed with a little peat and leaf-mould will be beneficial. These beautiful shrubs are much hardier than is generally supposed. The chief thing to guard against are rough winds, which bruise the flowers. Where Rhododendrons grow there, as far as soil is concerned, will the Camellia also flourish. A west or south-west aspect is the best, and if the site is a well-drained slope so much the better. Plant about the end of June. For the first winter it will be necessary to give a little protection, such as a good mulching and some twisted hay bands around the main stems, and if any severe frosts are anticipated a mat laid over the plant at night. For out-of-door work the whites should be used sparingly; singles and semi-doubles will give most satisfaction. Probably *Camellia reticulata*, *C. Donckelaeri*, and *C. Contessa Lavinia Maggi* are the three best.

A. C. BARTLETT.

Pencarrow Gardens, Bodmin.

## FRUIT GARDEN.

### MELONS.

THE earliest plants are now making better progress, and as the days lengthen more sun may be expected. They should be encouraged by placing horse manure and leaves round the pots or beds. Keep a steady bottom-heat of about 80°, a night temperature of 70°, with a further rise of 15° on bright days, after the house is closed 5° lower than above in severe weather. Give a little air early in the day on bright days whenever possible, always avoiding draughts. Attend to the setting of the fruit, and endeavour to get as even a "set" as possible. Pinch the shoots at the second leaf above the fruit, and remove all surplus laterals. Melon seeds being plentiful, have young plants in readiness by sowing at intervals of three weeks in 3-inch pots, always planting out from these pots.

Take care never to plant very deeply. Make up new beds of horse litter and leaves, and place turves grass side downwards upon them to form a ridge, about 2 feet wide at base and 12 inches deep, using fairly heavy loam, a sprinkling of wood ashes, and some approved manure. When the soil is well warmed through, plant out 1½ feet or 2 feet apart. Hero of Lockinge and Blenheim Orange are still two of the most reliable varieties.

CUCUMBERS.

These plants should now be given more moisture and frequent light top-dressings as the roots appear on the surface; also a sprinkling of Thompson's Vine Manure. Warm, weak liquid manure should be supplied freely at other waterings. Seeds sown as advised last month will now be making rapid progress, and should be pinched more freely as growth increases. Avoid overcrowding of the growths, and never allow more fruit to develop than the plants can mature. Seeds should be sown and the material (half stable litter and leaves) got in readiness for frames. This should be turned several times before making up the beds. Plants whose fruits are swelling should have a temperature of 65° or 68° at night, with a further rise of 10° on bright days. Keep a sharp look out for fly, and fumigate at first appearance. Continue to introduce later plants as required, and use the syringe freely among them.

FRUIT ROOM.

The mild, wet winter has not been favourable to the keeping of Grapes. The bunches should be frequently examined and decayed berries removed. Refill the bottles when necessary with soft water. Keep the temperature about 45°, and use as little fire-heat as possible; admit a little air on bright days.

Impney Gardens, Droitwich.

F. JORDAN.

KITCHEN GARDEN.

PEAS.

Owing to successive wet no opportunity has yet been afforded to do anything in the kitchen garden in the way of cropping. On the first favourable opportunity the earliest Peas should be sown on a southern border. It is inadvisable to give a selection of sorts, as most gardeners know exactly what suits their particular district. I prefer to start with a good sowing of dwarf sorts, such as American Wonder, Chelsea Gem, and Wm. Hurst. Choose a dry day. A very shallow drill should be drawn, and after sowing a good covering should be given, raising the drills above the surrounding soil. This will preserve them from damage by wet. Should birds be at all troublesome threads stretched zigzag along the rows will be sufficient protection. Should the garden harbour mice, the Peas should be dipped in red lead that has been slightly moistened. In addition to these a sowing of taller varieties should also be made now. On a plot that has been specially prepared for Peas, favourite sorts for this work here are Dicksons' First and Best, Earliest of All, and Gradus; 4 feet between the rows will be sufficient for these sorts. Peas to come into use before those which it is advised to be sown are ready may be had by making a sowing at once under glass. For planting out choose some long narrow boxes, fill them with good soil that has been put through a ½-inch sieve, sow thickly and place in a cool Peach house. Plant out in rows when the Peas are 4 inches high, giving them ample protection from cold winds.

SEA KALE.

A new plantation of Sea Kale should be made at this period. Where a large quantity has been taken up for forcing a corresponding number should be annually replanted. Where roots are being prepared for forcing the largest side roots should be kept for replanting, and cut into lengths of 6 inches or 8 inches. A piece of ground that has been well trenched and manured and not too exposed to the sun will suit this vegetable best. The sets should be planted with the top just below the surface of the ground. When growth has started the shoots may be thinned out to encourage the formation of large crowns. Where the practice of covering and forcing this vegetable in the open is carried out,

the sets should be planted in clumps from six to nine sets in a clump. These may be conveniently covered with an ordinary 10-inch flower-pot. Some of the newer varieties of this vegetable are superior to the old purple sort, as they are pure white and very tender. Continue to keep up supplies in the forcing house. This vegetable at this season starts readily into growth, and should be inspected daily, as it soon becomes useless.

GENERAL REMARKS.

Ground that has been prepared for Onions should be forked up on the first dry day, and every effort made to get it into condition for sowing early next month.

THOMAS HAY.

Hopetoun House Gardens, Queensferry, N.B.

THE ROCK GARDEN.

ROCK GARDEN-MAKING.

XVI.—STABILITY.

MY previous articles on rock gardening dealt exclusively with the arrangement of rocks for general effect. The most important consideration of all must be the construction of rocks with regard to the requirements of the plants that are to be grown on them. But before entering fully into this matter I will briefly consider yet another important factor, namely, stability. Soil and stones newly filled up have a tendency to settle, especially during wet weather, and if due allowance is not made for this the

If a stone of that kind is not bearing tightly on the solid ground, as, for instance, in the case of stone A (illustration No. 1), this may be remedied by driving a wedge-shaped stone (D) firmly between the stone and the soil.

As in rock building, it is desirable to introduce as much change as possible into the work; it may sometimes be desirable to arrange large stones in an overhanging position. In order to be always sure that this overhanging is not carried to a dangerous extent, it will be well to remember a simple rule of gravity as applied to the law of parallel forces, *i.e.*, an overhanging body is perfectly safe as long as an imaginary perpendicular line through the centre of gravity falls within the base on which that body rests. Diagram No. 2 illustrates this. C is supposed to be the centre of gravity of the overhanging stone, E D is the imaginary perpendicular line, and A B the base. The stone represented in the diagram, therefore, would be perfectly secure. But we have to reckon not only with the overhanging stone itself, but also with the pressure of soil behind it. The angle of rest for filled-up soil is, roughly speaking, about 40°. This angle is represented in the diagram by the line H Q. The stone would, therefore, have to bear the weight also of the soil represented by the triangular piece H G I, and to make sure of absolute stability it would be well in this case to insert an extra support (the wedge-shaped stone indicated by a dotted line) at B.

Sometimes it may be desirable to construct an overhanging rock on a larger scale. As a rule such rocks do not admit of being planted with choice things. They are very handy, however, to form a

kind of protecting roof over plants which require little moisture, such as Opuntias, &c. In building such rocks the above-mentioned law of gravity would apply not only to each stone individually, but also to the structure as a whole. Illustration No. 4 will explain my meaning. The long overhanging stone D does not fit well on the foundation stone A. To give it a better bearing the small stones B and C have therefore been inserted and made the stone D perfectly secure. But in order to make the stone D stand also the additional strain of the overhanging stones F and G more

(1.) Section showing the fixing of stones by letting them down into firm ground.

stones may give way and the plants be displaced or ruined.

It is usual when making a rock garden to begin with the soil, that is to say, heaps of soil are thrown up on which the stones are fixed afterwards. Now I consider that this method is entirely wrong. A newly-constructed rock garden, like a newly-built house, can never be safe without a good foundation. My maxim, therefore, is to begin invariably with the stone, and not with the soil, which latter should be filled in behind the stones as the work proceeds. If the foundation stones give way the whole structure is endangered. The foundation stones, therefore, must be so placed that they cannot be shifted from their position by subsequent pressure of soil settling behind them.

One of the simplest methods of effecting this is illustrated by diagram No. 1 (see illustration), which shows, in section, the formation of a small rocky bed. In this case the stones A and B, which would have to bear the pressure of filled-up soil and stones (represented by C) have been sunk into the solid ground (E), which has been excavated for the purpose. Stones thus placed will bear any amount of pressure produced by soil, &c., settling behind them, and this will only make them still firmer.

weight at its lower end is required, and this is represented in my sketch by the stone E and the soil resting above it.

Soil filled in behind the stones must be firmly rammed to prevent settling to any dangerous extent, that it must also be suitable to the particular kind of plants which are to be grown goes without saying. When writing of the arrangement for effect I mentioned that rocks, to look picturesque, should not be too continuous, but be broken here and there by intervening banks of

(2.) Diagram of stone in an overhanging position. N.B. This stone, although overhanging, would be perfectly safe, because a perpendicular line through its centre of gravity falls well within the base A B.

grass, planting, &c. Sometimes it is necessary to have such grassy banks rather steep. If this steepness does not exceed an angle of, say, 40° to 45° I find it is best to set up the front of such a

(3.) The best shape for thick piece of turf for setting up steep grassy banks.

bank with pieces of turf 18 inches or 15 inches long, 1 foot wide, and about 4 inches thick. Such pieces of turf, if cut not square but diagonally, dovetail firmly into each other, and if the first layer of such turves is sunk a little into the ground its stability will be assured. For very steep slopes, however, this method would not be practicable. In such a case it would be best to set up the front of the bank with ordinary pieces of turf cut the usual size, namely, 3 feet long, 1 foot wide, and about 1½ inches to 2 inches thick. By placing such pieces flat, one on the other, and then ramming the soil behind as the front is built up, a much stronger bank will be the result. The drawback is that the green sides of the turf would not show like those of thick turf, but would be buried. As, however, the roots of the grass would be still there, the front of such a bank—though bare at first—becomes covered with green sward very quickly. All kinds of plants may, of course, be put in as the work proceeds, and their roots will give additional stability to such a bank by holding the soil firmly together.

Elmside, Exeter.

## AN HOUR WITH THE HOLLYHOCK.

(Continued from page 124.)

SHOULD the cultivator have the leisure, or be fond of employing himself among his flowers, he will find an ample field for amusement in the crossing of the various kinds with the view of obtaining novelties and improvements. If this end be contemplated we should advise a separate plot to be set apart, however small, that he may carry on his plans unmolested. Other advantages likewise accrue from this arrangement. First, no shading is necessary when growing for seed; it would indeed be injurious. Then the finest varieties may be set together beyond the fertilising influence of the inferior ones. Again, the best situation for obtaining seeds is a warm sunny border, with a rather dry soil; but such is not the most suitable for the production of large handsome flowers. Perhaps we could not raise the question: "What constitutes a good Hollyhock?" more opportunely than at the present juncture; for without a distinct conception on this point much labour in hybridising will, to say the least of it, be but ill-directed.

Before discussing this point, I would offer, for the consideration of my readers, the "Suggestions for the Guidance of Exhibitors," printed by the committee of the Grand Hollyhock Show held at the Surrey Zoological Gardens in August last:

"Quality, rather than the size of individual flowers or length of spike, should be the first point of consideration.

"The petals of the flowers should be of a thick substance, the edges smooth and even.

"The florets forming the centre or ball should be compact, closely set, rising in the middle to the form of a half globe, with a stiff guard petal extending about half an inch around the base, or in proportion to the size of the centre ball, so that the different parts of the flower may have a uniform appearance.

"The arrangement of the flowers on the spike should be regular, not crowded together in a confused mass, nor loosely hanging with open spaces between them, but so disposed that the shape of each may be distinctly seen.

"When the spike is fully blown the uppermost flower should crown or cover the top.

(4.) Diagram explaining the construction of overhanging rocks.

"A few small green leaves projecting between the flowers increases the beauty of the spike.

"As a last point, it is highly important that the colours be bright, strong, and distinct."

Here we have the collective opinion of the principal growers of the Hollyhock in England, both florists and amateurs. It will be observed, the first aim is to enforce the doctrine of quality before quantity; and with this effort we believe all true lovers of the beautiful will sympathise, for if an object is to be pronounced beautiful or perfect in proportion to its size then should we prefer the unwieldy bulk of the hippopotamus to the delicate, graceful, or symmetrical organism of the Italian greyhound. Without objecting to any of the opinions given above we may perhaps be allowed to qualify and more clearly define certain of them. The ball forming the centre of the flower should in no case exceed half a globe, and the smallest flower admissible should be 5 inches in diameter. Open spaces in the flowers termed pockets are highly objectionable. We would not limit the length of the spike, and the longer the foot-stalks, provided they be strong and hold the flower well up to view, the better. In striped, edged, mottled, and shaded flowers, the ground and overlaying colour should be distinct, well defined, and free from all confusion. The guard petals should be flat, of great substance, neither ridged, serrated, nor curled.

We think it will be tolerably evident to all who have a just view of the flower under discussion that the distance of the ideal standard from the existing forms is sufficiently great to offer encouragement to the seedling raiser, and at the same time not so far removed as to be unattainable. The florist requires a stimulus beyond that presented by ordinary forms. And why should not he be permitted to body forth an ideal beauty as well as the

sculptor, the painter, or the poet? And who shall say his object shall not be realised, drawn from the inexhaustible stores of Nature? None, I ween. The florist is no mere dreamer. He may be an ardent thinker; but he is an ardent worker, too, and he has a right to expect a rare though not unattainable success. Yes; reasoning from analogy, he has a right to expect this as the result of labour. Look at what has been accomplished in other walks of floriculture. Compare with the other species the Roses, the Dahlias, the Pansies, which decorate our parterres, and behold there the result of patient perseverance and unremitting skill. If the improvements in these flowers have been less rapid during the last few years, we must remember that they have long lain under the hand of the improver, and, as a consequence, much of the work is done. W. PAUL, F.L.S.

(To be continued.)

## ORCHIDS.

MESSRS. CHARLESWORTH'S NURSERIES, HEATON, BRADFORD, YORKS.

AMONG the numerous changes and developments in horticulture during recent years, none is more pronounced than the number of specialists brought forth. The only drawback is that many owners of gardens, from which a general supply of produce is required, are apt to judge their gardeners by the results of the specialists' work which they see at exhibitions and other places. These thoughts came into my mind very forcibly after a recent walk through the Orchid houses at the above nurseries. My visit was a hurried one, so I shall not attempt a detailed description. The first house I went into was a large span-rooted one, filled from end to end with the finest lot of Odontoglossums I have seen. They were in rude health, as shown by the stiff, long, deep green foliage springing out of the fat, glossy pseudo-bulbs. As it was not the flowering season for this section, few of the spikes had flowers, though it was easy to see that in a few months' time there would be a great display. I counted from thirty to forty open flowers on two or three spikes. I was told there were no secrets in connexion with their culture beyond the facts of giving them a suitable temperature, both as to heat and moisture, and a healthy rooting medium. The former ranges from 50° at night to 55° to 60° in the day. During that period of the year the houses are controlled by artificial heat. The rooting medium is made up of a mixture of one part good peat and the same of partly decayed Oak leaves, the other being of good sphagnum moss, with a base of clean crocks or potsherds as drainage. It is found that they grow best when at a distance of from 2 feet to 3 feet from the roof glass. Under the central stages are numerous cement tanks for catching the rain-water from the roofs, and in all the houses where these are not present the floors are formed of the natural soil covered with clean ashes, which, being kept constantly moist, give off a humidity which the plants evidently enjoy. House after house is full of choice Cypripediums, from the tiny plantlet just emerging into a separate life to good-sized plants of all the newer and choice species and varieties. Amongst others in flower were *C. lathamianum*, *C. albertianum*, and *C. aureum virginalis*.

*C. albertianum* is a very useful decorative sort for producing cut flowers in quantity, having good long spikes in abundance. I was told that some of the up-to-date market florists had already secured stocks of it. In a lean-to house facing west were *Phalenopsis* in variety, but mostly *P. schilleriana*. Their beautifully marbled, clean foliage and healthy young roots prove that they are at least happy in their surroundings. The back wall is covered with a dense mass of *Ficus minima*, and underneath the

open lattice stages on which the pots or pans are standing are other stages covered with a dense mass of *Fittonias* in variety. As is well known, to have these accessories in good health it is necessary to keep them well supplied with water. It appears that since the Philippine Islands passed from the control of the Spanish Government to the Americans there has been more difficulty in getting at the natural home of *Phalenopsis schilleriana*. Under any circumstances, the risk of importing them is somewhat difficult and expensive. There would be nearly 1,000 plants in this batch.

Another large house is full of *Dendrobiums*, mostly of the noble section. Few were in flower, but the well-developed pseudo-bulbs gave promise of a fine display later on. Several others are full of imported *Cattleyas* in all the choicer species and varieties. Amongst them are fine specimen plants. To me the most interesting of all were the several houses full of seedling *Cattleyas*, *Laelio-Cattleyas*, *Sopbro-Laelias*, &c. There are thousands of them in all stages of growth. I did not see an unhealthy plant in the lot.

While claiming to have no special knowledge of Orchids, I have always had a great fondness for *Cattleyas* and the stronger-growing *Laelias*. I think I can see a greater future for them than before. One drawback to their extended culture is the fact that even under good cultural conditions the death-rate of imported plants is a very heavy one. I once heard a gentleman interested in their culture say that to keep your house or houses full of good *Cattleyas* you required to look upon them almost as one does Dutch bulbs, the only difference being to import them triennially instead of annually. This was an extreme opinion, perhaps, but there is much truth in it. With seedlings this is all changed. Looking at the houses of seedlings with all their leaves on one feels certain that, given fairly good conditions of culture, there would be no higher death-rate in the future than amongst, say, exotic Ferns similarly produced. I was told also that, given the demand, there was nothing to prevent their being produced at what may be termed popular prices. Of course, the very choice species and varieties will always command full value. The weedy ones can, as with other things, be thrown away. In THE GARDEN I have noticed descriptions of some of the flowers as exhibited at the Drill Hall, and perhaps before these notes are in print may do so with others. I know of nothing in connexion with horticulture so intensely interesting as watching the development of the flowers, though, of course, there are and will be many disappointments.

Grimston, Tadcaster.

H. J. C.

### DENDROBIUM SPLENDIDISSIMUM GRANDIFLORUM.

OUR illustration shows a form of the above *Dendrobium*, known as the Woodhatch variety. It is one of the best forms of *D. s. grandiflorum* yet raised. It was shown by Mr. Salter, gardener to Mrs. Haywood, Woodhatch Lodge, Reigate, before the Orchid committee of the Royal Horticultural Society on March 8, 1898, when it received an award of merit. Mr. Salter raised this *Dendrobium*, and it may be said to be one of his best seedlings.

### WORK FOR THE WEEK.

#### GENERAL REMARKS.

ATTENTION should be given to the shading of the various Orchid houses to see that they are in good repair. To those beginning the culture of Orchids, and now contemplating a suitable system of shading, I advise that all blinds should be kept well clear of the glass. We find that lath blinds make a good shading, and they have the double advantage over the cotton blinds, in not being adversely affected by the weather in winter to the same extent. When introducing shading this should be taken into account, so that during severe weather in winter they may be used in preference to excessive fire-heat.

#### STAGING.

Proper staging is of vital importance to the well-being of Orchids, besides adding greatly to the

appearance of the houses.

We generally see the plants placed upon an inverted pot on a stage of shingle or some similar material; the system I advocate is that of having a loose staging made up of 1½-inch square laths, either of pitch Pine or good red Deal, unpainted, and raise them to the desired height by means of loose bricks; the staging can then be altered at any time with little trouble, the plants have a free circulation of air amongst them, the lower stage can be damped down far easier, and by introducing a row of small Ferns, intermixed with *Rex Begonias* at the edge, the house may be made far more attractive.

#### PLANTS UNDER STAGES.

The space underneath the stages may be beautified by making a small rockery facing the paths, taking care that it does not interfere with the bottom ventilators and the hot water pipes, or various plants may be planted in the space. I am convinced that the humidity given off by the plants grown underneath the stages is very beneficial to the Orchid. Nothing looks much worse in any house than to see a bare end wall. Cover it with *Ficus repens*. Glass ends may be utilised for growing *Vandates* in the stove house, and in the *Cattleya* and intermediate house the scandent varieties of *Epidendrum*, such as *E. radicans* and *E. o'brieanum*, may be used with good effect.

Gunton Park Gardens, Reigate.

W. P. BOUND.

#### AT THE SALES.

It is always interesting to look in at Messrs. Protheroe and Morris' auction rooms on Fridays, the day of the weekly sale of Orchids. The Orchids in flower make quite a show, and there are always some choice novelties among them. For some weeks past the *Cypripediums* and *Odontoglossum crispum* varieties have been the most conspicuous, but these are now being supplemented by *Dendrobiums* and *Phalenopsis*. On Friday last plants of *Phalenopsis schilleriana* made 32s. 6d. each; a good plant of *P. amabilis rimestadiana*, 52s. 6d.; *P. grandiflora* sold at 10s.; *Laelia anceps sanderiana*, 21s. each; and some at lower prices. A fine piece of *Cypripedium aureum hycanum giganteum* was the most important item of the sale, and this was knocked down for 25 guineas. Some very fine varieties of *Odontoglossum crispum* were offered; one plant made 4 guineas, another over 3 guineas. *Dendrobium nobile virginale*, small plants in flower, sold at 3 guineas; one went a little over this price. A good plant of *Laelio-Cattleya xanthina* × *hardyana* made 70s.; *Cymbidium Lowi*, 34s.; and a good piece of *Vanda Cathartii* sold at 70s. The newly-imported Orchids did not attract much attention, and those sold went at very low prices.

A. H.

## THE INDOOR GARDEN.

### CARNATION SOUVENIR DE LA MALMAISON.

UPON going round a farmer's garden one day last autumn a border against the north end of the house was noticed to be filled with large, healthy plants of this *Carnation*, and an agreement was made with their owner, with the result that we layered the whole of their growths and had what we wanted of the young plants in

DENDROBIUM SPLENDIDISSIMUM GRANDIFLORUM.

return for our trouble. The robust character of the parent plants was really striking, especially when the wet season was taken into account, and they had occupied their position for two seasons. This can apparently only be attributed to the soil that the plants were grown in. It was an alluvial sandy loam from near a disused forge, and incorporated with burnt refuse therefrom. Some successful cultivators of Malmaison Carnations are particularly careful to keep their plants protected at all times from rain, and one of them once told me that he never permitted his plants to be exposed to mist, as rust might be caused from the foliage becoming wet, and his success proves that his management admirably suits the plants' requirements. The plants that have been referred to, however, were fully exposed. Notwithstanding, they were, as their offspring are at the present time, without a trace of rust. Nevertheless, I should be loth to recommend anyone to expose a collection of Malmaisons, that they grew for flowering in pots and propagating from, to the elements, even during the summer months. We strictly guard against our plants, both old and young, getting in any way wet overhead. It would, all the same, be instructive and interesting to me to know what other growers have to say about this matter, for it appears, judging from the above facts, that there is more than one royal road to success even with the Malmaison *Carnation*.

T. COOMBER.

The Hendre Gardens, Monmouth.

### THE CANTERBURY BELL IN POTS.

CAMPANULA MEDIUM, being biennial, should be sown early in the spring. It is necessary to guard against damp, as when sown thickly in pans in a warm house the plants soon damp off. It is also necessary to sow the seeds evenly to prevent damping, and as soon as the plants are well up remove to a shelf or frame, keeping close to the glass. It is best to secure the seed from a good dwarf strain. I have for years taken much interest in *Campanulas*, and have annually selected the dwarfest plants with good substance in the blooms. I have tried the well-known plan of planting out the seedlings in the summer and lifting into pots in the autumn or early in the spring, but I prefer pot culture, using 7-inch or 8-inch pots, and getting the pots well filled with roots by the late autumn. They will then stand our winters in a cold frame or plunged over the rims of the pots on a sheltered, well-drained border, as they suffer more from damp than cold.

We usually sow in a temperature of 60° in well-prepared soil, and cover with a piece of glass or a hand-light and keep moist. The seedlings are pricked off as soon as ready to handle into 3-inch pots and shifted on as required.

## NOTES FROM THE MARKETS.

### COVENT GARDEN FLOWER MARKET.

**W**E have rarely seen the market present a duller appearance than it did last Saturday. Many of the stands still remain empty. In a chat with some of the growers we learn that the continued wet is causing considerable anxiety. The flooding of stoke-holes renders it impossible to keep fires going in some nurseries, and, should we get a sudden change to frost, things would be very serious indeed. Another great drawback is the difficulty of getting soil fit to use for potting. There are few things more detrimental to spring plants than having to use soil in a bad condition, especially for Mignonette and other fine-rooted plants.

We have now nearly seen the last of the Chrysanthemums for this season, but there are still a few good blooms to be seen. Daffodils are in great plenty, both in pots and cut, and prices are down very low. Lily of the Valley is very good and plentiful. Good pots sell fairly well, and there is some trade for cut flowers, but the supply exceeds the demand. Some good Genistas are now coming in; Marguerites are more plentiful again; Cinerarias sell fairly well, there being few bright-coloured flowers in just now; and red Tulips make better prices than any other colour. There are a few red Roses coming in now, but they are as yet scarce. White Azalea is very plentiful, and sells slowly. Callas, both in pots and cut, continue to be in excess of the demand. Erica willmoreana is now in, and E. hyemalis is getting pretty well finished.

We get very few good Chinese Primulas in now. There is not a great demand for them, but one of the largest buyers told us he could always do with some if they were good enough. Cyclamen continue very good and plentiful. Palms and Ferns are plentiful, and they should now sell better, but growers complain of very dull trade, especially in Palms. In the French market there is now a very large supply, and prices are low, but the hawkers clear out a tremendous lot of this produce.

## OBITUARY.

### MR. ALISTER MURRAY.

**N**ATURE-LOVERS in the Edinburgh district have heard with regret of the death of Mr. Alister Murray, Craigmillar, who took a deep interest in several branches of natural history.

Mr. Murray was an excellent botanist, and made a special study of the Mosses and Liverworts, on which he was an acknowledged authority. He was a keen student of the botany of the Lothians, and his knowledge was evidenced by the splendid collection of the Grasses of the district with which he won a prize offered by the Field Naturalists' Society about two years ago. Among other subjects in which he was an expert was that of bee-keeping, and he conducted classes on this at the Edinburgh School of Gardening for Women at Corstorphine. In many ways Mr. Murray will be much missed among a wide circle of students of natural history, as his help to anyone interested was always freely given. His funeral took place on the 9th inst. Mr. Alister Murray was for some years gardener at Dabton, Thornhill, Dumfriesshire, whence he went to enter upon a similar situation in the employment of Captain Christie, Durie, Leven, Fife. He afterwards went to the Blind Asylum, Craigmillar.

### MR. CHARLES FERGUSON.

DEEP regret has been felt by all who knew him at the death, under painful circumstances, of Mr. Charles Ferguson, nurseryman, Nairn. Mr. Ferguson had been missing since the 8th inst., and two days later his body was found in the river Nairn. It is believed that he had accidentally fallen into the river and been drowned. He was a man of more than ordinary knowledge of several subjects besides gardening. He was an ardent ornithologist, and had a splendid lot of birds' eggs, which he had been collecting for a number of years. He was also a deep student of Celtic history and lore, Scottish history, and several branches of natural history. At the time of his death he was engaged upon a history of Strathardle, Perthshire (his native place), for the Gaelic Society of Inverness, of which he was a leading member, and it was generally recognised that few Scotchmen were so well acquainted with all that related to the battle of Culloden. It must not be supposed that Mr. Ferguson was not interested in his own vocation as a gardener. He filled several situations as head gardener with satisfaction to his employers and credit to himself. He was at Cally, Kirkcudbrightshire, the property of Mr. H. G. Murray Stewart, of Broughton and Cally, and Fairburn, Muir of Ord, Ross-shire, belonging to the Stirling family, previous to starting business. A man of his attainments will be much missed from the ranks of north country horticulturists.

## SOCIETIES.

### ROYAL GARDENERS' ORPHAN FUND.

**I**N the absence of Mr. H. B. May through illness, Mr. Poupart took the chair at the annual general meeting of this fund, held at the Cannon Street Hotel, on the 12th inst. There were some twenty-five persons present, including Messrs. H. J. Veitch, Assbee, J. McLeod, T. W. Sanders, J. Lyne, Cuthbert, George Gordon, Joseph Rochford, and G. Reynolds. Mr. Poupart having said how very sorry they were that Mr. May was absent through illness, and they hope that he will soon recover (a telegram was subsequently sent to Mr. May to this effect), the secretary read the notice convening the meeting and the minutes of the last general meeting.

Mr. Poupart, in moving the adoption of the report, said they had cause for congratulation in that they had been able to increase the disbursements during the past year, although the falling off in subscriptions was to be deplored. Some said that subscribers were lost to the institution because there was no election, but he (the chairman) did not see what difference this could make. The amount of money spent on an election would probably keep an orphan.

Mr. Harry J. Veitch seconded the resolution. He referred to the excellent work accomplished by the Royal Gardeners' Orphan Fund; nearly 200 children had been elected, and £12,000 spent since the fund was established. He thought they ought to be thankful to the late Mr. Penny and his friends for starting it. When a gardener dies young it is impossible for him to save much, and it is especially to young widows that the grants prove so useful. Mr. Veitch concluded by hoping that the orphan fund would continue to flourish. The resolution was carried *nem. con.*

Mr. George Gordon proposed that Earl Carrington be elected a vice-president. Seconded by Mr. Joseph Rochford, and passed unanimously.

Mr. Roupell proposed that Mr. N. N. Sherwood be re-elected treasurer. Seconded by Mr. J. F. McLeod, and carried without dissent.

Mr. Assbee proposed, and Mr. Pearce seconded, a vote of thanks to the auditors, and the re-election of Mr. M. Rowan, the retiring auditor. Passed unanimously.

Mr. R. H. Pearson proposed, and Mr. J. Miles seconded, that Messrs. J. Assbee, W. H. Cuthbert, G. Gordon, J. F. McLeod, T. A. Morrison, and W. Roupell be re-elected members of the committee. Mr. Miles, local secretary of the Southampton Auxiliary, said how much they appreciated the good work of the committee. Carried unanimously.

Mr. J. Assbee proposed, and Mr. Cuthbert seconded, that Messrs. William Bull, R. Hooper Pearson, and W. P. Thomson be elected members of committee in place of Messrs. Peter Kay, G. H. Richards, and George Nicholson who retire. Passed unanimously.

The chairman proposed that Mr. B. Wynne be re-elected secretary, at a salary of £125 per year (an increase of £25). Mr. Miles seconded this proposition, and as a local secretary spoke of the ready help Mr. Wynne always gave. Mr. Roupell supported the resolution, which was carried *nem. con.*

Messrs. Assbee, Cuthbert, McLeod, Lyne, and Reynolds were elected scrutineers of the ballot, on the proposition of Mr. Marshall, seconded by Mr. T. W. Sanders.

**RESULT OF POLL.**—George James Lannas, 367; Harry George Pantling, 361; Reginald Joseph Pantling, 339; Margaret Lannas, 328; Louie Witcher, 230; Mary Elizabeth Pretty, 229; Robert Arthur Pretty, 228; Frank William Sonntag, 214; Henry Gillet, 213; Hilda Blanche Ayling, 186.

### ANNUAL REPORT.

The executive committee, in presenting their sixteenth annual report, congratulates the supporters of the fund on

its continued prosperity and usefulness, as, although from causes too well understood by all, they are but able to show a trifling increase over the previous year's receipts from all sources other than legacies, they have been enabled to increase their disbursements in the form of allowances and grants in aid from £1,692 15s. in 1902 to £1,255 10s. in 1903—a total increase of £162 15s. The committee have to deplore the falling off in annual subscriptions, as shown in the accounts presented, and the more so as the deficiency mainly arises from the non-renewal of 5s. subscriptions; but they hope and believe that when this fact becomes known, and the present dearth of money passes away, these subscriptions will be renewed and increased in number. They cannot believe that those in whose interest the fund was established are indifferent to its claims upon their support. Many there are, undoubtedly, who feel that they cannot subscribe 5s. annually, and these may be usefully reminded that all contributions are voluntary, and that the payment of a subscription one year does not imply that it must be continued in the next.

The committee gratefully acknowledges the receipt of a legacy of £25 from the executors of the will of the late Mr. A. F. Osler of Birmingham, and also the kindly generosity of the Earl of Ilchester in throwing open his beautiful gardens at Holland House on the occasion of the Royal Horticultural Society's exhibition being held there, by which means the fund benefited to a substantial amount. The legacies left to the fund by Mr. A. H. Smeed and Mrs. John Willis, amounting to £350, have been invested in the purchase of £350 12s. 2d. 2½ per cent. Consols. The committee keenly regrets to record the loss which the fund has sustained by the death of two of its founders, Mr. A. F. Barron of Chiswick and Mr. James Smith of Mentmore. Of Mr. Barron's devotion to the fund while its secretary for eleven years it is not possible to feel other than the keenest appreciation, or to speak other than in the highest terms; while of Mr. Smith it may be said that for several years after the establishment of the fund he served on the committee, and until his death was a zealous collector in aid of the charity whose interest he had so warmly at heart.

The number of orphans who have been elected to receive the benefits of the fund during the past fifteen years is 179, and the total amount expended in allowances during the same period is £12,192 17s. 6d. At the commencement of the year the number of children receiving the full allowance was 73, and 24 were added to the list by special resolution at the annual meeting. The number on the fund now is 88, and 10 will be added by election to-day. Most of the candidates have been in receipt of compassionate allowances since their nominations were accepted; and while the committee would have been glad if they could have seen their way to put a larger number than 10 on the fund, prudence dictates the safer course, especially having regard to the fact that as a result of the beneficial alteration made in Rule XIII. at the last annual meeting, they have extended the payment of allowances in some cases for varying periods beyond the fourteen years limit.

The committee again gladly tender their warmest thanks to the local secretaries for valued services rendered, and also gratefully acknowledge the zealously continued exertions on behalf of the fund made by gardening friends in various centres, and could heartily wish that their number could be increased. The annual festival held on May 5, under the presidency of the Right Hon. Earl Carrington, P.C., again proved an unqualified success from every point of view, and as a slight acknowledgment of the committee's appreciation of the noble chairman's kindness on that occasion have the greatest pleasure in recommending that Earl Carrington be to-day elected a vice-president. It has been arranged for the next annual festival to take place at the Hotel Cecil on Tuesday, May 17, and the committee are highly pleased to make the announcement that Sir Trevor Lawrence, Bart., K.C.V.O., President of the Royal Horticultural Society, has most kindly promised to preside on that occasion. As the Royal Horticultural Society will this year celebrate its centenary, it is especially gratifying to the committee that its president should have so kindly accepted their invitation, and trust that all friends of the charity will rally round them in support of so distinguished a patron of horticulture.

The members of the committee who retire by rotation are Mr. J. Assbee, Mr. W. H. Cuthbert, G. Gordon, Mr. J. F. McLeod, Mr. T. A. Morrison, Mr. G. H. Richards, and Mr. W. Roupell; and Messrs. Assbee, Cuthbert, Gordon, McLeod, Morris, and Roupell being eligible, offer themselves for re-election. Mr. G. H. Richards does not offer himself for re-election, and Mr. P. E. Kay and Mr. G. Nicholson having resigned, Mr. William Bull, Mr. R. Hooper Pearson, and Mr. W. P. Thomson are nominated to fill the vacancies thus created. The committee have much pleasure in recording their appreciation of the admirable manner in which Mr. William Sherwood discharges the duties of treasurer on behalf of his father, absent abroad, and in anticipation of Mr. Sherwood's early return, as all hope, in renewed health and vigour, he is again nominated for re-election as treasurer. The committee have again pleasure in thanking Mr. M. Rowan and Mr. P. Randolph Barr for their most careful audit of the accounts of the fund. Mr. Rowan is the retiring auditor, and is nominated for re-election.

### GARDENERS' ROYAL BENEVOLENT INSTITUTION. LIVERPOOL AUXILIARY.

THE third smoking concert arranged by the Liverpool auxiliary was held on the 13th inst. at the Bear's Paw under the most favourable auspices. W. W. Rutherford, Esq., M.P., presided over a crowded audience, and was supported by Messrs. T. Foster, G. Haigh, J. Dickson, N. F. Barnes, H. Middlehurst, B. Ker, J. Guntridge, J. Finigan, E. Ashton, W. Gibbins, A. H. Ardran, B. Cromwell, C. A. Young (chairman of committee), A. J. Crippin (treasurer), R. G. Waterman (secretary), and others.

The chairman, who was accompanied by Mrs. Rutherford, gave a stirring and admirable address on the advantages and claims of the institution, urging that it was necessary for all

classes of men to band themselves together for mutual help in time of need and old age, and commended the workers of the local branch for their diligence and zeal in helping forward the good work in this district. A strong appeal was made for more liberal help, so that the many deserving cases could be assisted, which at present was impossible owing to want of funds. To the younger persons present some valuable advice was tendered that they might avail themselves of the many educational advantages now at their disposal, so that when the duty of carrying on the work of horticulture devolved upon them they might be in a position to carry on the work of production and improvement in an even more efficient manner than at present. Mr. R. G. Waterman moved a vote of thanks to the chairman for his admirable address and practical sympathy. He said the Liverpool auxiliary was the youngest and smallest. The first position they could not alter, but the committee hoped that with the aid of ladies and gentlemen and gardeners of the district they might show a greatly improved financial position. Words of appreciation were tendered to Mrs. Rutherford for the great honour that she had conferred upon them by her presence. This was seconded by Mr. H. Middlehurst, and carried with musical honours and prolonged cheering. Mr. C. A. Young, on behalf of the committee, presented Mrs. Rutherford with a beautiful bouquet. Gifts of cut flowers and loans of plants were made by Mr. C. A. Young, Messrs. R. P. Ker and Sons, Messrs. B. Webb and Sons, and others, which added to the general appearance of the room.

#### BRISTOL AND BATH AUXILIARY.

A SPECIAL meeting was held at Chivers' Restaurant on the 12th inst. Mr. W. A. Garaway, occupying the chair, explained the object of the meeting, namely, to consider the advisability of holding a Rose, Begonia, and Orchid show in aid of the institution. Mr. Vallance was invited to explain the position, and remarked on the want of funds to meet the requirements of the Bristol and Bath Auxiliary, and it was felt that the time was opportune to provide some scheme for increasing the income, which at the present time was at a very low mark. They had for several years past been enabled through the generosity of many leading gentlemen of the district, who had allowed their gardens to be thrown open to the public, and by making a small charge to add to their funds, and the auxiliary had also been materially assisted by the Bristol Chrysanthemum Society and the Westbury show by allowing the sale of produce at their respective shows. But notwithstanding this able assistance, they were very short of funds. He (Mr. Vallance) had carefully thought out the matter, and suggested that a Rose show would be the best means of increasing the income of so deserving a charity. He therefore proposed that a show be held for the purpose. He understood that a bazaar in aid of the Winsley Sanatorium was to be held this year at the Zoological Gardens, and it would not be generous of them to hold the show this year in face of that most deserving institution, but he thought it could be done next year. A discussion was invited. Many gentlemen spoke, and on the vote being taken it was unanimously decided to hold the show during the summer of 1905. The question of a guarantee fund was also brought forward, and responded to in a very gratifying way, many gentlemen adding their names to the list of guarantors. An additional committee was elected, and Bristol may now look forward with interest to a floral show which will certainly meet the tastes of all lovers of horticulture.

#### CARDIFF GARDENERS' ASSOCIATION.

A MEETING took place on Tuesday, the 9th inst., at the Grand Hotel. Mr. H. R. Farmer presided. Mr. F. Waller, Cucumber and Tomato grower to Messrs. Norton and Co., Dinas Powis, gave a highly interesting lecture on "The Culture of Tomatoes." Dealing with its history, from which could be easily traced how remarkably rapidly the Tomato had become popular, the lecturer added that home-grown fruits are by far the best, and command the best prices. Medium size Tomatoes find the more ready sale. The debate which followed was enthusiastically taken up. The best thanks of the meeting were accorded Mr. Waller for his splendid lecture.

#### ANNUAL DINNER.

The "Gardeners'" dinner took place at Barry's Restaurant on Wednesday, the 10th inst., at 7.30 p.m., when E. H. Batram, Esq., occupied the chair, supported by the two hon. secretaries (Messrs. H. Gillett and J. Julian), Messrs. H. R. Farmer and T. Malpas, and a large number of the leading gardeners of the district. After an excellent dinner a short toast list was gone through, and several contributed towards the musical part of the programme. A most enjoyable evening was spent, which terminated with a vote of thanks to the chairman, also to the two hon. secretaries, who had done everything possible to make the evening a success.

#### BRISTOL GARDENERS' ASSOCIATION.

A MOST successful meeting of this association was held at St. John's Rooms on Thursday evening last, Mr. E. Poole, F.R.H.S., presiding over a good attendance. The lecturer for the evening was Mr. Powell, acting as representative from the Reading Gardeners' Association. His lecture was entitled "Bouquet Making," and Mr. Powell added much to his able lecture by demonstrating the art of manipulating flowers. He claimed that the floral art was most essential for the gardener to master, and that all young gardeners should endeavour to make themselves perfect as florists. Mr. Powell gave practical demonstrations, forming the foundation of the bouquet, wiring flowers, and arranging them so as to have the most pleasing effect were the main points of his lecture. His bouquet, a very beautiful example of floral art, was passed round the audience. Sprays and button-holes also received attention. A lively discussion followed his lecture, during which he was asked several questions. He was unanimously thanked for his interesting discourse.

#### ROYAL HORTICULTURAL SOCIETY.

##### SCIENTIFIC COMMITTEE (FEBRUARY 9).

PRESENT: Dr. M. T. Masters, F.R.S. (in the chair), Messrs. Michael, Baker, Drury, Veitch, Worsley, Bowles, Saunders, Keeble, and Douglas, Dr. Bidley, Revs. W. Wilks and G. Henslow, hon. secretary; visitor, Mr. J. Hickley.

*Beans defective*.—Mr. Horsley of Winsford, Cheshire, sent some mould in which Beans had been grown under glass, but failed. The Beans were old. It was thought that the soil was too light, with possibly deficient light, and the Beans being old might have been deficient to germinate. Mr. Baker has undertaken to investigate the matter.

*Coloured photographs of Orchids*.—Mr. Hickley, natural colour photographer, of Kelson, Bassett, Southampton, exhibited some very beautiful transparent illustrations of Orchids in their natural colours. They were effected by a special process of Mr. Hickley's on plates sensitive to the primary colours—red, green, and violet; but the special treatment by which the excellent results were secured is not yet patented. It was enquired as to the cost of such for lantern slides. These would be from 5s. 6d. to 10s. 6d. A vote of thanks was given to Mr. Hickley for his interesting exhibitions and description.

*Tropeolum tuberosum as edible*.—Mr. Bowles reported that the result of his trial was that while they were edible, he could not at all recommend them as palatable.

#### DUMFRIESHIRE AND GALLOWAY HORTICULTURAL SOCIETY.

THE annual meeting of this society was held in the Town Hall, Dumfries, on the 8th inst., Mr. R. Service, nurseryman, chairman of the directors, presiding. Mr. R. G. Mann, secretary and treasurer, submitted his annual report, which was considered a satisfactory one, although the bad season had caused increased expense at the time of the autumn show, and the first Chrysanthemum show held by the society had also necessitated some initial expenses not likely to recur. The income for the year had amounted to £384 1s. 3d., while the expenditure was £383 ss. 2d. The report was adopted, and Mr. Mann thanked for his services. The appointment of office-bearers was then proceeded with, and the following were elected: honorary president, the Earl of Mansfield; president, W. J. Herries Maxwell, Esq., M.P. for Dumfriesshire; secretary and treasurer, Mr. R. G. Mann, *Courier and Herald*, Dumfries; chairman of directors, Mr. R. Service, of Messrs. James Service and Sons, nurserymen; vice-chairman, Mr. James M'Gregor, of Messrs. Fotheringham and King, nurserymen; other directors, Mr. S. Arnott, Carsethorn, James Henderson, Elmbank Gardens, Mr. James Kennedy, nurseryman, Mr. K. Mackenzie, Elmbank Gardens, and Mr. J. Learmont, of Messrs. W. Learmont and Son, nurserymen. The chairman and secretary were heartily thanked for their services during the past year. In returning thanks the chairman expressed his gratification at the success of the efforts of the society during the past year. He thought the present directorate had acquired the confidence of the exhibitors and the public, and that, with continued support from these, the difficulties they had encountered in rehabilitating the society had been practically overcome.

#### MANCHESTER HORTICULTURAL SOCIETY.

AT the last fortnightly meeting of this society Mr. Councillor Bentley of Middleton gave an interesting address on the Florist's Tulip. There was a large attendance. Mr. Abraham Stansfield, who occupied the chair, introduced the lecturer as not only an amateur florist of distinction, but the son of an amateur florist.

Mr. Bentley said the Tulip appeared to have been held in estimation for a long time by the Turks, and to have been first procured from them in the year 1554, and grown at Vienna. Conrad Gesner, whose memory was perpetuated in the generic name, *Tulipa Gesneriana*, first saw the Tulip plant at Augsburg in the year 1559. It quickly became popular, and in 1577 made its appearance in England, where it was extensively grown for many years, and a great number of new varieties were raised from seed. Parkinson, writing in 1629, enumerated 140 varieties, and spoke highly of their beauty.

The Tulip continued to be a great favourite in this country until about 1750, when other plants, chiefly American, came into fashion, and in the gardens of the wealthy gradually superseded it. The lecturer paid a worthy tribute to those English florists who have since continued the culture of this beautiful flower, and afterwards proceeded with the descriptive part of his lecture, which was made clearer by the use of coloured diagrams.

In the discussion that followed, Messrs. Elkin, Edwards, Tait, Kay, Paul, Entwistle, and others took part.

#### CROYDON HORTICULTURAL SOCIETY.

THE fourth annual dinner of the Croydon Horticultural Society was held at the Greyhound Hotel, Croydon, on Wednesday evening, the 10th inst., when, despite the weather, there was a good attendance. Mr. J. J. Reid, the president of the society, was in the chair, and was supported by Dr. Brook Ridley, Messrs. L. Stanley Jast, C. H. Curtis, H. Boshier (hon. secretary), P. F. Bunyard (treasurer), and others.

After the usual loyal toasts by the chairman, Mr. C. H. Curtis gave the toast of "The Society." He was glad to see that the society was such a prosperous one. He regretted that there were so many societies in Croydon, as he always considered there was a great waste of energy. They were all working for the same ends, and consequently should combine.

Mr. Boshier, in reply, observed that it was his opinion the three societies were working most amicably together; in fact, the Croydon and District Horticultural Mutual Improvement Society had been described as the nursery of the other societies. In this society every member was

encouraged to voice their feelings and opinions, and the younger members were encouraged as much as the older ones. It was his pleasure to report that the association had had a most successful year, and that it was enabled to carry forward a substantial balance to the ensuing season. They had also held a very successful spring exhibition and an essay competition. The society had instituted a gardeners' registry, and by this means had been enabled to secure a situation for one of its members. Mr. Boshier referred to the great privileges which the society conferred on its members from an educational point of view. He then remarked that for the size of Croydon the society had not so large a membership as it should have, and he appealed to all members of the gardening profession to join their ranks and assist in the mutual improvement for which the society existed.

Mr. Gregory (chairman of the society) proposed "The Kindred Societies." In the course of his well-chosen remarks he pointed out that kindred societies had always been a hobby of his, and he was exceedingly pleased to see so many friends from kindred societies rally round them as they had done that evening.

Mr. W. Gunner, in reply, said no society appreciated the success achieved by this association more than did the Croydon Horticultural Society, and he hoped that it would have still greater aims in the future.

Mr. P. Bunyard, in proposing "The Chairman," compared him to a pilot, which was so necessary to steer ships in dangerous places. The worth of their chairman, he also said, could not be over-estimated.

Mr. Reid thanked them in the warmest terms. He said he had some doubts as to whether he ought to accept the presidency of the society, but he did so because he had once belonged to a mutual improvement society.

#### EAST ANGLIAN HORTICULTURAL CLUB.

THE members who attended the February meeting of this club had a rich treat provided for them by Mr. E. Peake. The subject of the discourse was "The Camera in the Garden," and some splendid slides were thrown upon the screen by a powerful lime-light lantern. Starting with one of our commonest wayside flowers—the Dead Nettle—owing to its curiously constructed blossom first led Mr. Peake to study botany. The large audience were led through many of the gardens familiar to them by repute as the home of choice flowers. There were some charming views of Westwick House Gardens, and in one the head gardener (Mr. G. Davison) was seen explaining the beauties of hardy flowers to a large party of interested excursionists. Mr. Peake has also been to Devonshire and crossed over to the Continent, on each occasion with his camera. The pictures of Continental gardens, with the explanations, were of much interest. Many of the bog plants indigenous to Norfolk were splendidly portrayed also. Mr. Peake further delighted his hearers with an illustrated outline of the career of George Borrow, author of "Lavengro," "The Bible in Spain," &c. This local worthy was a lover of Nature.

A discussi followed, in which Messrs. T. B. Field (Ashwellthorpe), J. Clayton, H. Perry, J. Powley, G. Daniels, and others took part. A hearty vote of thanks was accorded Mr. Peake for his interesting lecture. The monthly competitive tables were well contested, especially in the flower and vegetable sections, Messrs. W. Rush, A. F. Cooke, F. Williams, and R. Abel staging capital pot plants, and Messrs. C. Hines, F. Carrington, and C. Matthews splendid sprouts, Asparagus, and other vegetables. Mr. C. Fox, gardener to Sir Edward Mansel, Bart., Catton House, is able to produce good Camellias in profusion, judging by the display he set up. Several new members were proposed, and the newly-elected Member for Norwich—Mr. Louis Tillet—became an honorary subscriber. The botanical section of the club also continues to hold its fortnightly meetings at the Higher Grade School, Norwich. Recent subjects discussed are: "Cypripediums," opened by Mr. T. B. Field; "Tuberous Begonias," paper by Mr. H. Perry; and "The Vine," introduced by Mr. J. W. Church, Braconash.

#### EALING HORTICULTURAL SOCIETY.

THIS society, which has now been in existence for forty years, and during that time has experienced some changes of circumstances consequent upon wet seasons and other causes, held its annual meeting on the 12th inst. The report of the committee set forth that the weather was propitious on the occasion of the annual exhibition in July last, that there was a good exhibition all round, a large attendance, with the result that the finances of the society had so improved that a debt left over from 1902 had been cleared off and there was a small balance in hand. The adoption of the report and balance sheet having been carried, Mr. R. Dean opened a discussion on the position of the society, by moving an instruction to the committee that the annual meeting be held in the month of January, and the schedule issued in such time that it may be in the hands of the members at least three months before the date of the show. This was seconded and carried. The committee had recommended that the show take place in the Walpole Public Park on July 6. Objection was taken to the latter date on the ground that it clashed with the Henley Regatta week and the annual exhibition of the National Rose Society, June 29 being named as the best date, while it was considered that the show should be held in Gunnersbury Park, Mr. Leopold de Rothschild being the president of the society. Eventually these matters were referred to the committee for decision. Mr. Leopold de Rothschild was re-elected president; Mr. A. G. Dixon, treasurer; and Mr. G. Cannon, secretary. Complaints being made that so few members of the Corporation and of the leading inhabitants supported the society, it was suggested that as all other societies of a social and philanthropic character had annual dinners, that an attempt should be made to hold one by way of calling attention to the claims of the society for support. The matter was referred to the committee to carry out if they thought it desirable to do so.

# THE GARDEN

No. 1684.—VOL. LXV.]

[FEBRUARY 27, 1904.

## FLOWERS, TREES, AND SHRUBS FROM JAPAN.

IT may interest those who love their gardens to think at the present moment, when Japan is, unfortunately, looming large on the political horizon, of the beautiful trees, shrubs, and hardy flowers that have come from that distant land. Illustrations are given on pages 150 and 151 of an Iris garden and a Wistaria bower to show how intensely the love of flowers enters into the life of the people. We owe much to the vast empire of China also for trees and flowers that are, or will be, part of our English woodlands and gardens. In a very interesting article, entitled "Sidelights on Things Japanese," in *Flora and Sylva* of June last, this increasing knowledge of the flora of Japan and China is pointed out, so much so that we have even attempted to imitate in a clumsy way the quaint gardens of Japan, to which allusion is made in the notes accompanying the illustrations on the pages named. "One of the most striking changes," writes Mr. Burbidge in *Flora and Sylva*, "in British gardening of late has been the delight with which we have welcomed the flora of Japan and China. In this welcome the art treasures of both countries have shared more and more, although, as a fact, these were highly valued by connoisseurs long before much interest was taken in Japanese vegetation. The gardening and botanical literature of China and Japan goes back much further than our own, and their modern works are well worthy of special study. No doubt hybridisation and cross-breeding in both countries were effected long ere they found anything like general adoption in Europe, and their very variable races of Lilies, Maples, Chrysanthemums, Adonis, Anemone (Hepatica), Psilotum, Iris, Hemerocallis, Nandina, were originated centuries ago. When Fortune first visited China, about 1843, he took out with him some of our best florist's flowers, and was surprised that they seemed to value nothing he took with him except zonal Pelargoniums! The Japanese were but little more sympathetic, probably because they had so many lovely flowers of their own, and, what is more, so much of sentiment and conventional or legendary lore bound up with them and the seasons at which they naturally bloom. Their

"LOVE OF FLOWERING TREES AND SHRUBS is well known, and the introduction of their Crabs, Cherries, Magnolias, Wistarias, Plums,

and Vines, to say naught of many other choice garden flowers, has given a greater impetus to the planting of flowering trees, shrubs, and climbers in British gardens than any other event of our time. Even Japanese fruits, such as the Plum and the Kaki, are already becoming of much economic interest in California and elsewhere in the warmer United States, in South Africa, Italy, and the South of France. The introduction of the Japanese Chrysanthemum by Fortune, as we all know, led to a great change in the cultivation of that popular flower in our home gardens. To-day the

### "BAMBOO GARDEN

affords another instance of how Japan has helped us in our gardens, and there is reason to believe that these woody-stemmed grasses have been hybridised in that country, but whether as wild or as cultivated in gardens we do not at present know. Take, again, the varieties and forms of the Japanese Maple, and one or two other species, their variation is surprisingly rich, and, so far, we are at a loss to know whether their origin is mainly from seed as wind-fertilised, or whether the custom of grafting, or rather inarching, has not helped in their production.

"As to Cherries and Plums, their name is legion, and the beautiful double-flowered kinds of these are probably of garden origin. The same remark applies to many Lilies, Tree Paeonies, and especially to the artificial rearing of seedling Iris Kämpferi so-called, which are believed to have all come from the purple *I. lævigata* of Siberia. Siebold's Primrose, again, is no doubt a garden development of the Siberian and Chinese *Primula cortusoides*, both having reached Japan *via* China long ago."

The English spring in a woodland planted with the beautiful Plums, Cherries, and other trees from Japan gains in fresh and beautiful colouring. It is interesting to know this at the present moment, but the enthusiasm to imitate

### JAPANESE GARDENING

in these isles is a passing fancy. Fashion is responsible for many horticultural misdeeds. We are *not* Japan, though we owe much to her beautiful flora. A group of Magnolia or Prunus, or whatever the tree, shrub, or plant may be, is beautiful itself, but gardens hedged round with Bamboo canes, intersected with stepping-stones, and planted with the hope of bringing sunny Japan to England are not a delight. We burlesque the real thing.

Mr. Burbidge supports us in his concluding paragraph: "Some of these new Japanese gardens are far from being artistic or from being *Japanese* (the italics are ours), and we believe that they cannot be successfully done except by those who know Japan. . . . What they do in gardens is bound up with their history, geography, and literature, and other things unknown to most who have formed such gardens here."

## PROPOSED NATIONAL GARDENERS' ASSOCIATION.

A PUBLIC meeting was held on Tuesday afternoon to consider the report of a provisional committee as to the advisability of forming an association of private gardeners. This committee has had several meetings, and on Tuesday last presented an outline of its scheme to the public in the form of a resolution. Subsequently an amendment was proposed to the effect that the association be formed of professional gardeners, not private gardeners only. The supporters of the resolution and the amendment were apparently agreed as to the aims and object of the proposed association, but they were at variance upon the matter of restricting membership to private gardeners. Mr. Divers, who moved the resolution, was invited to withdraw the word *private* (gardeners), but could not see his way to do so. Eventually the amendment was carried by a very large majority, and a provisional committee was elected to form a professional gardeners' association. A general meeting will be held later, probably during the Temple show week, to hear the report of this committee. It seems incredulous that out of the head gardeners' committee, who have had the matter in hand, only four should attend the meeting to support their own resolution. If this is to be taken as an indication of their feelings on the subject then it would seem that they are not enthusiastic.

## RAMBLES IN CHILE.

### MANY GARDEN FLOWERS AT HOME.

WE anchored at Coronel at four o'clock on Christmas Day, but decided to defer going ashore till the following morning. Lota, famous throughout Chile for its park and gardens, was the object of our day's excursion, and we intended to go there by a train leaving at eight o'clock. The fates ruled otherwise, for we arrived at the station in time to see the train some two hundred yards already on its way. *Solvitur ambulando*, we set out to do the six miles on foot, following the railway track, which skirts the shore till, cutting

through a headland, the southern boundary of Coronel Bay, it arrives at Lota. We had not gone far before we recognised *Convolvulus Soldanella* and *Nolana paradoxa*, a patchwork of light pink and vivid blue growing in profusion amongst the dark-coloured beach sand. They had as companions a small Spurge (*Euphorbia portulacoides*), in height about 5 inches, with greenish grey foliage and minute dark red inflorescence; also *Polygonum maritimum* and *Salsola Kali*, two widely-distributed beach plants. A little further on we came across *Acacia cavendishii*, not then in flower, but bearing its green pods, which, like the closely-allied species *A. farnesiana*, so often serve as the food of cattle. The prizes of the morning's walk were yet to come. On entering the first cutting I spied, growing on the top, a few spikes of red *Alstroemeria* (*A. Ligtu*). To climb up and pick it was the work of a few seconds. For me it was more than an ordinary find, for had I not from earliest childhood been taught to consider the clumps of red and yellow *Alstroemerias* the pride of the garden at home? Subsequently we found it growing plentifully, the stalks varying from 8 inches (and even not more than 2 inches in the sand near Talcahuano) to quite 2 feet where it had the shelter of a shrub. The variety of tints in the perianth endows this beautiful *Amaryllid* with the charm of a blended colour tone which is peculiarly its own.

The other special prizes of our walk were a giant *Lobelia* of the species *Tupa*, its handsome, erect stems, sometimes as high as 6 feet, crowned with flowers of a rich red, and growing in clumps of six or eight stems, with grey-green, almost rigid leaves. Everywhere it grew in profusion, and was perhaps the most noticeable plant of the district. Another handsome and interesting plant was a *Francoa* (*F. sonchiflora*), nearly allied in appearance and structure to the *Saxifragæ*, a purely Chilean genus, its stems, often 3 feet in length, terminating in a spike of bracteate, rose-coloured flowers. Another plant of which Chile can boast some sixty species was a *Calceolaria*, which decked the banks of the cuttings, bearing its bright yellow clustered flowers on an 8-inch stem. Making a detour over a headland, we found a *Bromeliad*, one of the species *Puya*, with stems 3 feet in height, an *Oenothera* with pale yellow flowers, and some of the pretty blue flowers of a *Godetia*. Here also were many plants of a *Libertia* (*Iridæ*), but we only found one still bearing its small white flowers in a tufted cyme.

As we regained the track the embankments were covered by bushes of a yellow *Lupin*, not indigenous, in full flower. We also noticed a *Dodder* strangling the growth of a shrub (*Griselinia scandens*), with stiff, Laurel-like foliage. Here also was a *Rumex*, carpet-like, with its handsome, dark red flower-spikes, and *Conanthera bifolia* (*Liliacæ*), remarkable for its slender 6-inch stem terminating in a small single flower, with dark mauve petals punctated at their base and markedly recurved, contrasting with the yellow-pointed stamens; the blue *Cichorium Intybus*, introduced by the Spaniards, and now common in Chile; and a small *Flax* (*Linum Aquilinum*), with rich orange-coloured flowers, must be added to the list of our finds.

The afternoon was pleasantly spent in the Lota Gardens, where many species of indigenous and imported trees and shrubs, bright, formal beds of *Geraniums*, &c., a Fern gully, and beautiful views of the Bay of Lota from the high bluff on which the garden is placed make it one of the most beautiful spots in South America.

We were fortunate in finding Mr. Reilly, who has had charge of the gardens for so many years, at home, and, amongst many interesting topics, he told us that he had been, and was at present, very busy in planting the hill slopes near Lota with *Eucalyptus* and two *Pines*—*P. maritima* and *insignis*. The latter, he said, was the more successful of the two, though the thinnings of all three served as pit props for the Lota collieries. He mentioned that 6 feet was not an uncommon growth for the *Eucalyptus* to make in one year, and he also told us that the slit system of planting the seedling trees was exclusively adopted.

RALPH T. HINCKES.

## NOTES OF THE WEEK.

### FORTHCOMING EVENTS.

March 8.—Royal Horticultural Society's Drill Hall Meeting. Horticultural Club, House Dinner at 6 p.m. Discussion opened by the Rev. Professor Henslow, on "Botanising Excursions."

March 9.—East Anglian Horticultural Club Meeting.

March 16.—Royal Botanic Society's Flower Show.

March 22.—Royal Horticultural Society's Drill Hall Meeting.

April 5.—Royal Horticultural Society's Drill Hall Meeting.

April 8.—Truro Daffodil Show (two days).

**Veitch Memorial Medals** have been awarded by the trustees to Mr. Thomas Challis, head gardener to the Earl of Pembroke, Wilton House, Salisbury, and to Mr. John Wright (formerly of the *Journal of Horticulture*).

**Sale of plants at Chiswick.**—On Thursday, March 10, Messrs. Protheroe and Morris will hold a sale at Chiswick of plants grown in the Royal Horticultural Society's Gardens. Included are 250 bush Apples, 100 choice Fig trees, and many greenhouse plants.

**Groups at the Temple show.**—The Arrangements of the Royal Horticultural Society for the year 1904, just received, furnish much interesting reading, and some rules and suggestions regarding the Temple show should effect a greatly needed improvement. First and foremost is the overcrowding of the groups, concerning which we read: "The council desire that (1) all groups should be less crowded, and that (2) masses of colour should be broken up by the use of green foliage. It would be far better if exhibitors would be content to show less and confine it to the best of their produce only. (2) Applies especially to *Azalea mollis*, and to *Tulips*, *Anemones*, and cut flowers generally." This should do something to prevent the marked overcrowding with which we are too familiar, for many of the groups were last year examples of how many plants it is possible to pack within a given space.—H. P.

**"Transactions" of the Scottish Horticultural Association.**—The "Transactions" of this association for 1903, which have just been issued, form a record of remarkable progress and of sound work in the interests of horticulture in Scotland. They contain a list of the office bearers and members; the syllabus of the meetings (to be held in Duwell's Rooms, Edinburgh) for 1904; the constitution, bye-laws, and rules; the report of the Session of 1903 (a model of what such a report should be); minutes of the meetings held in 1903; the papers read at the monthly meetings in 1903; some valuable notes on Mr. Scarlett's Potato growing experiments; and an abstract of the accounts. As a considerable amount of information regarding these has already appeared in THE GARDEN, it is unnecessary to enter at present into further detail regarding them. It is desirable, however, to indicate the subjects of the papers arranged for in the current year. Besides that on "Shrubs," already given by Mr. Whytock, the subjects arranged for are: March 1, "Scottish Plant Names," by Mr. R. P. Brotherston; April 5, "Hardy Fruit Culture as Bearing on the Repopula-

tion of the Rural Districts," by Mr. W. Williamson; May 3, "Flowering Trees and Shrubs," with limelight views, by Mr. George Gordon, V.M.H.; June 7, "Florists," by Mr. J. Grieve; July 5, "Herbaceous Calceolarias," by Mr. C. Comfort; August 2, "Egypt, Palestine, and Greece," by Mr. Peter Barr; September 8, "Stone Fruit on Walls," by Mr. W. Smith; October 4, "Potatoes," by Mr. T. A. Scarlett; November 1, "Chrysanthemums," by Mr. W. Lamont; December 6, "Manuring of Bush Fruits: Insect Pests," with limelight views, by Mr. Shrivell. Excursions will also take place as follow: July 30, Dalkeith Palace Gardens; September 24, Redbraes Nursery; October 1, Hawthornden. The annual subscription is only 2s. 6d., and the secretary is Mr. Peter Loney, 6, Carlton Street, Edinburgh. All Scottish gardeners should be members of this association. It may also be mentioned that the great Chrysanthemum show of the society will be held in the Waverley Market, Edinburgh, on November 17, 18, and 19.

**Coleus thyrsoideus at Glasgow.**—In the public gardens of Glasgow Mr. James Whitton makes great use of this plant for winter flowering, and it is generally much admired by visitors to the fine glass structures which Glasgow is fortunate in possessing in several of her parks. It is cultivated in considerable numbers in the Botanic Gardens also. Few flowers introduced so lately as 1897, as was this *Coleus*, have made such speedy progress as *Coleus thyrsoideus*, and Mr. Whitton was quick to discern its value for winter flowering. Its spikes of blue flowers are most pleasing.

**Sisyrinchium grandiflorum.**—The natural order *Iridæ* furnishes the garden with many an object of interest, the most notable now in flower being *Sisyrinchium grandiflorum*. It is a native of North America, and thrives in almost any soil or position in the rock garden, mixed border, or under a north wall. The albino form is not so easily managed, as it does not possess such a robust constitution; but where properly grown, as with Messrs. House, of Bristol, it is one of the most beautiful hardy plants. It may be propagated readily by division in the early autumn.—W. WALTERS, *Colesbourne Park Gardens, Gloucester*.

**Hardy Heaths in flower.**—The various hardy Heaths, which continue to gain in popularity year by year, have such a long flowering season that there is not a month in the year when they are not in bloom. This is largely owing to the fact that in the case of most of them the individual plants flower continuously for such a long time that the winter, spring, summer, and autumn often considerably overlap. That charming form which, under the name of *Erica mediterranea* hybrida, has within the last six years or so attracted much attention is often well in flower by Christmas, at which season its reddish purple colouring is welcome. Though so long in bloom, it promises to continue for some time yet. The early history of this delightful Heath does not seem to be generally known, but it was, I believe, raised at the Darley Dale Nurseries and distributed from there. Judging by appearances, there is little doubt it is a hybrid between *Erica carnea* and *E. mediterranea*, but on this point the singular fact may be noted that it flowers earlier than either of its parents. Early in the New Year comes the little dense-growing *E. carnea*, or herbacea as it is often called. The bright rosy red flowers are very welcome, but less so those of its variety alba. While this exhausts the list of Heaths that are just now in full flower, there are others whose earliest blossoms are expanding, and, given favourable weather, they will soon make a good show. Of these may be noted *E. mediterranea* and its varieties, as well as *E. lusitanica*, which is better known as *E. codonodes*. This, one of the largest of the hardy members of the Heath family, bears a great profusion of drooping bell-shaped blossoms, in colour white, slightly tinged on the exterior with pink. This is sometimes damaged by severe frosts, but unless much injured it soon recovers. Good-sized bushes of this are very attractive when flowered under glass.—T.

**Gooseberry bushes and caterpillar in winter.**—Last summer was the worst we have experienced for all pests in the garden, and as it is almost impossible when the trees have ripe fruits to cleanse them, much can be done now in getting rid of the pest, and at a season when there is more time to do the work thoroughly. The best remedy I have hitherto tried is to remove the surface soil directly under the trees and cart it away and burn it, and replace with new, at the same time adding a liberal quantity of manure. This done, the trees get the benefit of the new soil and food, and by the removal of old the pest in the surface soil is destroyed. Digging in a good depth would do much good, but this is not possible in many places. I have found it much better to lift the trees if young and replant; then the old quarters can be trenched. Of course this cannot be attempted with old trees, and here I would advise without further delay that a new surface dressing be given after removal of the old soil.—S. H. M.

**Exhibition of spring flowers and Orchids at Dusseldorf.**—In connexion with a grand exhibition of spring flowers, to be held at Dusseldorf from May 1 to May 9, there will be a special show of Orchids on May 1, 2, and 3. Entries close on April 1. All communications concerning Orchid exhibits should be addressed to M. Otto Beyrodt, Marienfelde, Berlin. Many handsome prizes are offered in the various classes for Orchids. For a collection of 100 or more of the finest Orchids in flower (different), the prizes are: First, £50; second, £25; third, £15. There will be other exhibitions of Orchids from September 3 to 6, and from October 21 to 23.

**The flowering of Bamboos.**—Since writing the note, which appeared on page 109, on the above subject I have heard from a friend who lives on the western borders of Devon, that all the clumps of *Phyllostachys Henonis* in his garden are showing flower, so that I fear there is but little doubt that this species will flower generally in the south-west during the present season, a most regrettable circumstance, as this Bamboo is the loveliest of the whole race, and the great clumps, over 20 feet in height, that retained their fresh green throughout the winter, will lose their beauty for at least a year, even if they do not succumb altogether.—S. W. FITZHERBERT.

**Helleborus niger.**—"H. T. M." in his note on the Christmas Rose (page 113), writes: "H. n. maximus bears larger flowers, and is well adapted for forming a succession to the above-named" (*Helleborus niger*). *Helleborus maximus* or *altifolius*, as it is more generally styled, perfects its blossoms before and not after *Helleborus niger*, both the type and the Bath variety. With me it almost invariably commences to bloom towards the end of October, and produces perfect flowers through the whole of November and during the first week in December, but at Christmastide it is useless, and is succeeded by the type and other late-flowering varieties. In a colder climate it would doubtless be later, but I am sceptical of any climatic influences causing it to succeed instead of precede *Helleborus niger*.—S. W. F.

**Colletia cruciata.**—I notice that in writing on this shrub (page 38) Mr. A. C. Bartlett says that it "rarely grows more than 4 feet high." I know many examples that far exceed this height; indeed, specimens 6 feet or more in height are by no means uncommon in the south-west. At Bicton there is an immense shrub, and at the mouth of the river Dart there is one that two years ago was fully 8 feet in height, with a diameter of over 6 feet. This particular example flowers so profusely every November that it appears white with its tiny waxy flowers, which exhale a pleasing fragrance noticeable on fine, still days at some little distance from the bush. A small spray from this shrub, forwarded by me, was illustrated in the pages of THE GARDEN not many months ago.—S. W. F.

**A winter-flowering bedding Viola.** A bedding Viola which will commence to bloom in November and be a mass of blossoms in January and February is an acquisition. Out of some 2,000 plants of Violas growing in the open air this

is the only one in flower, and it occupies one of the most exposed positions in my Hounslow garden. It is the most cheerful subject in the garden, though Daisy and Primrose are struggling to flower. Of singularly dwarf, spreading, tufted growth, the flowers, which are sulphur-yellow in colour, are of good shape and substance, and well displayed above the foliage. I have had this Viola for three years. This year it is floriferous and pleasing to the eye, and I have given it the name of Winter Cheer. I intend to seed from it, and, perchance, may obtain a race of true winter-flowering Violas, continuing on until the earliest of the summer-flowering varieties commence their floral services. Its low, spreading habit of growth fits it for carpeting beds of spring-flowering bulbs, but while, as a rule, the bulbs precede the Violas in the order of blooming, in the case of Winter

ROSE CAROLINE TESTOUT IN A TOWN GARDEN.

Cheer the Viola precedes the bulbs. No special culture whatever has been given it; it blooms in its own good time without assistance of any kind.—R. DEAN.

**Rose Caroline Testout.**—I send you a photograph of Rose Caroline Testout growing in a town garden, in a London suburb in fact, just to show you that it does not appear to mind very much the foggy and smoke-laden atmosphere and other inconveniences of the town garden. There are numerous Roses that will grow well under similar conditions, and Caroline Testout is one of the best of them.—W.

**Horticultural lectures at Altrincham.**—Miss Crooke, assistant at Lady Warwick College, Studley, has arranged to give a course of lectures on horticultural subjects.

The first was attended by about forty ladies, who were much interested. Miss Crooke explained the various methods of digging, double digging, and trenching in a very lucid manner, and also strongly advocated the regular use of the Dutch hoe in dry weather instead of the often ineffectual use of the hose-pipe by ladies. This being rather a venture and an expensive one, it is satisfactory to know that thirty-nine course tickets have already been sold—a sufficient guarantee of the interest taken in gardening pursuits by the ladies of Altrincham and Bowdon. The lectures that are to follow are: "Seed-sowing in the Open Air and Under Glass," "Potting, Planting, and Transplanting," "The Different Uses of the Dibble and Trowel," "Watering," "Feeding," "Mulching," "Walled Gardens and their Purposes," "The Flower Garden," "Different Kinds of Preparation and Formation," "The Rose Garden," "The Herbaceous Border," and "Carnations."

**Royal Scottish Arboricultural Society.—Jubilee Meeting.**—The jubilee meeting of this society was held in Edinburgh on the 16th inst., when there was a large attendance of members. Mr. W. Stewart Fotheringham of Murthly, the president of the society, occupied the chair. The chairman warmly welcomed the delegates from other societies, among these being Mr. A. D. Webster, from the Royal Horticultural Society; Mr. P. Murray Thomson, from the Royal Caledonian Horticultural Society; and Mr. C. Comfort, from the Scottish Horticultural Association. The report of the council, which was submitted by Mr. Galloway, the secretary, was highly favourable. It was stated that there had been a net gain during 1903 of sixty-one members, making the total membership 1,011. Reference was made to the steps being taken by various Scottish public bodies to promote education in forestry; to the arrangements for procuring information about the Larch disease; to the forthcoming forestry exhibition at Perth; to the society's excursion to France in 1904; and various other subjects. The report was adopted, and a motion in support of proposals to establish a State forest demonstration area, trial plots in connexion with Edinburgh University, and a forest school for Scotland was carried. The financial statement, submitted by Mr. Methven, treasurer, was also satisfactory, the total funds at credit of capital account being £1,229 7s. 6d., as compared with £944 17s. 2d. at the close of the previous account. In 1894 the society had only £61, of which £50 belonged to the forestry chair fund. The members then proceeded to elect the office-bearers, Mr. Stewart Fotheringham being re-elected president, and Sir K. J. Mackenzie, Bart., of Gairloch, and Mr. C. Buchanan, overseer on Penicuik, vice-presidents; Mr. Munro-Ferguson, M.P., was appointed hon. secretary, and Mr. R. Galloway secretary and treasurer. Among the members of council are Mr. W. MacKinnon, nurseryman, Edinburgh, and Mr. R. V. Mather, nurseryman, Kelso. The chairman gave a most interesting address in connexion with the celebration of the society's jubilee, in which he traced the history of the society in a lucid and much-appreciated manner; and afterwards Mr. Fraser Story, lecturer on forestry to the Edinburgh and East of Scotland College of Agriculture, gave a paper on "German Forestry"—an admirable address—which was followed by some discussion, generally of a favourable character. In the evening the jubilee dinner took place in the North British Hotel, and was very largely attended. The president of the society presided, and a long toast list was gone through, the speeches being generally eloquent and appropriate. The toast of the evening, that of "The Royal Scottish Arboricultural Society," was proposed by Dr. Somerville, of the Board of Agriculture, and responded to by Mr. Stewart Fotheringham, the president. The whole celebration passed off in a most satisfactory manner, and there is a general opinion that the society, in its efforts to improve Scottish forestry, will be strengthened by this jubilee gathering.

**The Caerphilly Horticultural Society** will hold its annual show this year on August 17.

## EVERGREEN HOLLIES.

## ILEX AQUIFOLIUM AND ITS VARIETIES.

**C**ILIATA and *ciliata major* are distinguished by the long slender spines standing well away from the body of the leaf; the latter is a more vigorous plant than the former, and has larger leaves, but *ciliata* is a neat-habited and pretty variety.

*Crassifolia*.—This rare variety is more of a curiosity than anything else. It has a thin, rather ungainly habit, and the leaves are remarkably thick in texture; they are 2 inches or more long, the body of the leaf about half an inch wide, but set with thick triangular teeth one-eighth to a quarter of an inch long. It is known as "Leather-leaf" Holly, and is represented in the Kew collection by a specimen 10 feet high.

*Crispa* and *crispa picta*.—These two Hollies are distinguished by the curious spiral twisting of the leaves, which are thick in texture, and dull green in *crispa*, but blotched with yellow in *crispa picta*. These two Hollies are sometimes called *tortuosa* and *tortuosa aureo-picta* respectively.

*Donningtonensis*.—A variety of graceful habit, with foliage of a distinct purplish shade of green. The leaves vary in shape, but are usually small and very narrow in proportion to their length; the tooting is very irregular, and sometimes quite absent.

*Ferox* (the Hedgehog Holly).—A curious but not displeasing variety, whose leaves are medium-sized or small, and distinguished by having spines not only on the margins but also clustered on the convex surface. *Ferox argentea* has white spines both at the margins and on the surface, and that part of the leaf from which they spring is also white. *Ferox aurea* has a large blotch of yellow on the leaf, but the spines are green. All three varieties are marked, not only by the formidable armature of the foliage, but also by the recurved margins and "curly" leaves.

*Flavescens* (Moonlight Holly).—Like the common Holly in size and shape of leaf and in habit, this variety differs in the foliage, having a peculiarly soft yellow tinge when young. The colouring is most evident in the youngest leaves, and the older ones become gradually darker. The dark central mass of the bush, with its light yellow-tipped shoots, has quite the effect of a plant lit up by moonlight.

*Fischeri*.—Whilst many of the leaves of this Holly are like those of the ordinary form, only larger, and having bigger and more irregular teeth, others are remarkably distinct in having a narrow triangular shape, and tapering gradually from the truncate base to a fine point, the margins being almost or quite unarmed. The largest leaves are 4 inches long by 2 inches wide.

*Fructu-luteo*.—So far as foliage and habit are concerned this does not differ materially from the common Holly. Its berries, however, are bright yellow, and make it one of the most pleasing and ornamental of all berry-bearing shrubs. Nothing is more beautiful than a well-berried specimen of the common red-fruited Holly in bright weather, but in dull, sunless, or murky weather this yellow-fruited variety is much the more effective.

*Golden King*.—Messrs. Little and Ballantyne, of the Carlisle Nurseries, sent out this Holly a few years ago. It promises to be one of the finest golden-variegated sorts. The leaf is broad and large, not very spiny, with a broad, irregular band of deep gold round the margins. Sometimes more than half the surface of the leaf is golden.

*Handsworthensis*.—I consider this one of the most effective of the silver-variegated varieties. The creamy white margin to the leaf is well-defined, and contrasts well with the purple bark of the younger branches. The leaves are rather longer than in other "silver" varieties, and the variety is known in some nurseries as *argentea longifolia*.

*Hodginsii*.—Of the varieties with large green leaves this is, perhaps, the most popular. It is a vigorous plant, the leaves being elliptical or broadly ovate, and as much as 4 inches long by nearly 3 inches wide; they are of a very dark green, and armed with strong spiny teeth. The bark is purplish. A very useful variety.

*Latispina*.—This striking Holly is not so much grown as one would expect from its distinct appearance and vigorous growth. The leaves are of medium size, but are remarkable in having sometimes none, sometimes as many as six, but usually two or three marginal teeth. These are very large, sometimes twisted downwards, sometimes upwards, and give the leaf a curiously contorted aspect. The apex is drawn out, and tapers to a long, depressed, spiny tooth. The foliage is of a rich lustrous green, and the bark purple.

*Lawsoniana*.—Among the golden Hollies this is noteworthy for the size of its leaves, which are frequently 3 inches to 4 inches long. The centre of the leaf is occupied by a large, irregular blotch of yellow, leaving a green margin varying from one-eighth of an inch to three-quarters of an inch long. This Holly, handsome as it is when in character, has a strong propensity to revert to the green state.

Kew.

W. J. BEAN.

(To be continued.)

## THE FLOWER GARDEN.

## CLASSIFICATION OF SWEET PEAS.

**M**R. ROBERT SYDENHAM'S letter and friendly criticism of my classification of Sweet Peas in THE GARDEN of the 6th inst. has interested me much. Though I cannot pretend to such an intimate knowledge of the merits or otherwise of every known variety of Sweet Pea as Mr. Sydenham possesses, still, like him, I have made a special study of the flower, and have grown the leading named sorts for the past eleven years, and I am gratified to learn that a few at least of my classes are in agreement with his ideas. From my classification enclosed you will see that Dorothy Eckford comes first in the class for whites. Sadie Burpee I put before Blanche Burpee, as with me it is a stronger grower and less affected by rough weather than the latter. Emily Henderson was added, as I explained in the notes sent together with the classification to the secretary of the National Sweet Pea Society last April, "in spite of the objectionable notch in the standard, because it is such a bold flower and strong grower."

I cannot agree with Mr. Sydenham when he says we want no more than three of any one shade of colour, as I consider that every good variety should be included in a classification, especially if the varieties exhibited in a number of classes at the National Sweet Pea Society's show are to be selected from the classification list adopted by the society. Dorothy Eckford and Sadie Burpee would be an ideal pair to exhibit in the class for two whites, one having an upright and the other a hooded standard. Personally, I prefer the upright standards. Mont Blanc I am growing this season, and if it proves worthy it shall certainly be added to my list, perhaps before Emily Henderson. Dainty might be added to the blush class. I still maintain that Mrs. Fitzgerald is a cream-coloured flower. Our rich Cheshire cream is "more or less tinged with buff." Stella Morse I have not grown for some years, but think it might be included in this class. Of Lottie Hutchius I stated in my

explanatory notes: "It certainly is streaked slightly with pink, but the streaks are hardly noticeable, especially if it is grown in partial shade." "Most misleading" sounds rather a harsh term to apply to my yellow class. As Mr. Sydenham says, when "seen at a distance they would be more often called white than yellow." I quite agree with this, but for the purposes of a colour classification we study the flowers closely and not at a distance. The varieties under this heading are the nearest approach we have to a yellow Sweet Pea, and I think that, until we get one resembling in colour a Lent Lily or Tulipa sylvestris, my colour description may stand. Primrose or even pale primrose will not do; besides, I seem to have heard before now of a *yellow Primrose*.

Lady M. (not Mrs.) Ormsby Gore is very similar to, and perhaps hardly an improvement on, Queen Victoria, but for the reasons stated above I think it should be included in the class for yellows. In the pink class Prima Donna is a strong grower, and frequently has four flowers on a stem, but in point of colour has, I think, to give way to Lovely. I well remember some years ago, before Lovely was sent out, walking through Eckford's gardens at Wem, and coming to a row of this variety, when all the ladies of the party exclaimed in one breath, "That is lovely!" Ladies are much better judges of colour than most men, and if they were asked to choose between the two flowers I should not be surprised if nine out of ten selected Lovely as the prettier flower. If varieties of exactly the same shade of colour are wanted in the rose class, they would be Prince of Wales, Her Majesty, and Splendour. Mrs. Dugdale might go into the bicolors, but Lord Rosebery would be left out in the cold.

As regards size, Miss Willmott is superior to Lady Mary Currie, but, as I explained in my notes, the latter was put first in the bright rose class as representing the type. To quote again from my notes: "Many of the varieties under the heading 'Self' are not, strictly speaking, self colours, but when their general effect is a self colour I have classed them as such." This will be a sufficient reply to Mr. Sydenham's criticism of my orange class. If picked to pieces and analysed, Gorgeous will no doubt be found to be a bicolor, or even a tricolor, but the general effect is orange. How does Mr. Sydenham reconcile the inclusion of Royal Rose and Apple Blossom among his selfs with his criticism of my orange class? So great is the divergence of Mr. Sydenham's present classification from that of last year (which I enclose) that on close comparison I am almost tempted to think he has not hesitated to avail himself of several points from my list.

For an explanation of my blue class I must again refer to the notes: "Countess Cadogan is dark blue when it first comes out, but when fully expanded is much lighter in colour, and is not at its best until almost getting over. I have therefore included it in the light blues."

Unless the number of classes is to be increased indefinitely, I cannot see how Mrs. Walter Wright, Dorothy Tennant, and Admirable are to be separated. Perhaps a better name than mauve for this class would be lilac. Othello and Black Knight are so much alike that it seems to be of little consequence which comes first in the list. The former has a slight dusty appearance, reminding one of the bloom on a Grape; the latter has a metallic sheen, as though the bloom had been rubbed off. I prefer the flower with the bloom on.

Gorgeous, Lord Kenyon, and Calypso are mentioned by Mr. Sydenham under the heading of magenta. The first-named is evidently a mistake for George Gordon. When the prevailing colour of a flower is magenta I think it should be put in this class.

Duchess of Westminster certainly is a small, but, none the less, a pretty flower, and when arranged in a vase its ripe apricot effect is very striking. Mr. Sydenham says of this variety that it "sports so much." Sporting is defined as "any deviation from the usual form or colour of a plant or flower." Some Sweet Peas have never been properly fixed, and cannot be depended upon to come true from seed; of many kinds the flowers are apt to run and

become streaky in a cold and damp season; most kinds will occasionally revert or throw back; but of sporting in the strict sense of the term I have never known an instance. The old variety Bronze Prince (not to be confused with Bronze King) occasionally crops up. Last year it appeared among some plants of the Hon. Mrs. E. Kenyon.

I must take exception to the long colour descriptions in Mr. Sydenham's classification, e.g., deep rosy crimson, dark fiery crimson, cerise or dark salmon scarlet, &c. Colour descriptions should, in my opinion, be as clear and concise as possible.

As I have already remarked that, to my mind, ladies are better discriminators of colour than men, would it not be advantageous to get the opinions of those growers among them who like myself take an interest in Sweet Peas, and thereby settle the difficult question of colour classification?

*Aldersey Hall.* HUGH ALDERSEY.

### SCENTED-FOLIAGED GERANIUMS FOR THE SUMMER GARDEN.

THESE, when grown into specimen plants from 3 feet to 6 feet high, and plunged in the turf in groups on the lawn with a background of shrubs or trees, make a charming effect, and are sure to gain much admiration during the summer. The sweet perfume from their foliage, when gently stirred by the wind, is sure to be welcome to passers-by, and the freedom with which some of the sorts bloom is quite surprising. Cuttings struck early in August and grown on gently through the winter make very nice plants by the first week in June, and by that time should be in an 8½-inch pot, and a plant from 2 feet to 3 feet high, according to the variety. Some sorts make large plants quicker than others. Some of the fast-growing sorts will make plants 6 feet high and 3 feet through in less than three years; other sorts would take six years to attain that size. They grow freely in a mixture of three parts fibrous loam, one part leaf-mould, with a little coarse sand, bone-meal, and wood ashes added. Potted moderately firm, and well looked after with water during the summer, and, given occasional weak doses of guano and soot water, they will well repay for the trouble taken. A vinery at rest is a good place to keep them during winter, when large quantities of bright flowers may be cut from them, and, cut with a portion of the foliage, they are very useful for vases and table

decoration. When the plants are taken up to house for the winter, we drop early-flowering shrubs into the holes. Grown in pots for the purpose, these make a pretty spring display, and can be lifted out again when it is safe to return the Geraniums. *Sandhurst Lodge, Berks.* W. J. TOWNSEND.

## NOTES ON HARDY PLANTS

### PERPETUAL-FLOWERING PINKS.

WE asked Mr. Ladhams of the Shirley Nurseries, near Southampton, to tell us about the perpetual-flowering Pinks, and his answer is as follows: "My new race of this charming family is the result of many years' persistent hybridising, crossing, and selecting. At one time and another almost all the different species of *Dianthus* which promised anything have been used in the work, but of course, when once the desired object was attained, these were largely discontinued. The old Mule Pinks, having strong green leaves, have had a marked effect in creating vigour and freedom of growth, forming, as it were, a groundwork for further improvements. Mrs. Sinkins as a seed-bearer also was brought in later, giving size of bloom. The race as it is at present produces stouter flower-stems, freer growth, and more refined flowers than the older border Pinks. Quite the most recent of our introductions have, in addition, purer colours. The variety Florence would rival a Carnation in its exquisite form; Marion has very large flowers on strong spikes—as many as a dozen branching buds are found on each growth; Mrs. Moulard has a chaste, beautifully-formed flower of clear pink, with chocolate centre, and has often five or six flowers out at one time on a single spike; and Ethel is of neat, graceful habit, and has full, refined, non-bursting flowers of white, delicately marked with pale purple. A few others are also in commerce, and we are selecting and eliminating amongst many other seedlings of several years' proving. In cultivation we find that plants grown on stony land enriched with decayed manure are more perennial and the colours brighter. Of course, they are at a disadvantage during excessive drought, and, as a couple of acres are grown, we

cannot pretend to water them, but they recover this as soon as rain falls or the cool nights commence, and flower more abundantly for the rest they have taken. Layering as Carnations is the only really safe way of increasing stock. Of course, they need not be lifted as Carnations are for the sake of protection, this being entirely unnecessary."

### SAXIFRAGA GRISEBACHI.

IN the course of the interesting "Notes from Worcestershire," by Mr. Arthur R. Goodwin, in *THE GARDEN* of February 13, a reference is made to this Saxifrage, and a remark made that it has succumbed to damp. I hope that no one will assume that this Saxifrage is unusually liable to damp off under ordinary circumstances. Mr. Goodwin must have been unusually unfortunate, or have experienced some untoward circumstances to account for his loss. In our corner of south-east Kirkcubrightshire we had about 50 inches of rain during 1903, and neither the end of the year nor the beginning of 1904 has shown any inclination to favour us with less rain than we had before. Under these conditions *Saxifraga Grisebachi* has done remarkably well in the open, on a rockery facing south-west, in light, sandy peat, but quite unprotected from the weather. It is still in bud, I believe, as it was when I left, but as I am from home I have not seen my plants for more than a week. Possibly Mr. Goodwin has his in a frame, where there is much more danger of such plants succumbing from damp. All through the winter *S. Grisebachi* has been very pretty, and greatly admired.

*Dumfries.*

S. ARNOTT.

### LITHOSPERMUM GRAMINIFOLIUM.

THE plant of *Lithospermum graminifolium* represented in the photograph is growing on a rockwork facing nearly south, with high Elm trees 8 yards or 10 yards off on the east side. The rockwork is steep, some 6 feet high, and a very large overhanging stone on the north side keeps off cold rain. The soil was made carefully of loam, peat, leaf-mould, and small gravel in something like equal proportions. The plant was put in not more than five years ago, and was an ordinary small nurseryman's plant. The size of the plant is nearly 3 feet long by 2 feet to 2½ feet wide. At the present time (February 12) it does not look so well as this time last year. No doubt the wet season has been very trying to it. I have a smaller plant near it that looks well and healthy. I bought the latter as intermedium, but it seems identical with the larger one, which came from the Guildford Hardy Plant Nursery.

HERBERT GREEN.

### EARLY PLANTING OF TUFTED PANSIES.

THERE is a tendency in many gardens to defer the planting of Tufted Pansies until the best time for this is past. In many gardens the Tufted Pansies are not planted until after the spring-flowering bulbs are over. As this period of the spring is not infrequently succeeded by spells of warm weather, the newly-planted tufts have little chance of getting well established before the warmer summer weather is experienced. Under such conditions it is most unreasonable to expect satisfactory results. Early planting is almost essential to success, and where this rule is seldom observed the grower has good cause for complaint.

When the weather has been suitable, and the soil also in a workable condition, I have never hesitated to plant out in their flowering quarters little tufts in February. These tufts have not been coddled in frames—a practice with the Tufted Pansy several growers now regard as quite unnecessary

LITHOSPERMUM GRAMINIFOLIUM IN A MAIDSTONE GARDEN (THE GODLANDS, TOVIR).

—but are lifted from raised propagating beds in the open, with mats of roots and numerous shoots in embryo. These plants bear the shift with comparative indifference, and even though the weather be rough or frosty immediately subsequent to the planting they come through the ordeal in excellent condition. Plants raised in cold frames, even supposing they were hardened off beforehand, are not so good for the earliest planting as are those raised in the open, as already described. The Tufted Pansies are among the hardiest of our hardy flowering plants, and after some years of careful observation I am convinced that the hardier method of raising these plants is the better one. In any case, it is better to have all planting done by the middle of March, as this practice invariably results in obtaining an early summer display, which increases as the tufts continue to develop. One hears of failure occasionally, but when this is enquired into late planting is generally responsible for it. With some of the showy French and Belgian Pansies failure invariably takes place in the later days of June and July, when the warm weather begins to test their constitution. It is to the Tufted Pansies, however, that we should look for a long, continuous, and bright display, and the sooner they are planted the better. D. B. CRANE.

### COPTIS ORIENTALIS.

THE genus to which this plant belongs is closely related to the well-known Hellebores, differing in having membranous capsules on a foot-stalk, and in the calyx falling off soon after expansion, while the members of the latter genus have leathery and sessile capsules, the sepals also remaining on till the seeds are nearly ripe. They are interesting, shade-loving little plants, requiring a moist position in peaty soil. Of modest proportions, the genus consists of only five species, all of which, with the exception of the American Gold Thread (*C. trifolia*), flower in the early spring. *C. orientalis* has much-divided, nearly evergreen leaves and white flowers on stems a few inches high. It is a native of Japan, and has been in cultivation a considerable time, and, although easy to increase by means of root division, it is rarely met with outside botanic gardens. It is never likely to be a popular plant, and only finds a place in the gardens of lovers of novelties. W. IRVING.

### AN HOUR WITH THE HOLLYHOCK.

(Continued from page 141.)

WITH the Hollyhock almost a new field for speculation and experiment lies open before us; certainly this is no bare, trodden ground, the grass is scarcely bent beneath our feet; the few alone have trampled on it. Why should we not unite in one flower the desired qualities now scattered over half a dozen? If we are seeking form and fulness, we shall find them in Beauty of Cheshunt and Honourable Mrs. Ashley. By bringing these in contact with such flowers as *Aurantia superba*, Black Prince, and Napoleon, may we not possibly raise varieties which shall combine the shape and fulness of the former with the colours or habit of the latter? If we wish to obtain flowers of any particular colour, of increased size or substance, the most probable means of so doing is to unite that colour with a flower conspicuous for those qualities.

Why should we not have the colour of Scarlet King in combination with the shape, size, and habit of Beauty of Cheshunt, or a Black Prince like *Pourpre de Tyre*? We have yet no flower of a golden yellow; none even an approach to orange. And although we do not aspire to the prevision of the prophet or seer, we venture to foretell the speedy acquirement of striped and laced flowers equal in beauty to the finest

Pink or Carnation. Then as to substance, there is room for improvement; indeed, so many points crowd upon the mind that we fear we may become chargeable with partiality in thus particularising. But as we cannot pursue this argument further we may just briefly say, that we certainly must not consider our work done until we realise in every colour the form of our ideal standard.

Let us suppose, then, that we are about to plant a seminary, and have decided that it shall contain twelve varieties; how shall we select them? The following have been chosen with the view to embrace every important feature of the flower in the greatest perfection:

- |                            |                             |
|----------------------------|-----------------------------|
| 1. Beauty of Cheshunt.*    | 7. Metropolitan.            |
| 2. Black Prince, improved. | 8. <i>Pourpre de Tyre</i> . |
| 3. Fireball.               | 9. Professor Dick.          |
| 4. Glory of Cheshunt.      | 10. Walden Rival.           |
| 5. Honourable Mrs. Ashley  | 11. White Globe.            |
| 6. Lizzy.                  | 12. Sidonia.                |

\* For the characters of these varieties, see descriptive lists.

With these materials and a camel-hair pencil we are prepared for crossing. The best time for carrying on this work is the morning, as soon as the dew passes from the flowers. There are, perhaps, no varieties, however double, which will not yield stamens and styles to a close inspection.

It is only necessary to collect the pollen from the stamens by passing the brush lightly over them and to convey it to the flower required to produce seed, drawing a muslin bag over the flower after the operation. Such kinds as are not very double and seed freely may be grown in a rich soil, and the spikes may be shortened, leaving, after thinning, about twelve flowers on each. Never allow a bad or imperfect flower to remain for seed; invariably pull off such immediately that it appears. The very double kinds may be grown in a poor soil. The spikes should not be shortened, but the flowers of all will require a plentiful thinning. As the flowers at the lower end of the stem die off the petals should be drawn from the calyx to prevent moisture from gathering round the seed-vessels, which would injure, if not destroy, the seed. Hand-picking is, perhaps, the best way of accomplishing this, and if the petals are ready to be separated they will yield to a slight pull with the finger and thumb. Crossing may be repeated day by day, as the flowers expand, until we reach the top of the stem. The plants should be watered freely during the formation of the seeds, and as the latter ripen (the shrivelling of the calyx is a tolerably correct test of fitness) they may be gathered and tied in coarse muslin bags, separately or not as the cultivator may please, and placed in a dry, airy, sunny situation. With such as flower late the spikes may be cut from the plants and placed upright in a greenhouse, or under a south wall, where the seeds will ripen better than if detached from the stem. The seeds first gathered may be sown immediately as there will be time for them to germinate and become strong before the commencement of winter. The bulk of the seed, however, cannot be sown to advantage before the spring, and early in February is perhaps the best time if flowers are required the same season. In both cases we would sow thinly in pots, placing them in a pit or house where they would command a gentle bottom-heat; and so soon as four or six leaves are formed the seedlings should be transplanted, four round a 4-inch pot. Those raised in autumn may remain in a cold frame during winter, or if in a greenhouse they should be placed close to the glass, exposed to air and light. Watch closely for slugs and remove any leaves that may decay. In April they may be transferred to the spot where intended to flower, and to do them justice they should not

be planted closer than 2 feet from row to row and 1 foot from plant to plant; they should be watered and hoed frequently during the summer, and tying up can scarcely be dispensed with. They will flower in September and October of the same year, and as any show themselves of inferior merit they should be destroyed, which will give the remaining ones more room for development. Some varieties come true from seed, or so nearly so that it would require the most practised eye to distinguish them; others come true in colour, but vary much in degree of fulness and general quality; while others again vary both in colour and quality—maroon flowers producing white, yellow, red, and the like. The seed may also be sown out of doors during any of the summer months, but the flowering will not then take place until the summer and autumn of the following year.

W. PAUL, F.L.S.

(To be continued.)

## TREES AND SHRUBS.

### HIPPOPHÆ RHAMNOIDES AS A TREE.

IN THE GARDEN for October 31 last appeared the following note with reference to the tree shown in the accompanying illustration. The leaves have now fallen, but the berries still remain, although through frost they have lost nearly all their bright yellow colour. The tree, which is quite twenty years old, was raised from seed and grown into tree form by training up a leader, and by cutting away the lower branches. The girth of the stem at 18 inches from the ground is 16½ inches. The first branches originate 4½ feet from the ground. The tree is 12½ feet through, and 15 feet high. Close by there is a tree of *H. salicifolia* nearly 30 feet high, with a girth of 49 inches. This, however, has never borne berries at Kew, although a smaller tree of the same species did so last year for the first time. The following is the note referred to:

Near the large temperate house in the Royal Gardens, Kew, there is a specimen of the Sea Buckthorn (*Hippophaë rhamnoides*) growing at the end of a shrubbery border that may rightly be termed a tree. It is of symmetrical, pyramidal shape, and from 12 feet to 15 feet high. At the present time it is as attractive as anything in the Kew collections. The pretty grey leaves alone assure the *Hippophaë* a pleasing appearance, but with the bright orange-coloured berries clustering thickly about the shoots as they do now the tree referred to makes a charming picture. Grey leaves and orange berries intermingle from top to base, for this untoward year has, curiously enough, been favourable to the Sea Buckthorn so far as the production of fruit is concerned. The stem of this Tree *Hippophaë* is about 7 inches in diameter, and the branches reach almost to the ground. As a tree it is unique. The value of *Hippophaë rhamnoides* as a bush is well known, and now its value in the garden can be fully appreciated. There are several clumps at Kew by the lakeside and elsewhere that are aglow with clusters of the brilliant orange-coloured fruits, and they make rare bits of colour in the garden landscape, more than ever appreciated now that sombre tints predominate in border and shrubbery. Because the Sea Buckthorn is a seaside plant many have the idea that it will not grow inland. Such a fallacy should at once be dispelled, and a visit to Kew would be an excellent means to

THE SEA BUCKTHORN AS A TREE IN THE ROYAL GARDENS, KEW.

this end. It does not even require to be near water at all, as is evidenced by the tree specimen just mentioned, which is growing in ordinary soil, far away from lake or pond. Berried shrubs are of great value to the gardener, and they are not taken advantage of to the extent they might be.

H. T.

**ILEX CRENATA.**

IN reference to the recent notes on this plant in THE GARDEN, I may say that this Holly is not properly appreciated in this country, probably on account of its slow growth. One use, however, which it could be put to, and for which its habit of growth admirably suits it, is in the formation of low hedges on terraces, &c., where something that is neat and compact is required. It is one of the best shrubs to transplant, and is not at all particular in the matter of soil. Given an initial dressing of manure, it will always be found able to take care of itself afterwards. Besides *I. crenata* the following evergreen species of *Ilex* are worthy of cultivation:—

*I. cornuta*.—This is a native of China, and forms a small shrub about 6 feet high and nearly as much in diameter. The leaves are about 3 inches in length, of a bright, shining green, and stiff in texture. They are each armed with seven or eight stout spines, about one-half of which point upwards and the other downwards. It is perfectly hardy, and keeps in good condition in partial shade. It bears small, dull red berries,

which are not very conspicuous.

*I. dipyrrena* (the Himalayan Holly).—This is a plant that grows to about the same size as our English Holly, which it somewhat resembles. The leaves are about the same size as those of the common Holly, but with fewer spines, and of a duller and paler colour.

*I. integra*.—This is a native of China and Japan, and is more commonly met with under the name of *Othera japonica*. It is not very hardy, but where it will succeed it is worthy of a place, as it makes a handsome evergreen. The leaves are leathery in texture, spineless, about 3 inches long, dark shining green above and lighter beneath.

*I. latifolia*.—This is of about the same degree of hardiness as the preceding, but where it will succeed it makes a distinct-looking large shrub or small tree. The leaves are from 4 inches to 6 inches in length by about 2 inches in width, rather stiff, of a dark, shining green above and lighter, almost glaucous, beneath. The edges are armed with sharp teeth. This plant keeps a better colour and grows more freely on light, dry ground than in a damper situation. The berries are small and of a dull red colour.

All these Hollies can be propagated by seeds, cuttings, or layers. In default of the first the last is the best method of increasing them.

Bagshot, Surrey.

J. CLARK.

[We draw the attention of our readers to the excellent monograph of Hollies by Mr. Bean now appearing in THE GARDEN.—ED.]

**SHADE TREES.**

(Continued from page 133.)

**TULIP TREE.**

THE Tulip Tree is too large except for the widest avenues and park borders, where there is a quantity of rich deep soil and abundance of room. It is likewise difficult to transplant, the branches are very brittle, and the leaves are continually dropping throughout the season. It is, however, practically free from enemies.

**BLACK LOCUST.**

The Black Locust is a rapid grower, hardy, easily propagated and transplanted, and does well in poor soil. It is successfully cultivated in Paris, where the top is kept small and spherical, and the branches thickly clustered. Its hard and durable wood is beginning to be used in Paris for paving the streets. On the other hand, the tree is scraggly and angular in form, its branches brittle, its foliage short-lived, its pods unsightly, and its roots badly given to sprouting. The locust-borer often kills the Black Locust, as well as the Honey Locust, and has been known to spread from these trees to certain species of Oaks.

**WILLOW.**

The Weeping Willow is the only species used on streets, and its occurrence is rare. It grows rapidly, and when perfect has a fine appearance; but the wood is tender and is often attacked by fungi, while the tussock moth and other leaf-eating insects frequently destroy its foliage. The White Willow is excellent for windbreaks and for planting along the banks of streams, railroads, and other embankments. Fine rows of this tree may be seen in Ithaca along the streams that descend from the surrounding gorges, and are subject to overflow from the melting of ice. It is also used along the Thames in the western part of London to prevent disintegration of the banks during the ebb and flow of the tide.

**TREES RECOMMENDED FOR GENERAL STREET PLANTING.**

- Oak, Red (*Quercus rubra* L.)
- „ Pin ( „ *palustris* Du Roi.)
- „ Scarlet ( „ *coccinea* Wang.)
- „ Black ( „ *velutina* Lam.)
- „ Single ( „ *imbricaria* Michx.)
- „ Willow ( „ *Phellos* L.)
- Sycamore, Oriental (*Platanus orientalis* L.)
- „ American ( „ *occidentalis* L.)

- Ailanthus (*Ailanthus glandulosa* Desf.)
- Maple, Norway (*Acer platanoides* L.)

**TREES RECOMMENDED FOR FURTHER TRIAL.**

- Ginkgo (*Ginkgo biloba* L.)
- Ash, American (*Fraxinus americana* L.)
- Hackberry (*Celtis occidentalis* L.)
- Sweet Gum (*Liquidambar styraciflua* L.)
- Kentucky Coffee Tree (*Gymnocladus dioica* (L.) Koch.)

**TREES WHOSE CULTIVATION ON THE STREETS OF LARGE CITIES IS ATTENDED WITH CONSIDERABLE RISK.\***

- Elm, American (*Ulmus americana* L.)
- Maple, Silver (*Acer saccharinum* L.)
- Horse Chestnut (*Æsculus hippocastanum* L.)
- Locust (*Gleditschia triacanthos* L.)
- Maple, Sugar (*Acer saccharinum* Marsh.)
- Linden, American (*Tilia americana* L.)
- Tulip Tree (*Liriodendron tulipifera* L.)
- Locust, Black (*Robinia pseudacacia* L.)
- Willow, Weeping (*Salix babylonica* L.)

W. A. MURRILL, in *Bulletin of Cornell University*.

**THE ROSE GARDEN.**

**NEW ROSES FOR 1903-4.**

**A** NNE MARIE SOUPERT (Hybrid Tea).—Very vigorous; fine deep green foliage; elongated bud; very large flower, with strong stalk, very full, shining red-lake colour; very free, and sweetly scented.

*Georges Laing Paul* (Hybrid Tea).—Very vigorous; elongated bud of good form; very large and full flower, with strong stem; colour a deep shining crimson-red, darker than Anne Marie Soupert; free, and very fragrant. A select variety of great value for forcing and for cut bloom. The result of a cross between Mme. Caroline Testout and Fisher Holmes.

*Olympiada* (Hybrid Tea).—Vigorous; good foliage; well-formed bud; large, full flower on long and strong stem; outer petals broad, inner ones narrower; a beautiful pink satio colour; one of the most floriferous varieties. Good for beds and forcing. (Mme. Pierre Oger × Belle Siebrecht.)

*Souvenir de Marie Zozaya* (Hybrid Tea).—Vigorous; good foliage; long bud of exquisite shape, coral-red in colour, opens freely; expanded flower of extraordinary size, full, and carried very gracefully upon a long and strong stem, Camellia shaped; the petals large and stiff, coral-red outside, silvery pink within, brighter in the centre. One of the largest of the Hybrid Teas. (Souvenir of Wootton × Belle Siebrecht.)

\* Many of these trees thrive well in villages and towns. After reading the previous discussion, several excellent trees might be selected from this list for a given locality.

*William Notting* (Hybrid Tea).—Vigorous; fine deep green leaves; elongated bud, on long and strong stem; large and full flower; outside of petals coral-red, inside salmon colour, colour in the centre resembling Mme. Abel Chatenay. A variety of quite first rank among Hybrid Teas for cutting, forcing, and grouping; fragrant and floriferous. (Abel Chatenay × Antoine Rivoire.) All the above varieties were raised by MM. Soupert and Notting, Luxembourg.

♀ *Mlle. Andrea Dourthe*.—Deep green foliage conical buds; large, full flowers of satiny pink, sometimes striped with white; under side of petals lilac; flowers continually and freely. Sport from Triomphe de la Duchère. Raised by M. J. B. Chauvry, Bordeaux.

*Mme. Victor Giraud* (Tea).—Very vigorous and free; petals white, tipped with salmon, copper-yellow towards base. Raised by M. Lapresle, Tarare (Rhône).

*Anna Jung* (Tea).—Very large, half full flower; colour bright pink, lightly shaded salmon, the centre copper coloured; elongated bud, supported by strong stalk; forms a strong bush; very free. (Marie van Houtte × General Schablikine.)

*Comtesse Emmeline de Guigné* (Tea).—Very large flower of perfect form, fragrant; large, thick petals, slightly recurving, bright carmine-red, tinted with crimson, centre copper; beautiful long bud, carmine and copper coloured; very vigorous and free. (Papa Gontier × Comtesse Festetics-Hamilton.)

*Generève Gaillardet* (Tea).—Large, half full, erect, elegant flower of bright Chinese pink colour, tinged with amber; firm petals; long, well-formed bud. (Comtesse de Lèusse × amabilis.)

*Jeanne Proudfoot* (Tea).—Large, half full flower, with thick petals; perfect form; colour pale salmon-pink; very beautiful bud. (Paul Nabonnand × Archiduc Joseph.)

*Alice Hamilton* (Bengal Rose).—Very large, half open, well-shaped flower; large petals; sweet perfume; colour bright velvety crimson-red; handsome deep green foliage. (Bengale Nabonnand × Bengal ordinary Rose.) The five preceding varieties were raised by MM. P. and C. Nabonnand, Golfe-Juan, Alpes-Maritimes.

*Mme. Alvarez del Campo* (Rugosa).—Vigorous plant, with handsome foliage and strong shoots, bearing large buds of perfect form; very big, odorous flower, flesh-pink, slightly tinted with salmon, reminding one of Pink Rover. The colour is unique among Rugosa hybrids. Fruits few but large. (Gloire de Dijon × Rugosa.)

*Mme. Lucien Villeminot* (Rugosa Hybrid).—Large, almost full flower. This plant, which is fairly vigorous, somewhat resembles Conrad Ferdinand Meyer, of which it is a product, but from which it clearly differs in the flowers, which are of a paler pink. (Conrad Ferdinand Meyer × Belle Poitevine.)

*Amélie Gravereaux* (Rugosa Hybrid).—Large, almost full flowers of deep purple-red, showing clearly the characteristics of Eugène Furst, one of the parents. This is another unique colour among

THE IRIS GARDEN AT HORIKIRI, JAPAN.

the Rugosas. (Rosa gallica × Eugène Furst × Rugosa.)

*Rose à parfum de l'Hay* (Rugosa Hybrid).—This variety, thanks to its exquisite perfume, is destined to replace in the manufacture of essence of Roses the species now cultivated for the purpose. The plant is vigorous, and easily propagated and grown. Its foliage recalls that of Rosa gallica. The flower is double, globular, slightly flattened, and of a beautiful carmine cherry-red, with the edges of the petals white. These four Rugosa hybrids were raised at l'Hay by M. Gravereaux, and are sent out by M. Cochet-Cochet, Coubert, Seine-et-Marne.

*Empereur Nicolas* (Tea).—Vigorous; very large, full flowers, bright red, always in flower. This variety, from its colour and its splendid buds, will always be a favourite for forcing.

*Dona Sol Stuart* (Tea).—Very vigorous; large, full, well-shaped white flowers, lightly tinged with yellow, passing into pure white when fully open.

*Duchesse d'Albe* (Tea).—Very vigorous; large, full, globular flowers, finely coloured, changing, according to the season, from clear red shading to carmine-pink and coppery red. Very free; a charming variety.

*Jacques Fould*.—Vigorous; large, full, well-shaped pink flowers, tinged with copper.

*Mme. Achille Fould*.—Very vigorous; very large, globular flowers, yellow, tinted with bright carmine-pink, and shaded with coppery red; sometimes altogether clear salmon-pink.

*Mme. Louis Lévêque* (Climbing Moss Rose).—The most beautiful Moss Rose yet raised; it has the size and colour of Captain Christy, and is extremely mossy; a variety of the first order; a Rose that has a great future for forcing. The six preceding varieties have been raised by MM. Lévêque et fils, Ivry-sur-Seine, near Paris.

*Mlle. Alice Rousseau* (Climbing Polyantha).—Vigorous; the bud is pink, and on opening becomes rose, tinged with carmine.

*L'Ami E. Daumont* (Climber).—Very vigorous; large, conical buds; flower scarlet-red colour, tinged with pink; the outside of the petals is purple. These two varieties have been raised by M. Rose Vilin, Grisy-Suisne, Seine-et-Marne.

*Mme. Driout* (Reine Marie Henriette panachée). This is a sport from Reine Marie Henriette, with flowers of tender pink, striped, spotted, and variegated with bright red. The plant has all the qualities of the parent; it is an excellent addition

to the list of hardy climbers. Raised by M. L. Bolut, Chaumont, Haute-Marne.

*Mme. Marie Mularin* (Tea).—Vigorous; very dwarf; medium-sized flower, always opening well, of a beautiful deep yellow, taking, especially in autumn, a violet tint; very free. A very good variety. Raised by M. Antoine Godard, Thoisy (Ain).—*Les Roses*.

#### SWEET BRIARS (HYBRID).

THESE pretty Roses are a delightful change from the usual run of varieties used for decorative arches, and their early flowering should commend them to planters who are in search of Roses of this description. Their

lusty vigour seems to demand something better than the restricted form of a bush, though in this form when isolated there is no need to restrict the growths. But given a tolerably high arch on which their shoots may be supported, the necessary bending induces a very free blossoming quite gorgeous for the short time they remain in flower. I think much could be done to make Rose arches more attractive if an autumn-flowering kind were planted with the summer-flowering variety, as unquestionably the flowerless arches are not very inviting at a time of year when one expects some bloom, even though they leave a pleasant remembrance of their early summer glory. With this object in view I would suggest that the arches be made somewhat wider than usual, although not too wide to make them appear ponderous. An intelligent use of the pruning-knife in summer, autumn, and spring will render such arches quite a feature of one's garden.

P.

#### GARDENS IN JAPAN.

BACON tells us that "God Almighty first planted a garden . . . and indeed it is the purest of all human pleasures." And he follows up this goodly opening by giving a prescription for a garden which was, apparently, to fulfil his ideal of Eden. Not less than thirty acres must be its measurement, and the lordly domain, divided geometrically into so many alleys, so many terraces, so many plots, was to be decorated with much "carpenter's work," with "broad plates of round coloured glass, gilt, for the sun to play upon," with "pyramids of green," and "over every arch a little turret with a belly, enough to receive a cage of birds."

While the courtly philosopher of the West was rejoicing in his dream of costly ugliness, the gardeners of the East had laid down one maxim for their own guidance—the garden must be its owner's world. Here is his bit of beauty's kingdom, whose every stone and shrub and rill must set him dreaming of the mountain and the forest and the sea; here, between the single Pine on the lakelet's edge and the

Maple beside the "moonshade stone" on the hillock's top lies a world of delicate suggestion, fancy's playground, an empire of romance.

The Japanese, who seems somewhat callous to publicity in the more prosaic matters of life, is jealous of the privacy of his garden. It is the place for rest of mind as well as rest of body; here he meditates, looks forward to his peaceful age, or back on the days of his youth. Here he effaces his own personality to rejoice in an opening bud, or mourn over some short-lived loveliness. All the associations of the garden must be friendly, either calm or inspiring, according to the owner's age and character. In the house many concessions may be made to the claims of material life; in the garden, thought is all; and when the Japanese thinks for beauty's sake, the result is an unerring sense of proportion in art, which constrains him to reject the most beautiful things if they are superfluous to the decoration of his home or foreign to its character.

The character or leading idea of the garden is the first thing to be considered by the landscape gardener in Japan. Here in Europe such a man would be much puzzled at receiving orders to lay out your pleasure so as to express gentleness, fidelity, hope, dignified seclusion, or self-abnegation. There is a garden attached to an abbot's palace in Tokuwamoni where the theme carried out is named "The Power of Divine Truth." To say that even in the hands of an expert these fundamental and complicated ideas could be made comprehensible to all classes of men in Japan would be untrue; they rely in great measure on national tradition, on historical, religious, and poetical associations; but the cultivated

Japanese reads them easily, and would as sharply criticise any incongruity as he would condemn any tendency to display. The avoidance of these two capital faults may be learnt by a little study of the Japanese methods. Their theory is based on Nature's own rules for her pictures; she does not give us flowers from twenty climates blooming together on an acre of ground; she does not plant the Lotus under the waterfall, or the Rice Lily on the arid hill; she leads us from grace to grace by kind degrees, and her beauties console, delight, but never tire us, because the secret of all perfection lies in gradation and harmony.

Sheets of water, small or large, constitute a feature of every garden where wealth gives the power to place them. If it be impossible to have a lake, then a tiny pond, or a rivulet, making a fall of spray, will keep the place cool and refresh the eye. So necessary, in a Japanese gardener's opinion, is the sense of space created by water that, where it cannot be had, he reminds you of it by making, at the foot of your hill perhaps, a little depression where water can lie, and filling it with small white stones that catch the light and wear an illusory gleam, like the surface of a pond. Along the edges he piles larger stones, high and rough on one side, and gently shelving on the opposite bank; then a young Pine near the stones will speak of the *Hama matsu*, the Pine of the sea. Such a device has been resorted to in Prince Horita's private garden at Yokohama, and the illusion is carried still further by the meandering stream which comes to feed the pond, intersecting the footpath of broad stones, so that a still broader flag must be laid across it as a bridge. Flat stones

are of great importance in a Japanese garden. They traverse the grass without cutting it, and, where laid in the ungrassed soil, make a good contrast to its deep brown, and give an impression of care. In large gardens their course will probably lead you to the most admired point of view or the finest group of shrubs. At the foot of a hill they will break into rocky steps, bordered on either side by hardy plants such as love the mountains. When the summit is reached, the guiding flags again appear, to bring you to the tiny rest-house or the sacred Pine. In many Japanese gardens no turf is used, and the open spaces are covered with a fine beaten earth, kept cool and dark by constant sprinkling. In the periodical deluges of rain which visit Japan, the stepping-stones are useful in the extreme. They are sometimes placed in sequences of threes or fives, then broken by an islet of small stones laid close together. Beginning as a rule near the house, and starting from the broad slab just below the verandah step (called the "removing-of-boots stone"), they curve away to the different parts of the garden, their course and sequence apparently the result of chance, in reality directed by the most minute considerations of beauty and convenience.

After the stepping-stones come the ornamental stones of the garden, of which Japanese catalogues give an immense number. Their choice must be regulated by the natural formation and character of the ground, but they are estimated as so essential that some authorities call them the framework of the garden, and rank the trees and shrubs as their accessories or supports. So the stones are put in place first, great care being taken that their size shall

A WISTARIA BOWER IN JAPAN.

not dwarf a small garden, or be swallowed up in a big one. Once in a gardener's hands they become to him the rocks and boulders of a natural landscape; the rounded masses of shrubs so constantly placed near them represent hills, and are made to roll up one behind the other to the foot of the great stones, just as the uplands roll to the base of the towering peaks and precipices of O Tome Tuge or Miogi San. The group of upright stones in the central background of Prince Horita's garden forcibly recalls a well-known point on the Miogi San, or Maiden Pass. It is difficult to be brief where so much fresh and interesting material asks to be handled; but one who knew his subject lovingly and well summed up the art of Japanese gardening in a few true words: "To let the eye, wherever it wanders, rest on something beautiful; not to ignore the smallest of Nature's works, and to seek to obtain from everything something to add to the day's delight."

## CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

### MAPLE SUGAR.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—Noticing the interesting picture of the Sugar Maple in your issue of the 23rd ult., I observe A. C. Bartlett's comment on Maple sugar, which is quite misleading. He says that "formerly the tapping of the trees in spring was an important undertaking," and that, although considered to be quite equal to cane sugar, "it but rarely found its way into commerce." Maple sugar cannot be compared with cane sugar, because its place in domestic economy is entirely distinct, but it is of commercial importance in a number of northern States and in Canada. In 1899 Vermont produced 4,779,870 lb. of Maple sugar, valued at \$64,132 dols., and 160,918 gallons of Maple syrup, worth \$134,821 dols. New York produced 3,623,540 lb. of this sugar, value 307,184 dols., and 413,159 gallons of syrup, value 323,996 dols.; Ohio, 613,990 lb. of sugar, worth 48,736 dols., and 923,519 gallons of syrup, worth 616,490 dols.; Pennsylvania, 1,429,540 lb. of sugar, worth 115,910 dols., and 160,297 gallons of syrup, worth 123,863 dols.

These represent the chief producing states, but other states supply the product in lesser volume. To the northern farmer a good "sugar bush," as the Maple grove is termed, is a valuable asset. Before the enactment of stricter pure food laws this product was much adulterated or imitated, a syrup of cane sugar often being flavoured with Maple chips and other materials, and then put up in attractive packages labelled as "Pure Vermont Maple syrup."

This syrup is not so heavy in body as ordinary molasses or treacle, but it is very sweet, not cloying, and possessed of a flavour unlike anything else. It is the only righteous accompaniment of that great American institution, the Buckwheat cake, and every "quick lunch" restaurant all over the country invariably serves a little pitcher of this syrup with every order of griddle cakes. It also blends well with any preparation of Indian meal. The sugar is mainly used in confections. In its simplest form, that of the syrup boiled down until it sugars, it is the same colour as old-fashioned brown sugar, hard and solid, moulded into little fluted cakes or large pound bricks. It is delicious, and one of the most wholesome sweets a child may eat. Enriched by other materials, the confectioners use it as a basis for many bonbons. For domestic use the sugar is often grated fine, and thus used on hot cakes like the syrup. Thus grated and stirred into whipped cream, or white of egg beaten to a froth, it is an excellent pudding sauce. It forms a basis for icings, and is used in various

cakes. A rich layer cake, with an icing of Maple sugar between the layers, masked with the same icing, and decorated with halves of walnuts, is worth trying. Maple sugar is also used in ices and other frozen desserts.

Maple sugar making begins in late winter or early spring, just as soon as sap begins to run. It ends with the departure of frost, as the sap does not sugar well or possess the right flavour when the nights begin to grow warm, and the sap then ceases to run. In many localities the work is at its highest activity while snow is on the ground. A sudden and prolonged warm spell in the height of the season means disaster to the industry. Last spring we had warm spring weather in February and March, with a killing frost in May, and sugar makers suffered heavy loss, especially in Ohio. One correspondent in Geauga County, Ohio, stated that the failure of the Maple crop was as great a calamity to his community as the failure of a trusted savings bank.

The elegant habit and stately growth of the Sugar Maple makes it a favourite shade tree here. No Maple sugar is now made in my locality, though it is produced to a limited extent in New Jersey, and was one of my juvenile diversions in a small way. Trees are tapped year after year without detriment when the work is carefully done.

EMILY TAPLIN ROYLE.

Maywood, N.J., February 4.

### WINTER PRUNING OF CURRANT BUSHES.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—If these trees are thinned out in the summer there is much less pruning to do at this season. With regard to the Black Currant none at all is required, as the pruning is much better done when the fruits are gathered. I think the trees give a much better return when the thinning out is done at the season named, as the exposure given to the fruit-buds, which are then less crowded, is beneficial. Another matter often overlooked in winter pruning is that both Red and White Currants are spurred in closely, and as the trees get old they are inclined to weaken. This can be avoided by leaving new strong shoots at the base, and, when these are large enough, the old wood may be removed. It is surprising how much better the trees bear when new wood is worked in by degrees and the older is removed. Though there must be no crowding, the new wood will give much finer bunches. Trees that have outgrown their limits and are at all weak may be much improved by reducing and working in new wood. It may take two or three years, but such trees, in addition to their appearance, well repay by the improved quality of the fruits. There must be no overcrowding at the base.

W. S. M.

## THE FRUIT GARDEN.

### STRAWBERRY FORCING—SOME WIDESPREAD ERRORS.

ONE of the most important fruit crops under glass at this time of the year is that of the Strawberry, and I should like to point out one or two errors in practice which are wide-spread and responsible for not a little of the failure to force Strawberries successfully. Two of the most important mistakes are made with the idea of saving time, or, in other words, of hastening the production of ripe fruit. It is, however, a fallacy to suppose that wrong methods will achieve that object; not only will no time be saved, but the results will be disappointing. In the first place, it is impossible successfully to force Strawberry plants into bloom before they are well rooted. If it is possible, before bringing them into the forcing house, the pots should be plunged for a few weeks in a bed of leaves made up in a pit or frame, so as to encourage root growth. Keep the frame quite cool, so as not to excite leaf-growth at all. When

the plants are well rooted they will quickly come into flower if placed in a warm house fairly near to the glass, and will bear ripe fruits, and, it goes without saying, also much finer fruits than plants brought in direct from outside. Of course, I know that it is not always possible to give Strawberry plants the careful treatment one would like to, especially where thousands are grown, but it more than repays the cultivator to get them well rooted before forcing them into flower, and any little inconvenience that this may occasion is well worth overcoming.

Another important point in connexion with Strawberry forcing is this: make quite sure that the embryo fruits are properly formed before removing the plants from the cool, airy conditions they have enjoyed while in flower to a warmer and moist house. Unless this is done deformed and stunted fruits are certain to result. Instead of swelling away quickly, as they should do when placed in a warm, moist atmosphere, they become hard, fail to develop, and mature (they do not ripen) prematurely. Some gardeners make a point of removing the plants from the house in which they have flowered as soon as the petals have fallen, taking this as a guide. It is, however, by no means an infallible one. When the petals fall the embryo fruits may or may not be formed. Until they are formed it is obviously impossible for them to develop. It is safe to say that the plants may be transferred to warmer quarters only when the numerous tiny pistils that cover the embryo fruit have shrivelled. It is these that should give the clue, not the falling petals. The petals may fall from reasons which have nothing whatever to do with the fertilisation of the blooms, such as the plant suffering from want of water, for instance. It is true, of course, that the petals of flowers do fall when the latter are fertilised, and this occurrence has probably caused many to take it as a guide. It is astonishing how quickly the small fruits will develop once they are properly "set;" the few extra days in the cool house are more than made up for by the rapid development afterwards.

A. P. H.

### WHY RESTRICT THE VINE?

WHY should we restrict the growth of the Vine when other fruit trees grown under glass are allowed to develop naturally? Take the Peach, the Fig, the Pear, the Cherry—who would think of making cordons of these and expect to secure an abundant crop of fruit and have long-lived trees? Yet why restrict the Vine to one rod, and by an annual severe pruning stunt its growth and weaken its energies? A plea for the extension or more natural growth of the Vine has on several occasions been put forward in THE GARDEN, for, as it has been pointed out, it then becomes much more healthy and vigorous, less liable to disease, and enjoys a longer life. The few remarkable examples of large Vines in this country have been referred to in support of this argument, but it is not necessary to point out such rare instances of the benefit arising from the practice of allowing the Vine to grow freely.

Take a much more common and also even a more valuable case—namely, that of the great market nurseries, from where tons of Grapes are annually sent to market. You will invariably find that the Vines are trained with two stems, and not with one, as is usually the case in private gardens, and I have no doubt that market growers would allow each Vine to have several more stems if it were not that they cannot afford to wait. They must fill their houses quickly, and therefore cannot afford to allow more than two stems to each Vine; and we may be fairly sure that the man who has his living to make from his Grapes knows how best to procure heavy crops. It is curious how the system of single-rod training should have become so widely practised throughout the country. It certainly cannot have been because heavier crops were obtained that way. If the Vines in many gardens were converted from single to double or even treble cordons, I feel sure they would give better results so far as the crop is concerned, and would thereby take a longer lease of life also.

A. P. H.

**BEGONIA MRS. H. T. DIXSON.**

WINTER-FLOWERING Begonias have been a great deal to the front lately, and they have proved most valuable plants for brightening the greenhouse and conservatory at a dull time of the year. The Begonia shown in the accompanying illustration received an award of merit from the Royal Horticultural Society on the 9th inst., when shown by Mr. H. T. Dixon, Woodside Nursery, Polegate. It is a very free-flowering variety, and is at its best during winter; for this reason it is certain to be welcome; the flowers are pink. The parents are said to be *B. Schmidtæ* alba and *Goliath*, the first named being the seed parent.

**GARDENING OF THE WEEK.**

**FLOWER GARDEN.**

**CARNATIONS.**

**P**LANTS in pots which have wintered in pits or frames should, at the first opportunity, be planted out. After making the soil firm it will be advisable to screen them for a few days with some short evergreen branches. For a large bed, Carnations associated with *Gladiolus* of the *gandavensis*, *Lemoinei*, or *nancyanus* types are very effective.

**BEGONIAS.**

If the room can be spared tubers intended for summer bedding should now be placed in boxes of soil and started in gentle heat. A suitable compost is two parts broken loam and one of leaf-mould, with plenty of sand, and a good layer of decayed manure in the bottom of the box. The tubers should be kept moderately dry until they show signs of growth. Grow the plants as cool as possible and they will be much hardier and better for planting out next June than those which are started at a later date in a forcing house. As soon as they can be handled, seedlings should be pricked off and kept growing. The *Semperflorens* section will soon require to be started on the same lines as advised for the tubers. If it is intended to increase the stock the plants may now be divided and for a short time placed in a warmer house.

**GLADIOLUS, &c.**

As weather permits the corms should be planted. If not done last autumn when storing the offsets should be rubbed off and planted closely in nursery beds; in a few seasons these will yield a good quantity of cut flowers.

*Hyacinthus* (*Galtonia*) *candicans* also require to be planted; with these it will be advisable to place the bulbs on a layer of sand. *Eucomis punctata* are too often restricted to pot culture in the greenhouse. If given liberal culture and a warm sunny position, such as at the foot of a wall, or in a border in front of the glass houses, these noble-

now until the foliage begins to ripen is the best time to feed these beautiful *Amaryllids*. The fragrant *Lycoris squamigera* is a desirable companion to the *Amaryllis*, and is amenable to the same culture. A. C. BARTLETT.

*Pencarrow Gardens, Bodmin.*

**INDOOR GARDEN.**

**CARNATION HOUSES.**

THOSE plants of tree Carnations that are in full flower would be better placed in a cool, well-aired temperature, with a little shade during the day from very hot sunshine, as the open flowers under these conditions would continue perfect for a much longer period, and, as well as being careful in the application of water to their roots, stimulants of any description should be rigidly withheld. Cuttings inserted as advised a month ago should by this time be well rooted, and, if not already done, should be potted singly into 2½-inch pots and be given a position close to the glass, and for a time a moist, close atmosphere.

**MALMAISONS.**

To the roots of those plants that are growing and producing their flower-spikes afford a little liquid stimulant, and to others, the flower-spikes of which are well advanced, give a little Clay's Fertilizer. Attend well to staking and tying up the flower-spikes, as well as to the removal of all surplus flower-buds. Carefully remove every diseased leaf. Water with the utmost care, and afford air in abundance. Fumigate occasionally.

**SMILAX**

is a plant without which scarcely any decorative arrangement is complete. Dividing the roots of established plants is a method of propagation that is frequently adopted, but plants that are raised annually from seeds sown now are perhaps the best, as they appear to possess a much freer habit of growth.

**ASPARAGUS SPRENGERI AND A. PLUMOSA**

are not difficult to raise from seeds, which sow at once, so as to afford time for the young plants to develop by the following autumn into a useful decorative size. The old plants, from which during the winter their foliage has been cut for use, should now have a portion of the old soil shaken away from the roots and afterwards be repotted into new, or in some cases top-dressing only may be necessary. It is difficult sometimes to do other than divide or split up into smaller portions those that are in baskets; but the divided parts may be placed into small-sized pots, and in this way they will form serviceable plants by the autumn. For filling baskets *Asparagus Sprengeri* and *A. deflexus* are most suitable, and when growing in this way afford them water in abundance at the roots and a well-moistened atmosphere.

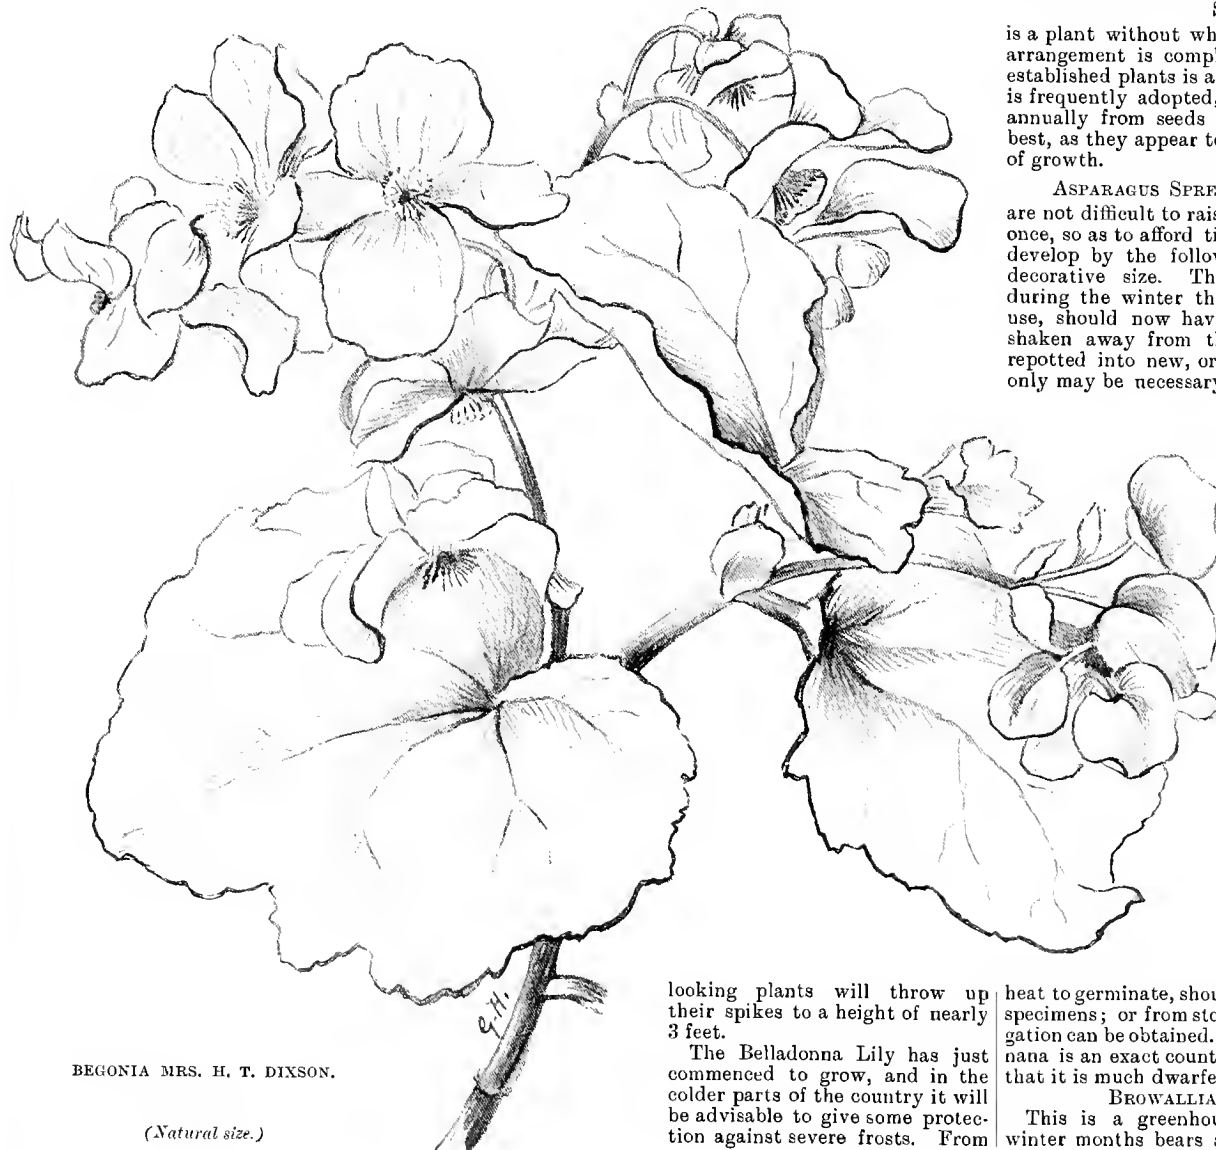

**SALVIA SPLENDENS GRANDIFLORA.**

The bright scarlet flowers of this during the autumn make a grand display in the greenhouse. It is not difficult to raise from seed, which, if sown at once and placed in a brisk

heat to germinate, should by autumn grow into good specimens; or from stock plants cuttings for propagation can be obtained. *Salvia splendens grandiflora* is an exact counterpart of the former, except that it is much dwarfer in growth.

**BROWALLIA SPECIOSA MAJOR.**

This is a greenhouse plant that during the winter months bears an abundance of large blue

BEGONIA MRS. H. T. DIXSON.

(Natural size.)

looking plants will throw up their spikes to a height of nearly 3 feet.

The *Belladonna Lily* has just commenced to grow, and in the colder parts of the country it will be advisable to give some protection against severe frosts. From

flowers. The plants when well managed can be grown to a height of 2 feet, and be formed into good specimens; but to do this sow the seeds at once, raise them in a brisk heat, and on their appearance through the soil gradually inure them to more air and light. J. P. LEADBETTER.

*Tranby Croft Gardens, Hull.*

## KITCHEN GARDEN.

### HERBS.

In most gardens an extensive collection of these are grown, and as they differ greatly in growth and hardness the present is a good time to divide, manure, and rearrange them. Vigour is increased by turning them out every third or fourth year, and giving the ground a manuring and having it well trenched. Mint may be said to be most in demand in the kitchen, and is an easy subject to manage. If this is not well fed at the root the growth gets stunted, the stems wiry, and the leaves small. Tarragon, which requires a slight protection during severe frost, may be divided now along with Chives, Thyme, and Sorrel. The herb border ought to be neatly arranged and all carefully labelled. The annual varieties ought to be sown on or near the same piece of ground. Most of them may be sown in gentle heat next month and planted out about the end of April.

### SPINACH.

Autumn-sown Spinach is now beginning to make a little growth. The prickly-seeded variety has stood the excessive wet best. A slight sprinkling of guano or reliable fertiliser should be given between the rows and hoed in. Similar treatment may be given to autumn-sown Parsley.

### GLOBE ARTICHOKE.

These will soon be starting into growth, and where it is necessary to increase the stock the plants may be divided or suckers taken from the old stools. Plant on a fairly dry border, as this plant is liable to die out if grown on wet, heavy land. The young plants should be put in rows 4 feet each way. A mulching of rough stable manure may be given now and kept on till the end of next month. This plant may also be increased by sowing seed now in heat, and if well managed will show a good supply of heads next season.

### ASPARAGUS.

Where large quantities of this vegetable are lifted annually for forcing preparations should be made now to increase the stock by seed-sowing. It is much the better plan to do this under glass than to sow out of doors. By sowing now plants may be had ready for planting about the end of May. Land for this crop should receive a liberal allowance of the best farmyard manure obtainable. This might be enriched by a good coating of seaweed, or, if the land is heavy, sea-sand. It is too early yet to remove the covering from the permanent beds. The mild weather and the entire absence of severe frosts will be certain to start this early into growth. When the protecting material has been cleared, the beds should receive a slight application of manure, salt being most beneficial. Several inches of sea-sand have also been found of great assistance. The beds should be marked off anew each spring, soil being taken from the alleys to make up the edgings. THOMAS HAY.

*Hopetoun House Gardens, N.B.*

## FRUIT GARDEN.

### HARDY FRUITS—PEACHES AND NECTARINES.

THE buds of these trees are swelling fast, and, if not already done, the pruning and nailing should not be deferred any longer. Very little pruning will be required if the trees received proper attention in disbudbing and the thinning out as advised in these columns in the autumn. The young shoots should be tied in about 6 inches apart, generally leaving them their full length. Where the trees are nailed the old shreds and nails should be removed, and burnt over a fire before using again. Use tar twine for the main branches and narrow shreds, as wide ones harbour insects later, which are difficult to remove. Where the walls

are wired care should be taken not to tie the young shoots too tightly or the trees will often canker badly.

It is a good plan to twist the ties round the wires first before tying the shoots. Syringe the trees over when finished with Quassia Extract, and this will generally carry them over the blooming period safely. Where temporary protection only is given the poles should be placed in position so that the material may be quickly fixed when required. This should be done just before the flowers open. Tanned netting is cheap, easily and quickly fixed, and can also be used later for protecting ripe fruit.

### FIG TREES.

Trees grown outside should be pruned and nailed at once, unless covered up with straw or other protection, when the work may be put off a little longer. In pruning the trees cut out any of the old wood where it can be spared, leaving the young shoots so that the trees are well furnished with bearing wood.

### STRAWBERRIES.

Old plantations of Strawberries should have a dressing of soot or charred refuse from pruning, &c., a good dressing of short stable litter being afterwards carefully placed round the plants. The rains will wash this clean before the berries ripen. Plants set out last autumn should be looked over when the ground is dry enough, as some of the plants are sure to have been lifted out of the ground by frost.

### NUTS.

The pruning of these should now be done. Remove all the suckers from the stems and any strong growths that are not well furnished. The chief object is to keep the centre of the trees open; tie down the shoots to a stake, and cut any shoots back to the required length. Old trees will be benefited by a mulching of Mushroom manure or old potting soil.

F. JORDAN.

## ORCHIDS.

### PLEIONES OR INDIAN CROCUSES.

#### AN INTERESTING WAY OF GROWING.

LOVERS of flowers who are not more or less interested in these pretty alpine Orchids are few. As is well known to many of your readers, they are natives of the lower and middle zones of the Himalaya, hence the familiar name of Indian Crocus. Nearly all the varieties cultivated in British gardens flower from October to January. They are by no means difficult to grow well, and it is not at all necessary to have a separate Orchid house for the purpose, as an ordinary plant stove or other structure with a somewhat similar temperature in the spring and summer months will do. For some years past we have grown a batch to come into flower for dinner table decoration at the annual shooting parties early in November. The kinds we have are *P. Lagenaria* and *P. maculata*, though similar treatment will answer for others. As we are about to repot or reblock our stock, a friend suggested a short time ago that he thought a few notes on our method of doing this would interest some of your readers. This was said more especially as to growing them on blocks of wood. For some years we did this on upright pieces of Elder wood, say, about 3 inches in diameter and of heights varying from 1 foot to 18 inches. We cut them level at their lower ends and stood them in shallow pans about 9 inches in diameter, these being filled with suitable soil and planted with small Ferns in some cases, and in others with *Fittonias* in variety. If preferred the two might be used together.

The object in each case is to make a natural base out of which the block seems to spring. The rooting medium for the Pleiones is made up of one-half small nodules of turfy loam, the other half being composed of tough peat and chopped sphagnum moss. Having chosen the best bulblets and also some small plants of *Episcia Cyrtodeira*, a very pretty dwarf-growing stove foliage plant, and

a few rhizomes of *Davallia bullata* (the Fern Ball *Davallia*), we began to cover up the stems. It was necessary to begin, say, from 4 inches to 6 inches from their bases, according to their height. With a small bundle of very thin copper wire a handy man will soon make up a dozen of them, which is the most we ever grew.

From ten to twelve bulblets of the Pleiones are put to each stem or block. When finished they are stood in an intermediate house, say, with a night temperature of 55°. If well watered at first very little more will be required for, say, a month, though if the weather is bright a dewing over with a syringe, using both now and hereafter tepid rain water, will be an advantage.

By the middle of March they may be stood on a side stage in a plant stove. During their whole period of active growth a good supply of water will be required. When the foliage is fully grown and the new bulblets are being formed, it is a good thing to dip each block weekly in water coloured with cow urine.

As soon as the foliage begins to decay less water will be required, but in this form of culture the rooting material should never become too dry. When the foliage falls off the blocks may be put on a stage or shelf in ainery where the Grapes are ripening. Some care will be required in timing them for flowering, as the flowers are not long lived after fully open.

During the past few years we have grown our main stock on pieces of Elder wood similar in size and character to the ones described, except that they are intended for laying on the cloth, not standing upright. In this case the under side of the block is flattened with a hatchet. They are then covered with the same mixture of soil and foliage plants worked in with, say, from twelve to fourteen bulblets on each block from 14 inches to 16 inches long. It is not necessary to have the Elder wood quite straight in this case. If bent somewhat it gives them a more natural appearance. The object in both cases is to put on the dinner table what appears to be a natural bough or branch covered with indigenous growth of a tropical or semi-tropical nature.

#### PLEIONES FOR TABLE DECORATION.

We had some for putting on the table last October that had from thirty-five to forty flowers open and opening. As a gentleman who saw them said to me at the time, "Clayton, you might have gone into an Indian forest and cut them off for the occasion." Those of your readers who have not tried this method of table decoration will find it interesting. As will be seen, it is capable of development, apart from using Pleiones. Several of the choicer scendant or semi-scendant stove foliage plants can be worked up for the purpose. I have an idea that especially the stronger of the *Anætochili* might prove of use. Why we use Elder wood is because there is plenty of it in the woods here, and its bark being of a spongy nature it holds moisture well. I have no doubt that any other rough-barked tree, say, Elm, Acacia, or Pear, would afford suitable material. Be careful not to have them too thick, or otherwise they look too dumpy, especially when used upright.

*Grimston, Tadcaster.*

H. J. CLAYTON.

## WORK FOR THE WEEK.

### CYMBIDIUMS.

THIS section of Orchids is very popular on account of their noble appearance when staged in the houses, the length of time the flowers last on the plants, or when cut for decoration they are of very easy culture and quite at home in a comparatively cold house. I recently advised beginners to grow the cool section of *Cypripediums*. *Cymbidium* would be quite at home in the same house, and would make interesting companions to the *Cypripediums*. *C. traceyanum*, *C. giganteum*, and the pleasing hybrid *C. winnianum* will now be out of flower, and should be repotted if they require it. The thick, fleshy roots like a good retentive compost. A very suitable mixture is made up of good turfy loam two parts and one part good leaf-soil, well mixed together, with a liberal sprinkling of small crocks and coarse sand; a good drainage of

large pieces of crocks should be afforded, over which place some good turfy loam to prevent the drainage becoming clogged; potting should be done rather firmly, keeping the compost below the rim of the pot. When a plant has attained large dimensions, and it is not possible to give it more pot room, break it up into pieces of more convenient size, taking every care to preserve as many roots as possible intact. In dividing a specimen loosen the roots and work away as much as is possible of the material from both sides, and then cut through the centre below the pseudo-bulbs and pull apart by hand. When the plant is thus halved it will be easier to divide to the desired size; remove any useless back bulbs, generally speaking only retain those that have leaves. The old bulbs will soon break and produce nice plants if laid on a stage and potted up when the young growth is visible.

REPOTTED PLANTS

should be carefully watered for some time, and those that have been pulled to pieces should be kept rather dry till the roots have made a start; they will benefit by frequent sprayings and damp surroundings, and should be kept well shaded from strong sunlight.

PLANTS NOW IN FLOWER.

Well-rooted plants of *C. eburneum*, *C. lowianum*, the beautiful yellow variety called *coocolor*, and *C. x Lowio-eburneum* will take a liberal supply of water; the potting of these should be deferred till after the flowering season is over and the young growths have made a fair start, when they may be treated in precisely the same way as I have advised for the winter-flowering varieties.

W. P. BOUND.

Gasston Park Gardens, Reigate.

INDOOR GARDEN.

EUPATORIUM VERNALE.

ONE of the latest novelties is this *Eupatorium*, although it has been known to science for about half a century, and those who attended the two last exhibitions at the Drill Hall could not but admire this beautiful plant. It has been cultivated in botanical gardens as *E. grandiflorum*, and under this name it has been mentioned in *THE GARDEN* as far back as January 23, 1892. In that short article it is stated that, although very little known, it is by no means inferior as a winter-flowering greenhouse plant to any of the more generally-known species. This article is also interesting, since it throws a little light upon its origin, a point about which there has been much uncertainty. It is spoken of as being hardy in the southern and central parts of France, and it resembles a plant figured in *Gartenflora*, said to have been raised from seeds found in the dust of a packing-case that had been sent full of Orchids from Guatemala. This species of *Eupatorium* may be met with under various names; it has had the misfortune to possess no less than three incorrect generic names, viz., *Ageratum*, *Conoclinium*, and *Brickellia*, but in each of these cases *grandiflorum* has been given as the specific name.

It is of shrubby habit, erect, with leaves much larger than the well-known *E. riparium*; they are rough, with serrated margin, and of a very deep colour, being of a bronzy shade, particularly when grown in a cold house or frame. The flowers, which are in large corymbs, are pure white; thus the snow-like heads produce a most pleasing contrast with the dark foliage. The flower-heads open about the second week in January, and will continue to do so through February. When in flower it is most attractive, the long and protruding styles giving it a light and beautiful appearance.

Like other *Eupatoriums*, it is a quick grower and of easy culture. Throughout the growing period it must be given plenty of moisture. During the summer months it will succeed if grown in cold frames, but it should be removed to a cold or intermediate house in September. As the plant requires a great deal of moisture at the roots a rich loamy compost will be found most suitable. It is a gross feeder, and should occasionally be given liquid manure, particularly if the plants have not been recently potted, for the roots soon fill the space allotted to them. The old plants may be cut back and repotted, and will then form quite bushes for next season's flowering. It is propagated from cuttings taken almost any time, preferably in early spring, when the young shoots are about 3 inches long. The cuttings will root readily if given a little bottom-heat and kept close in a propagating frame. Only those which are at all long need be pinched back. These grown on will form good flowering plants for next January and February.

Suckers are thrown up from the older plants, which may be removed and grown on as cuttings. It is a good plan when the plants are grown in frames to sink the pots in the ashes, and thus prevent, to a certain extent, the roots from being injured by drought. One great point in favour of *Eupatoriums* generally is that they are

and a glance over its 500 pages will show, too, that it is comprehensive. It is profusely illustrated both by photographic illustrations on art paper and by sketches interspersed throughout the text, which clearly show the methods of pruning, training, propagating, &c. The last 100 pages of the book are devoted to outline drawings (natural size) of the best Apples, Pears, Plums, Cherries, Peaches, Nectarines, Strawberries, &c., all arranged in strict alphabetical order, and therefore easy of reference. Every fruit that is worth growing in British gardens, either out of doors or under glass, is fully treated of in this work; the cultural notes come first, and then follows a list of the best varieties of the fruit under consideration. No less than 100 varieties of Apples are fully described and illustrated, and other fruits in proportion to their importance. Amateurs will find the lists of fruits for special purposes of great help.

Mr. George Bunyard treats of the cultivation of fruit trees out of doors, and Mr. Owen Thomas writes upon their culture under glass and on walls outdoors; there are additional chapters on special subjects by other experts—for instance, Mr. James Hudson (head gardener to Mr. Leopold de Rothschild) contributes a valuable article dealing with "Fruit Trees in Pots," Mr. J. J. Willis writes about "Injurious Insect Pests and Diseases," Mr. A. D. Mackenzie upon the "Construction

A HOUSE OF THE QUEEN PINE-APPLE. (From "The Fruit Garden.")

not subject to insect or fungoid pests other than red spider when allowed to suffer from want of moisture.

HERBERT COWLEY.

BOOKS.

**The Fruit Garden.**\*—In the preface to this book occurs the following sentence: "There are signs throughout the kingdom that we are slowly waking up both to the importance of fruit culture and the possibilities of its development." The truth of this must be apparent to the most casual observer, and the appearance of a practical and comprehensive work on fruit culture at the present time is most opportune. The authors' names are a guarantee that the book is practical,

\* "The Fruit Garden." By George Bunyard, V.M.H., and Owen Thomas, V.M.H. Published at the offices of *Country Life*, 6, Southampton Street, Strand, W.C.; by George Newnes, Limited; and by Charles Scribner's Sons, New York. Price 2s.

of *Fruit Houses*," Mr. W. Crump upon "Spraying Crops," Mr. S. Ponder (confectioner to her late Majesty Queen Victoria) about "Whole Fruit Preservation." Although, of course, hardy fruits and those which are generally grown under glass in this country receive most attention, there are chapters dealing with other aspects of fruit culture that are full of interest. Mr. W. Watson (curator of the Royal Gardens, Kew) is responsible for the chapter, "Tropical Fruits and How to Grow Them." This treats of fruits from the tropics, which, it is found, can be successfully grown under glass in this country, and includes the Mango, Pomegranate, Oranges and Lemons, Custard Apple, Date Plum, Banana, Passion Flower fruit, and others. Illustrations are given of most of these.

The ornamental value of fruit trees when in flower is considered in the chapter by Mr. Hugh A. Pettigrew, "Fruit Trees as Flowering Trees." The propagation of fruit trees is fully dealt with, and the various methods of grafting, budding,

HOW TO COVER A WALL QUICKLY : STANDARD AND DWARF FAN-TRAINED PEACH TREES. (From "The Fruit Garden.")

layering, &c., are clearly illustrated by means of diagrams. Root-pruning, planting, fruit storage, "The Construction of a Fruit Room," "Selections of Fruits for Various Districts" are other items of importance that are not lost sight of in "The Fruit Garden."

The profusely-illustrated chapters on "Fruit Culture in France" by M. Nombrot, "Fruit Culture in America," by Mr. H. E. Vandeman, and "Fruit Culture in the Channel Islands," by "A Channel Island Grower," afford much interesting reading. The methods practised in these countries are fully described, and, besides being valuable in themselves, may also be compared with those in vogue at home.

## NURSERY GARDENS.

MESSRS. CARTER AND CO.'S  
PRIMULAS.

WE always enjoy a visit to Messrs. Carter and Co.'s nursery at Forest Hill at Primula time, there to renew an acquaintance with favourite varieties, and also to be able to take note of new ones. For it is with Primulas as with many other flowers, new and untried varieties are constantly arising to take the place of those older sorts, which find themselves surpassed by their descendants in the all-important matters of form, colour, freedom of flowering, and vigour of growth. Some of the old-established favourites, however, are such really good flowers that even in face of the keen competition that takes place in the world of Primulas, for there the struggle for supremacy grows fiercer every year, by continued and skilful hybridisation and cross-fertilisation the newest varieties in some cases surpass their ancestors, and therefore are sought after in preference. They may, however, gain something in form or colour, yet be deficient in vigour or flowering—in fact, the great majority of newly-raised Primulas lose more than they gain (only a few prove to be real improvements), and so fail to oust the older ones altogether. Among proved Primulas of Messrs. Carter's raising are many that are favourites in gardens throughout the country, and we will first mention some of them.

Elaine is strongly represented at Forest Hill, but it seems safe to prophesy that soon it will be superseded by Elaine Improved, which is a much better variety in every way. Elaine, however, is a very good white, and still of great value for hybridising. Vermilion is hardly of vermilion colour, but is more correctly described as bright crimson. It is wonderfully free flowering, the flowers are splendidly displayed on the stalk, and a group of it makes a striking display. Holborn Scarlet is a handsome Primula, but it has one defect—namely, that the flowers fade rather quickly.

Lilac Queen is a splendid Primula. The deep lilac-rose semi-double flowers are borne in large heads and make a grand show. This variety is very free flowering, and the blooms are held well above the foliage. Ruby is a pretty Fern-leaved sort with rosy-red flowers, which are spotted with white. Holborn Pink bears large deep pink flowers, and is one of the most handsome. Magenta is a very free-flowering, brightly-coloured Primula, and Carmine is strong and free also.

King Edward VII. is a variety sent out by Messrs. Carter recently, and is undoubtedly a valuable acquisition to white Primulas. The blooms are large, white, and deeply frilled. It is a particularly strong grower. Princess May bears handsome pink blooms and is a variety that is sure to become popular. Holborn Queen, a Fern-leaf variety, continues for a long time to produce its pale blush flowers, and Hercules is remarkable for its large rose-purple blooms. Bouquet is a curious and interesting variety. The white blooms are surrounded by small green leaves, and in themselves constitute quite a miniature bouquet.

Among the double varieties are Double Scarlet, of vivid scarlet-crimson colouring; Snowflake, with blush-tinted flowers, which turn white with age; Aurora, a charming pink, and very free flowering; Prince of Wales, salmon coloured; Princess of Wales, white, with a few flakes of colour; all of which are really good varieties.

Among singles we have not yet mentioned Holborn Blue, perhaps as good as any of the so-called blue Primulas, which, however, are more correctly described as lavender blue.

Messrs. Carter have several beautiful forms among the stellata hybrids in various colours. Mont Blanc, with dark, Fern-leaf foliage and pure white, star-shaped flowers, is one of the prettiest; the white flowers and dark leaves make

a striking combination. We noticed several very pretty stellata forms whose flowers have large yellow centres. There is infinite variety in the prosecution of the culture of Primula seedlings from cross-fertilised seed, and many beautiful results are seen here. The display at Forest Hill is intensely beautiful and interesting, and shows to what perfection the Primula has been brought by careful hybridisation with a view to securing good colours.

## NOTES FROM THE MARKETS.

### COVENT GARDEN FLOWER MARKET.

**P**OT PLANTS.—The market does not fill up much yet, but there is a good supply of most seasonable subjects, and some things which are usually finished up before this are still available. Poinsettias are still on sale, but they begin to look to be past their best. Solanums are also to be seen. Erica hyemalis is almost passed, and is succeeded by E. wilmoreana. Acacias and Boronias are also to be seen. Marguerites are again very plentiful and good. Azalea indica is in various colours, but the white variety is not quite so plentiful. Azalea mollis in pretty shades of colour. Cyclamen very good on many stands. Begonia Gloire de Lorraine not over plentiful, and Daffodils of various sorts are very abundant, and many of them very good.

A few Primulas are to be seen, but they are very poor. Cinerarias are good, and the bright colours are much appreciated. Genistas are coming in plentifully. Mignonette is not yet of first quality. Lily of the Valley is not quite so plentiful in pots, but some good examples were seen in Messrs. Rochford's warehouse. They also had fine plants of Pandanus Veitchii in 6 inch pots. Hyacinths are plentiful and very good. Ferns are abundant in all the usual market sorts, except Maidenheads, but perhaps these are not much wanted just now. The Japanese Fern-balls (Davallia bullata) are very good, but little trade for them. Todea arborea, Dicksonia antarctica, Pteris Victoriae, and Asplenium lucidum are among the choicer sorts that may be seen.

*Cut flowers.*—The supply is plentiful of almost all seasonable subjects. Daffodils are the most prominent, and many of these are very fine. Emperor, Empress, Golden Spur, Sir Watkin, and Pheasant's Eye are abundant, but growers begin to complain of bad prices. Lilliums are more plentiful again. L. longiflorum is very good, also L. lancifolium. L. anratum does not make quite such fine blooms as at their natural season of flowering. Lily of the Valley is very fine and plentiful. White Azalea is plentiful, but it seems quite out of favour, and sells very slowly. Pink and white Roses are now coming in well, but there are very few good red sorts. Carnations are also beginning to get more plentiful.

*Orchid flowers* are not selling very freely. There is a good supply of Cologlyne cristata, Cypripediums, and Dendrobiums, also Cattleyas and Odontoglossums. English White Lilac, Eucharis, Gardenias, and other choice flowers are plentiful. There are also more bright-coloured flowers to be seen. The double crimson Ranunculus is very good. Anemone fulgens and the scarlet A. coronaria is plentiful, also the St. Bridg in various colours. There is still an over supply of Callas. A few good Chrysanthemums may yet be seen. The general trade is quite as good as usual for the Lenten season, and should Easter come in with fine weather we may expect to see a general revival of trade.

## THE LILIES.

(Continued from page 112.)

*L. giganteum* (Wall.).—The Great Himalayan Lily. A well-known species, apparently difficult to grow well in all soils and situations, yet thriving in quite unlikely places, so much so that we venture to think it may be grown well without elaborate preparation of soil and choice of situation. Bulbs, larger than a Cocoonut, ovoid, perennial, their lives terminating with the inflorescences, the scales formed of the thickened bases of the previous year's leaves. Stems, 6 feet to 12 feet high, green, hollow, 2 inches in diameter at the base, where they form massive roots. Leaves heart-shaped, pale green, stalked, not unlike those of a Cabbage, varying from 3 inches to 12 inches across, those from the bulbs larger and more persistent than those from the stems, those near the summit of the stems mere bracts enclosing the flower-buds, and these are woolly on the inner surface, the whole lot falling away as the flowers develop. Flowers ten to twenty in a spike, poised at right angles with the stem, or slightly drooping when expanding, each 6 inches to 10 inches long, white, the extreme base tubular, the tips reflexing or expanding fully, the funnel narrowing gradually from the tip to the base. The petals are very thick in texture, and are stained purple on the margins internally and suffused green externally. The seed-vessels are held erect. A noble Lily of imposing stature. Common in cultivation. Flowers in July and August. Inhabits the temperate regions of the great Himalayan chain, growing among shrubs mainly, but often found in forests under varied conditions, where plenty of moisture and a rich soil help its development.

**CULTURE AND USES.**—The peculiarly uncertain behaviour of this Lily under cultivation renders details of its cultivation somewhat difficult to give, and we must confine ourselves to what, in our judgment, appear to be the essential conditions. It grows naturally in the forest and is difficult to naturalise. It should be tried under various aspects, when it will soon be apparent which of these the Lily appreciates. Of essential conditions, shelter from late frosts is the more important. It requires a rich and deep soil—preferably the leaf-soil of open woods—in a fair state as regards moisture, and thoroughly to establish a plantation in the first year the smallest and the largest sized bulbs should be planted; the largest for immediate effect, the smallest to grow on and form the colony. From our observation of this Lily in various parts of Great Britain we gather that, given shelter, it may be grown in any plant border, in the wild garden, amid Bamboos and kindred plants, in the open clearings of woods, and particularly where the soil is rich and damp. Soils and situations in which Bamboos thrive would be likely to suit this Lily well. In a light soil shade is important, or the plants will grow feebly owing to drought; in heavy soils a more open exposure may be considered, but in no case would this plant thrive in a dry, wind-swept shrubbery, or, in fact, any bleak situation. We can offer no better suggestion than that this Lily should receive something of the treatment accorded to strong growing vegetables in a kitchen garden; one cannot overfeed it, the richer the soil the finer will be the spikes. Greater attention with regard to shelter will be required in late spring, when the flower-spikes are partially developed. During bulb growth the roots descend deeply, but the stem-roots, which are developed as the spikes appear, strike out in all directions, piercing the bulbs and travelling under the surface of

the soil, cart wheel fashion, several feet away. These will need a liberal mulch as they appear to preserve the growth from any check. The spike should be allowed to ripen seeds, and these should be sown at once in a place where they can be watched, and they will germinate freely in the following spring. A few offsets will survive the original bulb, hence the old stem should be cut down, not uprooted, lest the offsets be torn up with it. The bulbs may be flowered in pots, but they require bulky receptacles, and they never produce spikes so fine as those from established bulbs in the open.

G. B. MALLETT.

(To be continued.)

## THE KITCHEN GARDEN.

## CARTER'S EARLY FORCING TURNIP.

**F**EW spring vegetables are more appreciated than new Turnips, and they are soon grown. For many years the Early Paris Market and the Milan were the sorts mostly forced, but when fully matured they soon became tough and flavourless. If forced at all hard the plants failed to bulb. I am aware this is a common failing with all Turnips; they will not stand hard forcing, but, on the other hand, few give a better return when they receive attention at the start. The above-named variety is certainly well named, as it forces well, and in shape more resembles a large Radish. The long root enables it to mature rapidly, and when sown in a cold frame the early part of March I have had good roots in two months. For early borders it is equally useful, and in light soils I have found it suffer less from drought than the flatter roots. I do not advise it for storing, but to make frequent sowings, as by so doing there is a succession of sweet tender roots of excellent quality. The flesh is very white, of firm texture, and when cooked is very delicate.

## ONION BEDFORDSHIRE CHAMPION.

**S**EVERAL remarkable additions have been made of late years to Onions, the tendency in nearly all cases being to increase the size. I do not complain of this, as large, well-matured Onions are valuable, and it shows that with attention to cultural details we can grow them as well as the foreigner, and, I think, such bulbs are worth more attention as a vegetable at this season. Although Bedfordshire Champion is an old variety, it is one of the best for general use, shapely in form, and a good keeper. I have grown it for many years, and last season's crop was very good; indeed, the bulbs were large, without any special culture, and very handsome. It keeps splendidly. The bulbs should be stored thinly, or roped and suspended to a roof free of drip, but exposed well; they then keep sound into May. I prefer this variety to James' Long Keeping. The bulbs do not grow out with me so quickly, and are of a firmer texture. Of course, for keeping it is necessary to thoroughly ripen at the lifting, and in wet seasons this is difficult unless placed under glass; but it is well repaid by their long keeping, and they give a good supply of the best quality.

G. WYTHES.

## EARLY CABBAGES.

**I**n many directions complaints are made that autumn-planted Cabbages have done badly, owing to the wet weather. That is probable, as few ordinary garden vegetables can exist unless the weather be moderately favourable. Could the nature of the winter have been anticipated, it would have been a good plan to have thrown up ridges of soil 6 inches higher than the intervening spaces, each ridge being 18 inches broad, and planting two rows of Cabbages along each ridge 12 inches apart. That, with a space of 30 inches between each outside row of plants, would leave ample room for ordinary early heads to develop. The open drains between the various ridges would keep the

soil about the plants fairly dry, and enable the stems to be well earthed up. Cabbage plants often suffer greatly in windy weather, because, blown about, the stems, not being strengthened with soil, make holes which fill with water, and it is no matter for surprise if they should suffer and damp off.

A. D.

## KEW NOTES.

## INTERESTING PLANTS IN FLOWER.

*Temperate House.*

ACACIAS in variety, *Camellia reticulata*, and *Rhododendron grande*.

*Palm House.*

*Brownea coccinea*, *B. coccinea* × *B. latifolia*, *B. grandiceps*, *Clavija macrophylla*, and *Saraca indica*. *Synechanthus fibrosus* is fruiting well.

† *Range.*

*Freesia Armstrongii*, *Impatiens Oliveri*, *Mitriostigma axillaris*, and *Porphyrocoma lanceolata*.

*Orchid House.*

*Ærides Vandarum*, *Angræcum citratum*, *A. subulatum*, *Bulbophyllum neilgherrense*, *Cattleya Loddigesii*, *Cymbidium eburneum*, *C. lowianum*, *C. virens*, *Cynorchis compacta*, *Cypripedium* (various species and hybrids), *Dendrobium Ainsworthii*, *D. aureum*, *D. Berkeleyi*, *D. Cybele*, *D. endrocharis*, *D. euosium*, *D. Madonna*, *D. nobile*, *D. sarmentosum*, *D. speciosum*, *D. wardianum*, *Eria flava*, *Lælia harpophylla*, *L. lindleyana*, *L. superbiens*, *Miltonia Ruzelii alba*, *Odontoglossum angustatum*, *O. crispum*, *O. Edwardii*, *O. Insleyi*, *O. triumphans*, *Oncidium porriens*, *O. pubes*, *O. superbiens*, *Ornithidium densum*, *Phaius Blumei*, *P. Cooksoni* var., *P. Southeri*, *P. Wallichii*, *Platyclinis glumacea*, *Pleurothallis Ruzelii*, *Spiranthes plantaginea*, and *Tetramicra bicolor*.

*Succulent House.*

*Aloe ciliaris*, *A. insignis*, *Iris japonica*, and *Pitcairnia spathacea*.

*Alpine House.*

*Anemone blanda*, *Bulbocodium vernum*, *Coptis orientalis* var., *Corydalis angustifolia*, *C. kolpakowskyana*, *C. rutafolia*, *Draba Gilliesii*, *Hyacinthus azureus* var. *præcox*, *H. a. var. robustus*, *Lithospermum rosmarinifolium*, *Primula denticulata* var. *alba*, *P. megasæfolia*, *Saxifraga Albertii*, *S. apiculata*, *S. bursariana*, *S. b. var. major*, *S. Griesbachii*, *S. oppositifolia* var. *alba*, *Scilla sibirica*, *S. s. var. pallida*, and *Scoliopus Bigelovii*.

*Herbaceous Ground.*

*Adonis amurensis*, *Chionodoxa Lucilia* var. *sardensis*, *Colchicum hydrophilum*, *Crocus* (various species), and *Sarcococca hookeriana*.

*Arboretum.*

*Ericas* in variety and *Prunus davidiana*.

*Greenhouse.*

This house is particularly bright at present with a great variety of forced and ordinary greenhouse plants. The following are some of the most striking groups: *Cheiranthus kewensis* and *Paper White Narcissus*; white *Duc Van Thol* Tulips, and *Narcissi* *Empress* and *Van Sion*; *Primula sinensis* *Lady Dyke*, white, with dot plants of *Clivia miniata*, and a bronze form of *Acer palmatum*; *Eupatorium riparium*, with an undergrowth of red *Duc Van Thol* Tulips; *Cyclamen* and *Kentia sanderiana*; *Peristrophe speciosa* and *Prunus japonica* fl.-pl., with an undergrowth of *Primula sinensis* *White Perfection*; *Narcissus* *Emperor* and white *Primulas*; *Jacobinia ghesbreghtiana* and *Tulip Pottebakker*, white; double white *Primula sinensis*, *Iris reticulata*, dark blue *Hyacinthus*, *Prunus japonica* fl.-pl., and *Cheiranthus kewensis*; *Tulip Duc Van Thol*, yellow; *Lily of the Valley* and *Yucca aloifolia* var. *tricolor*; *Primula* *Giant Pink*, *P. Red Lady*, red *Hippeastrums*, and *Paper White Narcissus*; *Epacris*, *Acacias*, *Correas*, *Grevilleas*, and *Eriostemons* in variety; *Primula sinensis*, mixed varieties; red *Primulas*, white *Hyacinths*,

and white *Narcissus*. Also such things as *Coleus thyrsoideus*, *Amorphophallus Rivieri*, *Peristrophe speciosa*, *Sparmannia africana*, *Rhododendron præcox*, and *R. nobleanum*.

## OBITUARY.

### MR. JOHN MAXWELL.

**M**ANY cultivators of alpine and herbaceous plants will learn with great regret of the death of Mr. John Maxwell, Maxwelltown, Dumfries, which sad event took place on the 18th inst., after a long illness. Mr. Maxwell, who was seventy years of age, had cultivated hardy flowers for a great many years. Although the space he could devote to their cultivation was limited, no one could fail to find, at almost any time, something of interest in his garden. He was a great admirer of the *Narcissi*, and was the first in the district to have anything like a representative collection of the best varieties. It is, however, difficult to say what were his special favourites among hardy flowers. Alpines of all kinds, herbaceous and bulbous, taller hardy flowers, and hardy Ferns all claimed a share of his affections.

### MR. JOHN STOTERT BARTRUM, J.P.

WE are sorry to hear of the death at Bath lately of Mr. Bartrum, in his eighty-seventh year. He will be affectionately remembered in the city, and especially by those who loved their gardens, for he was a devoted gardener, and many years ago, when hardy flowers were despised by many, maintained a rare collection. Mr. Bartrum's work for the Royal Victoria Park and the Botanical Gardens deserves to be gratefully recalled, and he was ever willing to add to the collections there, and promote the popularity of gardening in every possible way. He greatly assisted in making the Botanical Gardens, and held the office of chairman of the committee for many years. Bath has lost a great supporter in the death of this ardent gardener.

### MR. WILLIAM COLE.

ONE of the best known horticulturists at Feltham, Mr. William Cole, of the Vineyard Nurseries, died there on the 16th inst., at the age of sixty-nine years. The death of his wife in 1902 came to him as a great shock, and affected him to a degree from which he never seemed to recover, and his health visibly declined. He took an active part in his business, as was his wont, up to Christmas last, but had been confined indoors since, keeping his bed for five days only, and undergoing great suffering borne uncomplainingly until the end came. He was buried in the Feltham Cemetery on the 22nd inst. He leaves a grown up family of four sons and two daughters, all of whom assisted him in his business in some way. For some time the business had been carried on under the title of W. Cole and Sons, and it was his expressed wish that the firm be continued. Born at Overton, Hants, on November 30, 1834, William Cole worked on a farm as a lad, where he saved a little money, and paid it to be taken into the gardens at Laverstoke, Hants; from there he went to Strathfieldsaye, Hants, under Mr. Johnson, then gardener to the Duke of Wellington, where he remained for several years; then to Chiveden, Maidenhead, under the late Mr. John Fleming; from there he returned to Strathfieldsaye, as foreman under Mr. Johnson, and on the occasion of the latter's death the Duke of Wellington wished to appoint him as head gardener, but the preference of the Duchess being for a Scotchman, Mr. Bell was appointed, the Duke making Mr. Cole a handsome present as a solace for his disappointment. Leaving Strathfieldsaye, Mr. Cole was for a time in the nurseries of Messrs. James Veitch and Sons at Chelsea, from where he was sent by the firm as head gardener at Ealing Park, then occupied by J. S. Budgett, Esq. Here he remained for some eleven years, making an excel-

lent reputation as a skilful all-round gardener, growing very fine specimen plants and excelling in Grapes. He was a leading exhibitor at the shows of the Ealing Horticultural Society and at other places in the district. In 1875 he established himself in business as a cultivator of Strawberries and Grapes for the market, growing White Muscat Grapes in particular with great success; of late years he cultivated Grapes chiefly, and up to the time of his illness took an active personal interest in the work. Mr. Cole was greatly respected both at Ealing and Feltham, and has passed away amid the regrets of a large number of attached friends. His eldest daughter has made a considerable reputation as a floral decorator, and is in the habit of taking most of the leading prizes at the exhibitions of the National Chrysanthemum Society at Richmond and elsewhere.

### MR. EDWIN JONES.

THE death is announced of Mr. Edwin Jones, senior member of the firm of Messrs. Bayliss, Jones, and Bayliss of Wolverhampton. Mr. Jones was seventy years of age.

## SOCIETIES.

### ROYAL HORTICULTURAL SOCIETY. DRILL HALL MEETING.

ON Tuesday last the Drill Hall, Westminster, was so crowded in the afternoon as to make it impossible for one to see properly the numerous beautiful displays of plants and flowers. Orchids were well shown, and hardy flowers, Primulas, forced shrubs, and indoor plants were largely exhibited also. There was only one dish of fruit shown.

#### ORCHID COMMITTEE.

Present: Harry J. Veitch, Esq. (chairman), Messrs. James O'Brien, H. Little, W. H. White, W. Boxall, F. J. Thorne, J. W. Odell, E. Hill, M. Gleeson, T. W. Bird, J. Wilson Potter, W. A. Binley, W. H. Young, F. A. Rehder, A. A. McBean, Richard G. Thwaites, H. T. Pitt, Jeremiah Colman, Francis Wellesley, James Douglas, Walter Cobb, H. Ballantine, R. Brooman White, and E. B. Crawshaw.

Messrs. Sander and Sons, St. Albans, had a splendid display of Orchids, consisting largely of fine forms of *Dendrobium wardianum*. This exhibit filled two-thirds of one side of a long table. The *Dendrobiums*, which were finely flowered, constituted the background, and miscellaneous Orchids were arranged in front. Besides many good unnamed forms of *D. wardianum*, we noticed *D. w. var. xantholeucum*, a very choice variety. Among the other Orchids were *Laelio-Cattleya blechleyensis*, *Phaius Marthae*, *Odontoglossum excelens*, *O. harrystano-crispum*, *Cymbidiums*, *Lycastes*, and *Cypripedium Clio var.*, *C. The Gem*, *C. Olympia*, *C. Transvaal*, *C. Miss Louise Fowler*, and others. Silver-gilt Flora medal.

Jeremiah Colman, Esq., Gatton Park, Reigate (gardener, Mr. W. P. Bound), exhibited some good *Dendrobiums* and *Cattleyas*. Among the former were some excellent hybrids and varieties—*D. Cybele firefly*, *D. Artemis*, *D. rubens elegans*, *D. wiganianum purpureum*, *D. Aspasia*, *D. Sybil*, *D. melanodiscus*, and *D. noble*, Pickering Lodge variety. Other interesting Orchids were *Odontoglossum hunnebellianum*, *O. Rossi majus*, *Laelia X Mrs. Gratrix*, *L. anceps waddonensis*, and *Vanda Cathcarti*. Silver-gilt Flora medal.

Sir Trevor Lawrence, Bart., Burford, Dorset (Orchid grower, Mr. White), exhibited a very choice group of Orchids, which were attractively arranged. *Sophranitis grandiflora*, made brilliant patches here and there. *Cattleya Trianae* was represented by a finely-flowered plant, and the same may be said of *Cypripedium Sallieri* hycarum, *C. Le Doux*, *C. hirsuto-Salieri*, *C. villosum*, and *C. lathamianum*. *Odontoglossum ramosissimum* bore a fine raceme of its curiously-twisted yellow flowers, with *Dendrobium signatum aureum*, with its pale yellow flowers; *Neottia picta*, with variegated leaves and brick-red flowers on erect tall racemes; *Mitostia furcata*, *Laelio-Cattleya Myra*, *Masdevallia Cheloni*, *M. hincxiana*, *Epidendrum Endresio-Wallisii*, *Ada aurantiaca*, *Odontoglossum coronarium var. minutum*, and *Epidendrum porphyreum* were all well shown. Among the *Dendrobiums* were *D. leechianum*, *D. Wigania xanthochilum*, *D. Melpomene*, and *D. Ainsworthii* Hazelbourne var. Silver-gilt Flora medal.

R. G. Thwaites, Esq., Chessington, Streatham, S.W., had a pretty display of *Dendrobiums*. The plants here an abundance of blooms, particularly *D. noble murrianum*, *D. schneiderianum*, and *D. Wigania* yellow var. Others were *D. noble* Thwaites variety, *D. melanodiscus pallens*, *D. n. Amesia*, *D. Cybele nobilium*, and *D. Andromeda*. *Laelia Gwenia* (*L. jongheana X L. Cowanii*) was shown bearing two blooms. This plant was raised from seed sown in June, 1901. Silver Flora medal.

Messrs. James Veitch and Sons, Limited, Chelsea, exhibited some pretty *Dendrobiums*; for instance, *D. Ainsworthii* var. *Elsie*, *D. Cybele elegans*, *D. Seylla*, *D. noble ballianum*, and other hybrid Orchids, among them being *Laelio-Cattleya Myra*, with rich orange sepals and petals, and crimson lip; *L. Mrs. M. Gratrix*, deep lemon-yellow; *L.-C. Orpheus*, white, with yellow-throated lip; *L.-C. Pallas*, *L.-C. warnhamensis*, *Epidendrum James O'Brien*, *Cypripedium godseffianum*, *C. Catherine* (superbly *X callosum Sanderi*), *C. Troilus* (*Sallieri X insigne Sanderi*), and *L.-C. callistoglossa*. Silver Banksian medal.

J. Bradshaw, Esq., The Grange, Southgate (gardener, Mr. G. Whitelegge), showed a small group of Orchids, among which were conspicuous *Brasso-Laelia purpurata-diglyana Mikado*, a large, handsome flower; *Lycaste Skinnerii Beauty*, *L. S. Enchantress*, *L. S. Alba*, *Cattleya Trianae* *Mavourneen*, various *Odontoglossums*, notably *O. harrystano-crispum*, *O. X Atriane*, and *O. X excelens*. Silver Banksian medal.

F. Du Cane Godman, Esq., South Lodge, Horsham, showed a finely-flowered plant of *Lycaste aromatica*, bearing two dozen blooms, which have greenish sepals and rich yellow petals. Mr. Godman also showed a plant of *Lycaste Skinnerii*, bearing some two dozen flowers. It was growing in a 6-inch pot, and was a lovely sight. He also exhibited *Platyclis glumacea* finely flowered.

M. Ch. Vuylsteke, Louchristi, Belgium, exhibited some fine forms of *Odontoglossums*, beautifully marked and spotted. Included were *O. Vuylstekei concinnum*, *O. loochristense formosum*, *O. l. Norma*, *O. V. recens*, and others.

Messrs. Hugh Low and Co., Bush Hill Park, Enfield, showed *Dendrobium crassinode*, a mass of bloom; *D. splendissimum grandiflorum*, *D. primalinum*, *Cypripedium nitens insignifium* Ball's variety, *C. Olivia* (*niveum X tonsum*), *Cattleya Trianae* (white variety), *Phalenopsis stuartiana*, and a fine form of *Lycaste Skinnerii*. Silver Banksian medal.

Messrs. Cypher and Sons, Cheltenham, had a bright display of Orchids in variety. Among them were *Dendrobium barbatulum*, a very attractive species, bearing drooping racemes of white flowers; *D. Cybele nobilior*, *D. n. nobilium*, *D. leechianum*, *D. n. statterianum*, *Laelia harridophylla*, *Masdevallia hincxiana*, M. Heathii, several *Cypripediums*, including *C. Mandie*, *C. Calypso*, and *C. Gowerii*. Silver Flora medal.

Kennedy Jones, Esq., East Finchley, gained a cultural commendation for some finely-grown and well-flowered plants of *Coelogyne cristata*.

#### NEW ORCHIDS.

*Cymbidium ballianum*.—This is a lovely flower, with waxy white sepals and petals, the throat and lip lined with yellow; it is sweetly scented. *Cymbidium eburneum* and *C. Mahonii* are the parents of this hybrid. First-class certificate.

*Cymbidium giganteum Wilsoni*.—A new *Cymbidium* from Yunnan, China, collected there by Messrs. Veitch's traveller, Mr. Wilson. It has been classed by Mr. Rolfe as a variety of *C. giganteum*. The raceme of the plant shown was short, and carried several flowers having green sepals and petals spotted with brown. The lip and throat are white, heavily marked with chocolate-red. From Messrs. James Veitch and Sons, Limited, Chelsea. Award of merit.

*Sophranitis Cattleya Sara*.—This is a pretty hybrid between *Sophranitis grandiflora* and *Cattleya Trianae*. When they open the flowers are a deep rose colour, with a shade of crimson; the lip is darker, and the throat is yellow. From Messrs. J. Veitch and Sons, Limited, Chelsea. Award of merit.

A botanical certificate was given to *Dendrobium Williamsii*.

#### FRUIT AND VEGETABLE COMMITTEE.

Present: George Bunyard, Esq. (chairman), Messrs. W. Poupart, Joseph Cheal, S. Mortimer, Edwin Beckett, George Kelt, H. Markham, J. Jaques, H. Parr, G. Reynolds, F. L. Lane, John Lyne, W. H. Divers, James H. Veitch, and Owen Thomas.

There was only one exhibit before this committee, a dish of Apples.

#### FLORAL COMMITTEE.

Present: W. Marshall, Esq. (chairman), Messrs. Charles T. Drury, R. C. Notcutt, R. Dean, John Green, William Howe, J. F. McLeod, R. Hooper Pearson, G. Reuthe, J. Jennings, C. K. Fielder, Charles Dixon, C. J. Salter, J. A. Nix, Charles Jefferies, J. W. Barr, Charles E. Pearson, R. W. Wallace, William Cuthbertson, W. P. Thomson, E. H. Jenkins, W. J. James, Charles E. Shea, and H. J. Cuthbert.

Messrs. B. S. Williams and Son, Upper Holloway, showed many fine examples of *Lilac*, *Prunus*, *Azalea mollis*, *Forsythia*, *Malus floribunda*, and other plants. Silver Banksian medal.

Mr. John Russell, Richmond, had a beautiful group, in which were *Prunus triloba*, *Azalea mollis* in many charming shades, *Andromeda speciosa*, *Gaultheria*, *Rosa latifolia* fol. var., and much more of a like character. Silver Banksian medal.

Messrs. William Cuthbert and Sons, Highgate, had a magnificent display of forced shrubs in great variety, the *Magnolias*, *Wistarias*, and *Lilacs* being especially charming and well done. To these in addition were *Laburnums*, *Spiraea confusa*, *Prunus triloba*, *Pyrus Malus Scheideckeri*, *Magnolia amabilis*, &c., with a margin and groundwork of *Aralia Sieboldii*. Silver-gilt Banksian medal.

The group from Messrs. R. and G. Cuthbert, Southgate, was an imposing display of *Azalea mollis* in great variety. Standards and bush-like were largely used, such varieties as *Alphonse Lavallée* (rose-pink with buff), *Attacairensis* (yellow), *Rudyard Kipling* (orange-yellow), and *Peter Koster* (orange-red), being very effective. Palms and other things assisted in the grouping. Silver-gilt Flora medal.

A very fine lot of *Cyclamen persicum* in white, crimson, pink, and red shades came from Mr. John May, St. Margaret's, Twickenham. The plants were excellent specimens, well grown, and freely flowered. Silver Flora medal.

From Mr. G. Reuthe, Keston, Kent, came an interesting lot of *Crocus* species, *Saxifraga Grisbachii*, *Shortia galatifolia*, *Sarracenia purpurea*, *Galax apylla*, *Iris Histrictodes major* (very fine), *I. Tauri* (very showy), *I. Danfordiae* (yellow), *Anemone blanda*, and other of the earliest flowers of the year.

A group of plants of *Begonia gigantea carminata* was shown by Messrs. J. Laing and Sons, Forest Hill. Unfortunately, the plants were hardly in flower, but the bud colouration was itself a most effective item. The plant, too, is vigorous, and possesses many points of value as a winter-flowering subject. *B. argentea guttata*, a pretty leaved sort was also in quantity.

# THE GARDEN

No. 1685.—Vol. LXV.]

[MARCH 5, 1904.

## CENTENARY OF THE ROYAL HORTICULTURAL SOCIETY.

**T**O-MORROW the Royal Horticultural Society completes its 100th year, and all interested in this great power for good in horticulture have cause for congratulation. In a short sketch of its history, contributed to the catalogue of the great May show in the Temple Gardens last year by the president, Sir Trevor Lawrence, Bart., we are reminded how deeply the love for gardening has entered into the life of the people. No truer words have been written than the following:

“The inhabitants of Great Britain have, during the last half century, and especially of late years, grown so accustomed to be surrounded by flowers, in town and country alike, that they have come to regard the present state of British horticulture as a matter of course. But no one who carries his mind back to the beginning of the last century can fail to be struck by the extraordinary progress which gardening and gardens have since made. It has often been remarked that the world advanced more rapidly during the long and happy reign of her late Majesty Queen Victoria, in all that contributes to the health, comfort, and convenience of life—that is to say, to its happiness—than during the preceding 500 years. While the Sciences generally have progressed with giant strides, horticultural science has not lagged behind. During the century but lately ended trees and shrubs, annuals and perennials, flowers and fruits, have been introduced from foreign countries in vast numbers, while the abilities of several generations of gardeners have found full scope for their exercise among a garden-loving people in improving old and raising new varieties of plants and fruits by cultivation, selection, hybridisation, and in other ways.”

Though a general history of the society should interest all who are sufficiently enthusiastic to acquire a Fellowship, there is one phase of it that perhaps appeals with greater force than its early triumphs, its years of vicissitudes, and its restoration to a proud position through a firm and wise government, and that is horticultural practice in the garden at Chiswick.

It is for this reason we have reproduced several illustrations of an historic place—the Ivy-mantled council chamber, where doubtless the treasures sent home by the society's traveller Fortune first saw the light, the famous vinery, and the old plant houses of a long distant age—all reminiscent of the intense gardening spirit of the men who in those days sent out collectors to many lands

for the enrichment of English gardens and woodlands.

The founders of the society were men of energy and foresight. The importance of horticultural practice was recognised by the establishment of a garden, and Kensington was the place chosen, with a nursery at Ealing. This was in 1818, but four years after the whole of this work was concentrated at Chiswick, where a thirty years' lease of thirty-three acres had been obtained from the Duke of Devonshire, the lease being renewed in 1852 for a like period. Many years afterwards this acreage was reduced to twelve, which are its present dimensions.

About the time the society possessed a garden of its own John Reeves was collecting in China, and he was one of the first to introduce the *Wistaria sinensis*. With what wonder, even in 1904, when new flowers flow as a steady stream into our gardens, should we view the lavender trails of so beautiful a tree! The success of Reeves was the means of the society sending out collectors at their own cost, the first of whom were Don and Forbes in 1821, and then Douglas, who explored the rich forests from North America to California. Through his courage, devotion, and knowledge our gardens were enriched by many trees which are now familiar and largely planted—*Pinus insignis*, *Abies Douglasii*, and many beautiful annual flowers.

Parkes and McRae are among the honoured names of this period; but the greatest of all is Robert Fortune, who in 1843 was sent by the society at great expense into the Far East. The yellow *Jasminum nudiflorum*, that now clouds many a garden wall with colour, was sent home by this brave traveller, who enriched our gardens with the beautiful flora of China and Japan, and revolutionised the great Tea industry in the East by transferring it from China to our Indian Empire. It is well to remember, in these commercial days, the work of Robert Fortune, and of many other collectors connected with its history.

In 1833 the Chiswick Gardens became a fashionable resort. When we read of the great exhibitions to which Society flocked in those days, but, as is the wont of Fashion, afterwards neglected, we tremble to think of the time when history may repeat itself. Financial troubles loomed ahead, and the influence of the then Duke of Devonshire, who was appointed president, was unavailing.

In those days Chiswick was a beautiful village; the residence of the Duke of Devonshire was surrounded by meadows and leafy lanes, and his interest in the society was so great that the grounds around the famous house were thrown open to visitors to the shows in the neighbouring garden, but to no purpose. The Duke died in 1858, and the Prince Consort was appointed in his place, but the sad event of 1861, at the moment when the Prince was endeavouring to place the society in a sound financial position in the newly-acquired grounds at South Kensington, was only the beginning of troubles which are fresh in the minds of some who govern the society at the present day.

Names we reverence to-day have been connected with Chiswick. George Bentham, Knight, Lindley, who suggested the holding of shows at Chiswick, and others whose labours will be recounted in the more descriptive history of the society we propose to publish. We are thankful that a society with so brilliant a beginning has maintained throughout its experimental and practical work, and, though evil days have fallen upon Chiswick, its history will be continued under more suitable conditions in the sixty acres at Wisley.

Around the garden at Chiswick cling many memories. It passes into the hands of the speculating builder, and ends its career sadly, but to most of those who have laboured there it is not forgotten even in these days of unrest and superficiality, and we close one book to open another that will, let us hope, in the years to come, record in its pages as bright a history of good work accomplished as in the long-distant past. The society is in strong hands. Its watchword is the safe one—Horticulture—and if it never swerves from that policy it will remain a power for good at home and abroad.

## TUB GARDENING.

HAVING had some years' experience with growing tender and half-hardy plants in tubs, I am complying with your request in the footnote to Mr. Paul's queries (page 160). First, as to the tubs themselves. We have used both empty paraffin casks and what are termed fusty beer barrels for many years. The prices of both are about the same, viz., 1½d. per gallon, though as we reside in a brewery district we get barrels free of railway carriage, which is an advantage. When sawing the latter in two be careful to have them cut

in the centre, which will be right across the bung-hole. A bit of half-round wood can be nailed in each half-circle, or stout zinc nailed on the outsides of them. In both cases it will be hidden with the painting that is needful. We find two coats of paint will do, though a third coat is an advantage. The two first should be lead colour, and the third green. A coat of black afterwards on the iron hoops should be given. For the smaller sizes not less than five holes bored with an inch auger should be made in the bottom of each tub. Larger ones should have more. I ought to have said that as soon as the tubs are cut in two we get some shavings or dry straw and upturn each tub over them, then set fire to them, leaving the tubs sufficiently long on fire so that the inner surface is well charred over. This is done with the object of preserving them and also destroying anything that might injure the roots of the plants when they come in contact with the sides of the tubs.

For the smaller sizes two stout box handles should be screwed on to each one. They can be purchased cheaply from any respectable ironmonger. For the larger ones stouter ones are best, say, made from bar iron  $1\frac{1}{2}$  inches in width by a quarter of an inch in thickness, each handle to be not less than 9 inches long with their upper ends turned outwards so as to take a stout 2-inch piece of wood.

The object in this case is that two persons may with the pieces of wood readily move the tubs from time to time as required. Holes should be drilled in the upright pieces of these irons to take screws for affixing them to the tubs. Any blacksmith would soon make them if required. I have been careful to go into details in this matter, feeling sure there may be many of your readers who would like to go into this very interesting form of garden decoration. Of course, those who can buy the tubs need not take the trouble to read my notes.

Whatever kind of plants are to be put into the tubs, they should, of course, be permanently planted. If proper drainage is put in and the right kind of soil there would be no need to replant for, say, three years at the least. The only exception to this rule is when, say, Chrysanthemums are grown in them. We have used tubs for this purpose for over twenty years, and find them very useful for making a good show in a large conservatory during the early winter months.

Anyone who has not a greenhouse but is in possession of a warm, dry shed from which frost can be excluded in the winter, may add much to the interest of their gardens by going in for tub gardening. The main points to be careful about in this case are to have them removed before injured by early frosts and not put completely out of doors too early in the season. If the shed has some light from windows and means of ventilation in the late spring months the following plants could be safely and well grown: Strong-growing seedling Abutilons, Agapanthus, Brugmansias, strong-growing Fuschias, Lemon-scented Verbena, Acacia lophantha, Erythrina Cristagalli, strong-growing Cannas, variegated Euonymus, and Myrtles. Care is required in each case that the soil in the tubs is not kept too wet or too dry, during the winter especially. After the first year the soil for an inch or two in depth will require to be carefully removed each spring and a little fresh put on in its place. During the height of growth a slight weekly dressing of some good artificial manure may be given.

Grimston, Tudcaster.

H. J. C.

## THE EDITOR'S TABLE.

We invite our readers to send us anything of special beauty and interest for our table, as by this means many rare and interesting plants become more widely known. We hope, too, that a short cultural note will accompany the flower so as to make a notice of it more instructive to those who may wish to grow it. We welcome anything from the garden, whether fruit, tree, shrub, Orchid, or hardy flower, and they should be addressed to The Editor, 5, Southampton Street, Strand, London.

### LENTEN HELLEBORES.

Mr. T. H. Archer-Hind, Coombefishacre, sends a charming variety of Lenten Roses, which are beautiful when seen floating in a bowlful of water. The colours are very tender and unusual, and one flower named *Devonia* is white, with a multitude of rosy purple spots, on a broad, firm petal. Tender rose, almost pure white, and many delicate shades abound in this series from Mr. Archer-Hind, who has raised so many new forms of good colours. We enjoy the flowers in a bowl, floating like Water Lilies, and in this way they keep fresh for days, especially when the stems are slit up about half their length.

### CYPRIPEDIUMS AND OTHER ORCHIDS.

A boxful of *Cypripediums* of beautiful yellow colouring come from Mr. D. M. Grimdsdale, Kent Lodge, Uxbridge. The flowers represent extremely good forms, and were gathered evidently from thoroughly well-grown plants.

### BEAUTIFUL BULBOUS IRISES.

Mr. Perry sends from his Hardy Plant Farm, Winchmore Hill, London, N., several beautiful bulbous Irises, which, we hope, all who rejoice in the early flowers of spring will have in their gardens. The hardy plant house is the place for these at this season, or a cold frame, or a window box where protection can be given during the time of flowering. In the open ground, unless in some sheltered position, the flowers get sullied by heavy rains and frosts. Mr. Perry sends *I. Heldreichii*, too well known to describe, but its purple colouring is always welcome to us; and so also is the deeper shades of *I. reticulata purpurea* and the exquisite beauty of *I. Tauri*. A very charming flower is *I. Hausnecii*; the flowers are small, of a lurid purple colour, with yellow colouring on the fall, an Iris well worth growing.

### FRUITS OF MUSA CAVENDISHII.

Mr. F. Jordan, Impney Hall Gardens, Worcestershire, sends some splendid Bananas. The bunch from which they were cut had over 250 fingers and weighed 92lb. Although Mr. Jordan says the fruits are not of such good flavour as usual, owing to the sunless season, they are far better than the best of imported ones. Mr. Jordan grows Bananas very successfully, and next week will have something to say about them in THE GARDEN.

### SALIX GRACILISTYLA MIQUEL (S. MUTABILIS OF GARDENS).

This distinct and interesting Willow has lately been sent in flower to us from Mr. Anthony Waterer's nursery at Knap Hill, Woking. It is a native of Japan, and was distributed first under the name of *S. mutabilis*. When it flowered at Kew in March, 1897, it was, however, found to be a species that had previously been described by Miquel under the name of *S. gracilistyla*. It has a graceful pendulous habit, which in the plants sent out has been rendered the more marked by their being grafted on stocks a few feet high. The leaves are oblong and pointed, and about 3 inches long by 1 inch wide; they are dark green above, paler and covered with minute silky hairs beneath. The young wood also is covered with a fine, grey, silky pubescence. Flowering in late February and early March its

leafless branches are then very pretty, thickly set as they are with short, broad catkins of a beautiful silvery grey colour. As regards the hardness of this Willow one can only say that it has withstood the last eight winters without serious injury. Whether it would survive a really severe one like that of 1894-95 has yet to be seen.

## NOTES OF THE WEEK.

### FORTHCOMING EVENTS.

March 8.—Royal Horticultural Society's Drill Hall Meeting. Horticultural Club, House Dinner at 6 p.m. Discussion opened by the Rev. Professor Henslow, on "Botanising Excursions."

March 9.—East Anglian Horticultural Club Meeting.

March 16.—Royal Botanic Society's Flower Show.

March 22.—Royal Horticultural Society's Drill Hall Meeting.

April 5.—Royal Horticultural Society's Drill Hall Meeting.

April 8.—Truro Daffodil Show (two days).

**Royal Horticultural Society.**—The next fruit and flower show of the Royal Horticultural Society will be held on Tuesday, the 8th inst., in the Drill Hall, Buckingham Gate, Westminster, at 1—5 p.m. A lecture on "Cottage and Allotment Gardens" will be given by Mr. Alexander Dean, F.R.H.S., at three o'clock. At a general meeting of the society, held on Tuesday, the 23rd ult., forty new fellows were elected, amongst them being the Marchioness of Linlithgow and the Right Hon. the Earl of Northesk, making a total of 301 elected since the beginning of the present year.

**Lectures in 1904.**—March 8, "Cottage and Allotment Gardens," by Alexander Dean; March 22, "Heridity of Acquired Characters," by Professor Henslow; April 5, "Villa Gardens," by Hugh P. C. Maule; April 19, "Diseases of the Potato," by George Masseur, V.M.H.; May 3, "Enemies of the Apple tree," by M. Charles Baltet; May 17, "The Horticultural Phase of Nature Study," by R. Hedger Wallace; June 14, "Floral Metamorphoses," by Professor Henslow; June 28, "Hybridisation of Roses," by M. Vivian Morel; July 26, "Orchid Varieties and Hybrids," by John Bidgood; August 9, as yet undecided; August 23, as yet undecided; September 6, "On Gourds," by J. W. Odell; September 20, "Methods of Employing Roses in the Decoration of Gardens," by George Gordon, V.M.H.; October 18, "Vegetable Sports," by Professor Henslow; November 1, Planting Woods for Winter Effect," by the Hon. Vicary Gibbs; November 15, "Orchard Management from a Commercial Standpoint," by Professor Craig; November 29, "On Hollies," by E. T. Cook. Till the end of June the lectures will be given at 3 p.m. in the Drill Hall, Buckingham Gate, S.W.; after June at the same hour in the Horticultural Hall, Vincent Square, Westminster.

**Notes from Baden-Baden.**—*Iris bakeriana*, although not very variable, has produced two desirable forms here; one has flowers of a deep even colour, and the other of a Prussian blue. *I. histrioides major* is an improvement on the type, all parts of the flowers being massive and broad. A charming novelty is *I. histrioides alba*; its satiny white with an orange-yellow crest attracts attention at once. As to the *Oncocycelus* Irises I have found after having experimented with a few dozen: In 1902 and the following year I left the plants alone, gave them no glass shelter last autumn, and no protection whatsoever during this season, which was cold, rainy, and sunless—in fact, I left them alone. But, to my surprise, I find that those which were just planted beneath the surface are in very good condition and thriving, whilst those which had been planted about 2 inches to 2½ inches deep are dead. It is easy to draw conclusions from this.—MAX LEICHTLIN, *Baden-Baden*.

**Northern Spy Apple.**—In this cold and damp climate Northern Spy Apple does badly; it cankers and the fruit is exceedingly dry and juiceless.—D. K., *Virginia, Ireland*.

**Nova Scotia fruit.**—The Agent-General for Nova Scotia informs us that the Crystal Palace authorities have presented a special commemorative medal to the Nova Scotia Government for the splendid exhibit of dessert, cooking, and cider Apples which have been displayed by the Fruit Growers' Association in the Canadian Court during the last three months. Nova Scotia fruit easily holds the first place among all the Apples imported into this country from abroad. By a process of systematic selection directed towards securing flavour, combined with long-keeping qualities, and by limiting production to comparatively few varieties possessing these characteristics, Nova Scotian growers have won for their fruit this enviable position. The Apple crop in Nova Scotia was unusually large last year, and over half a million barrels have already been shipped to this country.

**Fruit culture in Ontario.**—The fruit growing industry of Ontario is a very important one, with possibilities of development which should interest Englishmen who are looking for other occupations than farming and stock raising for the employment of their energies and capital. The wise solicitude of the Federal and Provincial Governments in taking upon their shoulders the investigation of and removal of various problems in the

and the fruits of the last-named split so badly before they are fully ripe. There is another variety of Bourjassotte, which is also a dark-coloured fruit, but it is not so rich as the one named above. This is called Noire. It is a more solid fruit than Grise, and not at all rich. At times these two varieties are mistaken, one being grown for the other. This was one of the best Figs in the collection at Chiswick, and it always cropped well, but it does not like hard forcing. On the other hand, it can be had very late, so that it is valuable to prolong the supply. It should not be planted out, as when given much root space it is inclined to make too much wood, but as a pot tree it is most valuable. The fruits are of a rich chocolate colour, the flesh dark red, and they are above medium size. The tree, when given good culture, crops grandly, the fruits being freely produced on the short spur growths, which this variety makes freely if closely stopped in the growing season. I class this variety as the best all-round good dark Fig for pots.—G. WYTHES.

**Precocious *Leucojum æstivum*.**—Last year I contributed a note concerning some plants of *Leucojum æstivum* that exhibited a very precocious tendency. This year, when I returned to my garden towards the end of January, after

arranged. The fungi should be lifted carefully, each with a small piece of the rotten wood to which they are attached adhering to them, and carried home. A shallow glass or china saucer or dish should be procured, and half filled with water. In this should be placed sufficient fresh green Moss almost to fill the dish, and the Pezizas can then be placed on the top of the Moss that should hide the rotten wood to which they are attached. Rough and not close-growing Moss must be used for filling the dish, that known as Fern Moss, a *Hypnum*, being the most attractive. From two to three dozen fungi, ranging in size from three-quarters of an inch to 1½ inches across, may be placed in the Moss, and these will retain their colour and freshness for a full month or more, and provide a beautiful and uncommon decoration for the living-room during the darkest days of mid-winter.—S. W. FITZHERBERT.

***Chimonanthus fragrans*.**—The chief value of the flowers of this hardy shrub lies in their fragrance and appearance in the winter. We have here a large specimen growing against a south wall; it is in full blossom, the air in the vicinity being laden with its fragrance. This plant is trained like a wall Plum tree, and the shoots are spurred in precisely the same way. The flowers are borne in January or February, when the tree is devoid of leafage. The variety *grandiflorus* has larger flowers than the type, and is altogether an improvement. The *Chimonanthus* is well adapted for culture on low walls or fences, either in the garden proper or in the pleasure grounds. The soil should be rich and open, and where such does not exist naturally means should be taken to make it so. When the tree is well established do not feed too much or over-luxuriance will result, to the detriment of free flowering. Pruning should be performed soon after the flowers have faded and before the sap commences to rise. Cut back all the previous year's growth to within four or five buds of its base. The leading shoots and those required for extension may be left intact or slightly shortened. The method of propagation usually adopted is to layer at the present time the young shoots that spring from the base of the tree.—H. T. MARTIN, *Stonleigh*.

**A new Parsnip.**—Parsnips are not favourites with all vegetable growers, but much depends upon the variety, how grown, and other details. The new variety I would call attention to is very distinct, and likely to become a more popular vegetable than the older sorts on account of its smaller size and excellent flavour. The variety in question, Sutton's Intermediate, may be classed as an intermediate form. It does not approach any of the older varieties in length, but, unless for exhibition, I fail to see the importance of this. The new Intermediate with me, sown early last May, is more like a short Carrot, but doubtless if sown earlier it would be larger or longer. I see no gain in mere size, and if sown late and the roots left in the soil and lifted as required, the quality is much improved. Of course, in heavy soils earlier sowing may be necessary, as even with Parsnips a rigid rule cannot be drawn, but there is no question as to the quality of the newer form. The flesh is very soft, there is very little core, and this variety is admirably adapted for shallow soils. The foliage is small, and the roots mature early, and in many gardens where Parsnips are in demand it would well repay the cultivator to sow an early lot in February, another two to three months later, the last being lifted as required for use. By keeping the roots thus the flavour is much better.—G. W.

**Figs St. John and Pingo de Mel in spring.**—I was pleased to read "J. J.'s" note on page 90 referring to the long season that ripe Figs may be had if there is a succession of pot trees. It would be difficult to have better quality for the late supplies. My note now concerns the earliest, and I have had St. John's ripe in February. The two early varieties noted above are not so good in quality as the black Figs. These are a greenish white, rather above middle size, and when not forced too hard the quality is excellent. The fruit is very juicy, deliciously sweet, and forcing can be done when others fail, as the St. John retains its fruit in its earlier

CARPETED WITH CROCUSES. AN EARLY SPRING PICTURE AT KEW.

interests of the farming community cannot fail to give confidence and encouragement to those who think of making Canada their home.

**Crocuses in Grass.**—It is often a matter of difficulty to cover the ground beneath large trees successfully with flowering plants, and the accompanying illustration may perhaps serve as an object-lesson. The Crocuses, now in full bloom, are growing on a grass mound beneath a large tree at Kew, and annually make a splendid display. The Crocus mound, as it has come to be called, is one of the prettiest sights at Kew in early spring. Crocuses are not everybody's favourites, but when they can be used to such advantage in a position where few plants will thrive, it is hardly necessary to say much in support of their usefulness, or, many will allow, in praise of their beauty either.

**A valuable pot Fig (*Bourjassotte Grise*).**—This was one of the four good Figs recommended in THE GARDEN (page 90) by "J. J." for pot culture, and I certainly do not think a better variety exists, taking quality as the chief consideration. Negro Largo is larger, and is by many considered the best of the black or dark-skinned fruits, but, so far as my experience goes, it is not equal to *Bourjassotte Grise*, though Nebian runs it close for quality. This is later,

an absence of about five weeks, I found that several bulbs had already flowered, most of the blossoms being then past their best. Close alongside these early-blooming bulbs a colony of bulbs that flower at the normal time is growing. These never show any sign of foliage until the leaves of the early-flowering section are fully developed. In a Torquay garden I have met with *Leucojum æstivum* in flower contemporary with *L. vernum*, but in my case these early summer Snowflakes have passed out of bloom long before there is any sign of blossom on the spring Snowflake.—S. W. FITZHERBERT.

**The Red Cup Moss.**—The pretty scarlet fungus known popularly as "red cup Moss," the botanical name of which is *Peziza coccinea*, is one of the loveliest of the "common objects" of a country walk in the winter-time. Here and there it may be found in the hedgerow, but, growing as it does on decayed wood, the most likely spot to find it in any quantity is in a damp wood or spinney. In one place, where an old plantation is never touched from year's end to year's end, it occurs annually in great numbers, the little red cups glowing on the dark ground in dozens. Few, perhaps, know what a charming and lasting indoor decoration this cup Moss will provide if artistically

stages of growth better than those of any other variety. I have bracketed the two together, as there is a strong likeness between them. Both are excellent for first supplies, and the trees when started in November will give ripe fruits in March. At the same time I should add they were considered distinct when given awards by the fruit committee some years ago, but it is not necessary to have both sorts, as they ripen together. These very early Figs have other advantages. It is surprising what a number of fruits even small pot trees will produce; indeed, they are too free, as they get overcropped at times. Unlike the Brown Turkey and some others, they are not so good for second cropping, so that they give a full crop at the start and at a season when forced fruits are very scarce.—G. WYTHES.

**Loropetalum chinense.**—A good deal of interest was occasioned by Messrs. James Veitch's excellent exhibit of this plant at the Royal Horticultural Society's meeting on the 23rd ult.; the dwarf plants bore an abundance of their curious flowers with white strap-shaped petals. Many seemed to have the idea that this is a new plant; this is, however, not the case. This *Loropetalum* was introduced in 1880, and ten years ago, on March 13, 1894, it was given a first-class certificate by the Royal Horticultural Society. Since then, however, it appears to have been rarely shown in quantity, yet this is the only way to bring any plant to the notice of the public so that they will not immediately forget its existence. The thong-like petals give the plant its generic name—loron, a thong, and petalon, a petal. It is a native of China, and belongs to the same family as the Witch Hazels. A note in *THE GARDEN* last year thus testifies to the value of this plant for flowering under glass: "One great point in its favour, apart from the beauty of the flowers, is the uncommon appearance of a well-flowered specimen, for at a little distance it seems to be veiled with clusters of white ribbon. It is much less effective as a shrub in the open ground than it is under glass."—A. P. H.

## THE AURICULA.—MARCH.

THE plants during this month will be in full growth, the flower trusses showing, and a few early varieties, if the season be mild, will be in blossom by the end of the month. Sufficient water may be given to keep the soil quite moist, but never in excess, lest the soil become sodden, which will retard rather than promote growth. Air must be given on all safe occasions. The early morning sun will benefit the plants, but in this treacherous month some trying weather may be experienced. Sunny days may be accompanied by a keen drying east wind; the plants if exposed to this will flag, and be greatly distressed. On such days some light shading material must therefore be used, and brought well over the front of the frame where air is admitted, to break the wind as well as to shade the plants, and abundance of thicker material at hand for thoroughly protecting against frost at night. Any extreme or violent alteration of temperature will prevent many pips from properly expanding, therefore every precaution must be taken to avoid this evil.

By the middle of the month many trusses will be well up, therefore attention must be directed more with the object of the development of it and the expanding of the pips than the growth of the plant. Therefore, any expedient must be resorted to to avoid violent changes of temperature, which will retard and seriously injure the delicate texture of the blooms, for after months of patient cultivation no effort must be spared to bring about the fond hopes and expectations of the patient Auricula grower. Offsets may still be removed from the parent plants, and those removed last month may have air gradually admitted,

but if they show signs of distress must be kept closed down until strong enough to take the fresh air without flagging.

*Bishop's Stortford.*

W. SMITH.

## EVERGREEN HOLLIES.

### ILEX AQUIFOLIUM AND ITS VARIETIES.

**MADERENSIS VARIEGATA.**—Like the preceding variety (*Lawsoniana*), this is marked by the large central blotch of yellow on the leaf—sometimes almost covering it—but the leaf itself is not so large, and is narrower in proportion to its length. As is the case, I think, more or less with all Hollies whose variegation is in the centre of the leaf, this has a tendency to revert to the green state.

**Marnockii.**—I believe this fine variety was sent out from the Handsworth Nurseries. It is in the way of *camelliaefolia*, many of the leaves being spineless, and having the same glossy black-green colour. Some of the leaves, however, have a few scattered spines very irregularly placed. The largest leaves are 4 inches to 5 inches long.

**Monstrosa.**—Nearly allied to *latispina*, this differs in having larger leaves, which are sometimes 4 inches long. It is also more spiny, each spine terminating a narrow triangular lobe of the leaf, which stands out half an inch from the body of the leaf. The apex is also drawn out into a long acuminate spine-tipped point. The foliage of this remarkable Holly is a deep lustrous green.

**Muntyi.**—The foliage of this variety is remarkably stiff and rigid in texture, and of a dull green. The leaf is oblong, 4 inches long by 2½ inches broad. In habit it is distinct, being a strong grower, with erect, stiff branches.

**Myrtifolia.**—As its name implies, this charming Holly has small leaves similar in size and shape to those of the Myrtle. They vary from 1 inch to 1½ inches long, and are usually toothed at the margins, but when, as occasionally happens, the margins are quite or nearly entire, the resemblance to a Myrtle is still more marked. The plant has a neat habit, and is comparatively slow growing.

**Myrtifolia aurea.**—The leaves of this variety are rather larger than in the green *myrtifolia*, and are edged with golden-yellow.

**Nigrescens.**—A large-leaved green Holly of rather striking character when well grown. The leaves are 3 inches or more long, lustrous green, and sometimes entire, sometimes spiny.

**Nobilis.**—Of the varieties with large green leaves this is one of the best. The plant has a vigorous habit, and its rich green leaves are sometimes 4 inches long and 3 inches broad. It is distinguished also by its formidable spiny teeth, which are occasionally half an inch long.

**Ovata.**—Numerous as the varieties of Holly are, it is doubtful if there is one quite so distinct from all the others as this. I have heard it suggested that it may be a hybrid between our native *Ilex Aquifolium* and the American *I. opaca*, but this seems very doubtful. It is a shrub of only moderately quick growth and somewhat close in habit. The leaves are very uniform in size, from 1½ inches to 2 inches long, and ovate; they are of a peculiarly stiff texture, and the marginal teeth are small and very regularly set. The young branches are purple, and the foliage is of a lustrous black-green. The largest plant at Kew is 18 feet high and 12 feet in diameter.

**Pendula.**—The common weeping Holly is, when well grown, one of the most effective of

lawn trees. There is a fine specimen in the Knap Hill Nursery, and some good ones also at Kew. Plants increase but slowly in height when left to themselves so pendulous are the branches, and we find it necessary to train up a few leading shoots occasionally to enable the plants to gain in height. The foliage is very much like that of the common Holly, but usually somewhat larger. The "silver" and "golden" weeping Hollies are referred to above under *argentea* and *aurea* respectively.

**Platyphylla.**—This is one of the well-known, large-leaved green varieties, notable for the deep dull green of its foliage, its robust habit, and thick-textured leaves. Its fruits are large and deep red, and the seed, whilst producing a proportion of common Holly, yet comes largely true.

**Recurva.**—A curious, small-growing Holly, remarkable for its twisted, channelled, convex leaves, the spines of which are very large in proportion to the size of the leaves, for the latter are only from 1 inch to 1½ inches long, and narrow.

**Scotica.**—The most striking character of this Holly is the almost entire absence of spines on the leaves; even the apex is usually blunt. In other respects it is a useful sort, being a good grower, and having small or medium-sized leaves of a very dark lustrous green. The leaves of *Scotica aurea* have a golden margin.

**Smithiana.**—Except that the leaves are dark glossy green without the purplish tinge of *donningtonensis*, this variety is very like the latter. The leaves are long and narrow (scarcely more than 1 inch wide), and the toothing irregular.

**Watereriana.**—A well-known and very popular Holly, and amongst the very best of the golden variegated ones. It is a well-marked variety both in habit and foliage. Being of low, compact growth, it is particularly well adapted for formal gardens, little clipping being necessary to keep it in shape. The leaf is medium-sized, usually quite free of spines, the dark green centre being edged by a band of yellow. Sometimes half or all the leaf is yellow.

**Whittingtonensis.**—Of a similar type to the previously-described *smithiana* and *donningtonensis*, this variety differs in having larger, more regularly toothing leaves than the former, and lacks the purplish tinge and very irregular toothing of the latter.

**Wilsoni.**—This is a very fine, big-leaved, green variety. The leaf is elliptical, 4 inches long by 3 inches broad, and armed with large marginal teeth. A variety bearing large red fruits.

*Kew.*

W. J. BEAN.

## THE FLOWER GARDEN.

### CLOTHING BUILDINGS WITH PLANTS.

PLANTS may be often seen clothing the walls of all descriptions of houses, &c., from the castle to the cottage. By their use a dull or even ugly house may be made presentable, but the selection must be made according to the building. Plants that are suitable for clothing the walls of buildings are fairly numerous, so that adequate choice may be made to meet any case, and varied tastes can be gratified. If flowering climbers are preferred, a selection may be made from the following: *Ceanothus*, in something like a dozen kinds, including the remarkably beautiful, though, unfortunately, somewhat tender, *C. veitchianus*, which should be given protection during severe weather. The *Clematis*, again, may be had in great variety, both in hybrids and species, of which

*C. montana*, that produces an early and dense profusion of small white blossoms, should not be overlooked, though most of the garden hybrids are much more showy. Those of the Jackmauni section are particularly hardy. Amongst the big family of Passion Flowers *P. cœrulea* and *P. c. Constance Elliott* are quite hardy, and the latter, especially when furnished with its lovely white blossoms, is very charming. Of *Wistarias* *W. sinensis* is the best climber, and, once it becomes well established, it yields during May and June graceful clusters of beautiful mauve flowers in abundance, but owing to its strong growth it should be given ample space. The finest of all flowering plants for a suitable building, however, is *Magnolia grandiflora*, and of this the Exmouth variety is the freest. Its magnificent and powerfully scented flowers and fine foliage are fairly familiar. This *Magnolia* is not perfectly frost proof, and requires protection in severe winters. Amongst other free-flowering hardy shrubs that are more or less adapted for planting against walls the following deserve notice: *Escalonia*, *Pyrus*, and *Lonicera* (Honeysuckle) in variety; *Forsythia suspensa*, &c.; *Jasminum nudiflorum*, *J. officinale*, and *J. revolutum*; *Fuchsia Riccartoni*. One of the most charming sights of the kind that I have seen was the front of a cottage covered with this graceful hardy plant in blossom. Other desirable, though somewhat tender, plants belonging to this division are *Choisya ternata*, *Chimonanthus fragrans*, *Garrya elliptica*, *Pittosporum Tobira*, and the hardiest *Camellias*. The latter succeed well in Cornwall and similar favourable climates, while the lovely new *Carpenteria californica* should be given a trial.

Ornamental berried plants are represented by *Cratægus Pyracantha crenulata* and *C. Lelandi*, which succeed splendidly upon northern aspects, and *Cotoneaster microphylla*, *C. Simonsii*, &c. Then amongst plants of neat growth there are *Azara microphylla*, the inconspicuous blooms of which have a distinct vanilla scent, the Myrtles, *Pomegranates*, &c. For affording a display of elegant foliage during the summer and autumn months, there are some valuable deciduous climbers, including *Vitis Thunbergii*, *V. Coignetæ*, *V. flexuosa*, *V. f. major*, &c., *Ampelopsis Veitchii*, *A. hederacea*, *A. h. muralis*, &c. The leafless winter condition of these otherwise effective plants is, however, certainly a drawback to them. The Ivy, which is undoubtedly one of the most hardy and generally useful of all wall-clothing plants, must not be omitted. There are many varieties,

THE IVY-COVERED COUNCIL HOUSE AT CHISWICK.

including beautiful golden and silver variegated forms, which, together with choice green varieties, are too numerous to particularise here.

Then these notes would be very imperfect without reference to the Rose, the most desirable of all plants, when properly selected, for planting against suitable walls. The most useful varieties for this purpose are to be generally found amongst *Teas* and *Noisettes*, and such kinds as the following are very useful: *Alister Stella Gray*, *W. A. Richardson*, *Maréchal Niel*, *Celine Forestier*, *Rêve d'Or*, *Mme. Alfred Carrière*, *Reine Olga de Wurtemberg*, *Reine Marie Henriette*, climbing *Niphetos*, *Gloire de Dijon*, *Mme. Berard*, *Belle Lyonnaise*, *Longworth Rambler*, &c.

T. COOMBER.

#### DAHLIA PLANTING PREPARATIONS.

THE best of advice given to Dahlia cultivators, and especially to those who grow for exhibition

purposes, is to prepare their ground for planting in good time. A deep trenching before Christmas, or as soon after that season as possible, is highly desirable. It is then best able to assimilate all those fertilising and ameliorating influences bounteous Nature bestows on the soil. It is simply necessary to trench the ground; no manure needs to be mixed with the soil at the time; then it may remain until planting time. I am, of course, presuming that a plantation of the leading varieties of Dahlias is grown for exhibition purposes. In the interim there is the growing on of the plants, so as to have them as vigorous in growth and as well rooted as possible. The first and second weeks in June are early enough to plant out with safety. The ground to be planted should be marked out and the positions of the plants determined; they should be from 5 feet to 6 feet apart each way, so as to admit of a free passage of the cultivator among them. At planting three or four spadefuls

of earth are taken out of the hole, and pretty well the same quantity of well rotted manure placed in it, and well mixed with the remaining earth in the hole. Some fine soil should be ready to hand at the time to place about the roots of the young plants and a stake for the support of the main stem. Amateur growers of the Dahlia who may order young green plants and receive them early in May should keep them close for two days if they have been closely packed for transit, then replot them, and be careful to keep them growing into sturdy plants, repotting once more if necessary.

R. D.

#### HABROTHAMNUS (CESTRUMS) IN THE FLOWER GARDEN.

HABROTHAMNUS are seldom seen outside the greenhouse or conservatory, yet when grown into specimen plants from 6 feet to 8 feet high they make lovely plants for grouping in the flower garden in summer. Grown in fairly large pots, and plunged to the rim in the turf in a group on the lawn, they bloom freely till very late in the summer, and when frost is likely to set in they can be removed to the conservatory, where they will still bloom very freely till after Christmas. Three very free-flowering useful kinds which group well together are *Habrothamnus Newelli*, *H. aurantiacus*, and *H. Smithii*. These will make a lovely group

THE FAMOUS VINERY, ONCE A SHOW HOUSE. (Length 150 feet, width 30 feet, height 26 feet.)

INTERIOR OF ONE OF THE OLD CHISWICK VINERIES.

that will throw quantities of excellent flowers, which are much finer than when under glass. The plants grow freely in good fibrous loam and leaf-mould. During the summer they should be top-dressed at intervals of about three weeks, with a mixture of loam, wood ashes, and bone-meal, and watered about twice a week with weak guano and soot water.

Sandhurst Lodge, Berks.

## THE LILIES.

(Continued from page 157.)

**LILIIUM GRAYI** (S. Wats.), Asa Gray's Bell-flowered Lily.—A very pretty species from the Alleghanies of Virginia and North Carolina; it is closely allied to *L. canadense*, but differs considerably in its roots and the shape of its flowers. Bulbs annual, the new growths being thrust 3 inches to 4 inches distant by a stout ivory-white stolon; the scales numerous, very stout, white. Stems slender, hollow, rooting but sparsely below, 3 feet to 4 feet high. Leaves in four to five whorls, a few scattered above, narrowly lance-shaped, thin in texture, scarcely at all recurving. Flowers borne in a

grow than its close ally *L. canadense*, as it requires much less moisture and shade. Its bulbs are larger and stronger, and its rooting powers altogether greater. The situations and uses advised for *L. canadense* will suit this plant also, but the drier conditions are more beneficial, and it may be also usefully employed in the well-tilled plant border. One can flower the plant well in pots, but it soon perishes when thus treated.

*L. Hansonii* (Leicht.), Hanson's Orange Martagon Lily.—A very beautiful Japanese species, that proves exceptionally easy to grow in all soils and situations provided it is not frozen whilst in growth. Bulbs white, conical or globose, larger than a hen's egg. Stems bright green, 3 feet to 5 feet high, rooting from the bases under good cultivation, nodding at the top. Leaves whorled below, scattered above, bright green, flaccid, 6 inches long below, smaller above, lance-shaped. Flowers six to ten in a nodding raceme, closely arranged, the buds heavy and markedly channelled. The petals are acutely triangular, very stout, and they do not reflex to the extent of Martagon. Colour a rich golden orange, spotted purple below. Each flower is 3 inches to 4 inches across, and lasts a long time in good condition. Common in cultivation. Flowers in June.

**CULTURE AND USES.**—This is one of the best garden Lilies, succeeding in all manner of soils, provided they are well tilled. It likes a warm and sheltered situation. Its early growth, and the fact that the buds are visible in a young state, render protection from late frosts absolutely necessary. The bulbs should be planted in late autumn in order that they may re-establish themselves before winter, and it should be noted that the feeding roots are at the base, hence the soil beneath them

drooping umbel of eight to ten on long nodding foot-stalks, colour reddish crimson, densely spotted internally with maroon-black from the tips to the base. They are bell-shaped, 2 inches across and 3 inches long, and the tips do not reflex as in *canadense*, and the large chocolate-coloured anthers fill up the tube. A neat, pretty species, rather sombre in colour compared with *canadense*, but a much better plant to grow. Common in cultivation. Flowers in July.

**CULTURE AND USES.**—This dainty

Lily proves easier to

should be well worked and enriched; the roots from the stems are naturally feeble, though capable of being developed to a useful extent by liberal surface cultivation. In light soils the bulbs tend to split up into countless offsets, incapable of flowering well unless helped to develop fully. This Lily grows magnificently in pots, and we have found it more satisfactory to use large pots that would hold four to six bulbs each, thus forming a good specimen. The bulbs need not be buried so deeply as is usual with stem-rooting kinds, as their basal roots need space for development.

G. B. MALLETT.

## THE ROCK GARDEN.

A CORNISH ROCK GARDEN.

**M**ID-FEBRUARY is not the time that one would voluntarily choose for visiting a rock garden, but, though at that season of the year there is but little blossom to be seen, the plants are there, and, looking forward with the eye of faith, one can realise the effect they will produce when brighter suns and warmer weather shall have enabled them to attain the zenith of their display. I therefore welcomed the opportunity of renewing my acquaintance, even at such an early period of the year, with a rock garden constructed rather less than three years ago, and of which I expect great things in the future. The ground which it occupies is perfectly flat, and thus does not lend itself naturally to the formation of a rock garden, but, as it has been raised in places, and constructed with many rock masses of large size and smaller fragments judiciously arranged, sites where the plants may enjoy the fullest sunshine or complete shade, with alternations between the two extremes, have been abundantly provided. It occupies a considerable extent of ground, and already contains a very large selection of rock and other plants, all of which are apparently enjoying the best of health, though, as the garden is of recent construction, they have not, up to the present, as completely furnished it as they will have in the course of a few seasons. The grit of disintegrated rock is largely used in planting with the best results, and seeds sown in this without any admixture of soil are found to produce strong and healthy plants.

To enumerate all the plants to be found in this garden would fill some columns, so I will confine my remarks to a few of the most interesting. Of Saxifrages there was a large collection; *S. Boydii*, generally considered a difficult plant to grow, was in splendid health, as was *S. burseriana* major. *S. oppositifolia*, *S. juniperina*, and *S. retusa*, which also sometimes give trouble, had made fine patches, and were evidently contented with their sites and surroundings. A good plant of *S. Griesbachii* was in flower, the crimson flower-heads and stalks showing up conspicuously from their background of silvery rosettes. *S. pyramidalis*, *S. longifolia*, *S. Cotyledon*, and *S. lantoscana* were represented by many fine specimens, and *S. Wallacei*, *S. Rhæa*, and *S. Rhæa superba*, of which there were several plants, were excellent. *S. valdensis* showed large bosses of tiny silvery rosettes, and of other Saxifrages I saw *S. sancta*, *S. apiculata*, *S. calyciflora*, *S. guthriana*, *S. muscosa*, *S. m. purpurea*, and *S. macnabiana*, while the annual *S. Cymbalaria* had seeded itself freely everywhere, to be uprooted where it interfered with any more valuable neighbour. Of Sedums and Sempervivums there were large and representative collections, and many Opuntias and Aloes were also in good health, as was a *Dasylyrium* that had been out unprotected for two winters. Amongst other plants were included *Alsine Rosani*, several *Androsaces*, all of which had done well, many species of dwarf *Campanulas*, *Caragana aurantiaca*, a fine clump of *Celnisia Munroi* in an elevated position, which flowered well last year and was in robust health, the bulbous *Clidanthus fragrans*, several of the *Dianthus* family, of which

AN OLD-FASHIONED ENGLISH PLANT HOUSE AT CHISWICK.

*D. alpinus* was in an especially flourishing condition, *Dryas Drummondii* and *D. octopetala*, both forming spreading mats of foliage, *Edrianthus* (*Wahlenbergia*) *tenuifolius*, *Frankenia laevis*, *Genista humifuga* amongst several of the dwarf Brooms, *Gutierrezia Euthamiae*, *Helianthemum lunulatum* and *H. Tuberaria*, a large patch of *Houstonia serpyllifolia*, *Hymenanthus crassifolia*, a breadth of that charming little annual *Ionopsidium acaule* in full flower, *Linum monogynum* and *L. alpinum album*, *Margyricarpus setosus*, *Melaleuca ericoides*, *Nepeta Mussini*, *Nierembergia filicaulis*, *Ostrowskia magnifica* throwing up strongly, the Shamrock Pea, *Parochetus communis*, which had spread over a large patch of ground, *Parrya Menziesii*, *Pourettia mexicana*, many *Primulas*, of which a colony of *P. scotica* nestling beneath a large overhanging rock was showing signs of vigorous growth, *P. megasefolia* in flower, and a healthy patch of *P. frondosa*.

*Ramondias*, *Shortia galacifolia*, and *Silenes* of sorts were abundant, and beneath a rocky ledge *Soldanella alpina* was blossoming. *Spigelia marilandica*, *Teucrium pyrenaicum*, and *Wulfenia amherstiana* were represented by good examples, and of dwarf *Veronicas*, *V. anomala*, *V. pectinata rosea*, the little shrubby *V. Hectori*, *V. loganioides*, and *V. cupressoides* were noticeable. Alpine *Rhododendrons* were in full bud, *Azalea procumbens* covered a flat rock with its trailing stems, and the dwarf Willow *Salix serpyllifolia* showed its prostrate growth. *Cotoneaster congesta* spread over a rocky mound, and on another the curious and rarely-seen *Rubus australis* was making strong growth. This will have to be severely kept within bounds if it is not to become a nuisance, for an unpruned example in the south-west has completely smothered neighbouring evergreen shrubs, and has even invaded the branches of an adjacent Fir tree. In Grasses and Rushes, of which many species were present, the Corkscrew Rush, *Juncus spiralis*, the maroon-leaved *Aspera arundinacea*, the pretty *Macrachloa tenacissima*, and *Acorus gramineus variegatus* were interesting, and a small specimen of *Pinus australis* was present.

S. W. FITZHERBERT.

## NOTES ON HARDY PLANTS

### HARDY FLOWERS IN SEASON.

**S**TERNBERGIA FISCHERIANA.—Owing to its free winter-flowering habit this is, perhaps, the most valuable of the many more or less distinct forms. It differs from the autumn-flowering ones in the distinct pale green foliage, usually contemporary with the flowers, which have a very short tube, and are erect, funnel-shaped, and pale yellow in colour, flowering throughout the winter till March.

*Colchicum libanoticum*.—This is one of the most showy of spring or winter-flowering plants. The corms (or bulbs) are small and oblong; the foliage is short and erect, enclosing the flower-tubes of two to twelve, or perhaps even more, erect bright rose-coloured flowers. This species is very hardy. I have plants here during frost that have not even lost the bright rose colour of the flowers, while another form had the open flowers destroyed. *C. Stevensii* is allied to *C. libanoticum*, but not so vigorous, and the leaves are linear and longer than in the

IN THE CHISWICK GARDENS: PLANE TREE AND COUNCIL HOUSE.

former. The flowers are very variable, ranging from rosy lilac to white, and appear from November till March. It is more tender than the former, and not so showy. *C. hololophum*, also known as *C. montanum* or *C. bulbocodioides*, might be best described as a miniature form of *C. libanoticum*. The corm is small, oval, and the erect leaves are linear-lanceolate. The flowers are smaller than in *C. libanoticum*, and are rose, with the tips of the segments paler. *C. luteum* is a very rare species; the only one with yellow flowers. The corm is oblong, and the leaves are linear. The flowers are small or intermediate, of a bright yellow colour. *C. crocifolium*.—The leaves are linear and slightly hirsute; the numerous small flowers are globular, white or flesh-coloured, the exterior of the segments brownish.

*Merendera caucasica*.—A fine and quite hardy plant, with an ovate corm like that of some of the small winter or spring-flowering *Colchicum* species. The leaves are recurved, and the pretty flowers are rose-coloured, not unlike those of *Colchicum libanoticum*. *M. robusta* has a small,

elongated corm, while the leaves are lanceolate, with serrulated margins. The handsome flowers are bright rose. This is the largest of the genus.

*Corbularia monophylla* (*Narcissus Clusii*).—Although the prettiest of the small genus *Corbularia*, this is comparatively seldom seen in good condition, owing, no doubt, to the fact that the bulbs do not ripen well in this country, and, unless grown under glass, imported bulbs (which are not always in first-class condition) will only flower once, and then either only produce leaves the following year or refuse to start at all, although the bulbs to all appearance are there and in good condition. The bulb is small, globular, with a hard black covering. Small bulbs often have only one leaf, but larger bulbs have from three to five filiform leaves from 9 inches to 18 inches long. Each bulb bears from one to three large funnel-shaped, pure white, slightly fragrant flowers. Potted up in September in light sandy soil, several bulbs in a pot, and grown in a cold frame, they may be expected to flower from about the end of December till March. If potted up still earlier, and after a while put in a gentle heat, they will flower in November.

*Iris Histrio* has an ovate bulb, covered with a pretty white netted tunic. The handsome, large flowers are pale blue, of which the upper part of the falls is beautifully veined and marked with white, with here and there a spot of yellow or red. Imported bulbs from the Lebanon flower the first year. If planted or potted up at once they flower usually at the end of December or January, but home-grown bulbs flower about February. *I. Vartani* is closely allied to the former, and flowers about the same time. It differs from *I. Histrio* in the shorter bulb, more erect, four-sided leaves, and purplish blue flowers, without the distinct veining of the former. In *I. histrioides* the bulb is similar to that of *I. Histrio*, and the leaves, which appear with the flowers, are nearly erect; the flowers are large and blue, the falls veined whitish or lilac. *I. histrioides major* is a form of which the flowers appear first and leaves follow. The flowers are not much larger than in the type, but are of a distinct bright blue, the falls slightly veined with white. If not quite so plentiful as the type, it is more vigorous and produces seeds more freely, bidding fair to become in time as plentiful as the former, of which at present the supply is kept up by annual importations. *I. sopenensis*.—The bulb in this form is small and oblong, and the leaves, which appear after the flowers, are very slender. The flowers are spreading, and the colour is a decided purple. This is a rare plant, but not as showy as either *I. Histrio* or *I. histrioides major*. *I. bakeriana* is a very rare and beautiful form of *I. reticulata*. The bulb is ovoid, and the leaves are cylindrical and with a horny point. The showy flowers are large, with the standards of a deep lilac, and the falls are deep violet, with marginal white

and yellow markings; violet-scented, as in the late-flowering typical *I. reticulata*. *I. reticulata purpurea* (*I. Krelagei*).—The commonest of this section; the flowers are very variable. When first opening they are deep purple, with a central golden-yellow ridge on the falls, changing, however, often to a pale or dull purple. They are not scented.

G. REUTHE.  
Keston, Kent.

THE CENTRAL WALK IN THE ROYAL HORTICULTURAL SOCIETY'S GARDENS.

### CHRISTMAS AND LENTEN ROSES.

HELLEBORUS includes both the Christmas Roses and Lenten Roses. Of the Christmas Roses the finest and most satisfactory were

the true *H. altifolius*, the most vigorous. In favourable positions the leaves attain a height of 3 feet, and the flowers appear from early November till March. I have a bed here unprotected which has been quite a sight through the whole winter, and, though I have cut many of the beautiful large white, slightly rose-tinted flowers, the plants still throw up new flowers. By covering the plants in flower with a hand-light, basket, or box for a short time the flowers come pure white. The next best Christmas Rose is the variety called *St. Brigid*. It flowers later, being usually at its best during December and January, and is not quite so lasting as *H. altifolius* or *maximus*, but it has long, bright green leaves and pure white flowers. Unfortunately, this plant is not quite so vigorous and often refuses to thrive, while the former will grow almost anywhere. The Lenten Roses are not at their best yet, although some of the *H. orientalis*, *H. colchicus*, and others have flowered since Christmas. There are no pure whites among these, only a greenish white, deep purple, reddish, and crimson spotted.

G. REUTHE.

### WINTER HELIOTROPE.

(*TUSSILAGO FRAGRANS*.)

This is a weedy plant, which in some parts of England has taken possession of whole hillsides. It is best grown in the wild garden or border, where it can be kept in its proper place. It is grown for its flowers, scented not unlike the Heliotrope, and appear throughout winter and spring. On the Continent, where the winters are more severe, the roots are put in boxes and forced for cut flowers.

G. REUTHE.

## ROSE GARDEN.

### FORGOTTEN ROSES.

It is not surprising that owing to the numerous new Roses many of the excellent older sorts have been crowded out. Beautiful as the Hybrid Teas unquestionably are, I think it will be a bad day for lovers of the Rose if they allow this group to drive out of cultivation many old and well-tried varieties of other classes that are too good to suffer extinction. I often wish there were a National Rose Garden, where every variety could be planted, so that rosarians could see for themselves the true value of each. How some of our much-praised Roses would have to give place to those less known but better, at least in the matter of "doing well" and in point of colour.

I append a list of a few varieties that are comparatively unknown, yet I can recommend every one with the full assurance that they would please the majority of the readers of *THE GARDEN*. Among what are regarded as climbing Roses not one of the Rambler race can surpass

*Mme. d'Arday*, with its great erect clusters of flesh-tinted flowers. It is very strong and very suitable for climbing over trees or for pillars.

*Robusta*.—As its name implies, this is a very vigorous grower, allied perhaps to the Bourbons, yet not so good in the autumn as the group generally. The colour is very vivid, just the tint of Louis Van Houtte. What a fine Rose to breed from!

*Joseph Bernacchi*, with its long buds, is as much a Tea Rose as *Gloire de Dijon*, yet it is grouped with the Noisettes, a somewhat mixed-up class to

what it used to be. This variety is very pale yellow, and a grand Rose for bold bedding. So also would be

*Germaine Trochon*, for it is one of that excellent type represented by *Gustave Regis* and *Billiard et Barré*, that flower freely upon long, erect growths, making them such excellent Roses for bedding where a tall grower is needed.

*Mme. Jules Siegfried* is one of the best climbing Teas, colour creamy white, foliage grand, and altogether first-rate, although not found in many catalogues.

*Monsieur Desir* is one of those Roses that possess just a tint of violet, a colour to which many object, but in reality the violet shade is an attraction, blended as it is with velvety crimson. The buds of this Rose are perfect and its foliage very beautiful. Why will not nurserymen grow such Roses

*Gloire des Rosomanes*. Seen at its best in autumn, it is a lovely Rose, of glowing colour and free, grand for bold bedding, low pillars, short fences, and any similar purpose or position. Another Rose closely allied to the Bourbons is

*Mme. Pierre Oger*, and it is one of the daintiest coloured varieties I am acquainted with; I may also say one of the most beautifully formed. Why cannot the National Rose Society institute a class for the most complete "collection of Roses seldom seen at exhibitions?" This would bring out many a gem that is unknown except to the few. In such a class there should be no limit as to how few flowers of each may be shown. A single spray of a sort would be sufficient in most cases.

*Mosella*.—One of a small group known as Hybrid Polyanthas—rather a misnomer, seeing that all are hybrids—but practically this Rose is nearer the Teas.

*Mme. Fanny de Forest*, a white Rose of exceptional merit, larger and better than *Boule de Neige*, and less inclined to malformation.

*Comtesse Panisse*.—One of the very best Teas grown. It is sturdy, of easy culture, and has thick-petalled, delicately-tinted flowers.

*Jean Pernet*.—A Tea Rose that is not grown half so much as it should be. It is vigorous, and the flowers are not inclined to split. Colour, a rich cream. A few good Hybrid Perpetuals will conclude my list. Foremost among these I may name

*Duke of Connaught*.—It is one of the most beautiful, with its crimson velvety shaded buds. It is a first-rate Rose for buttonholes.

*Mme. Joseph Bonnaire*.—A rival to *Paul Neyron* as regards size. A wonderful Rose when well grown. Perhaps rather addicted to mildew. The colour is silvery blush-pink.

*Mrs. F. W. Sanford*.—A counterpart of *Mrs. John Laing* in all save colour. This is very delicate blush white. Certainly a Rose to be planted freely where the older sort is valued.

*Mme. Eugene Fremy* is another of those extra large showy Roses of which *Paul Neyron* is a type. If they lack something in refinement, there is that sturdy vigour about them that one admires so much in garden Roses.

PHILOMEL.

BENNETT'S SEEDLING ROSE OVER AN OLD TREE.

upon standards? They make far better heads than the dumpy *Xavier Olibo* type.

*Fanny Stolwerck*, with its mixture of copper, yellow, salmon, and carmine, is very charming, but it is scarcely known.

*Le Soleil* is quite good enough for exhibition, and as a yellow Rose is first-rate. The texture of the petals is remarkable. I prefer this to the tender climbing kinds, such as *Henriette de Beauveau*, even though the colour be not so intense.

*Queen of the Belgians* is an Ayrshire Rose that few growers are acquainted with. In refined form and delicacy of colouring it reminds one of the Tea climbers. It is excellent for pergolas, &c. There seems a general desire for brilliant scarlet and crimson flowered Roses, yet how few there are who plant

freely over some support, to smother it with healthy green shoots and clusters of lovely blossoms. The variety of supports that may be used is endless, but few give more pleasing results, because of its simplicity and naturalness, than a worn-out tree made to bear a wealth of blossom not its own. Instead of destroying old trees when they die from old age or disease, how much better it would be to allow some strong climbing Rose to hide their ugliness and transform them into objects of delight—that is, supposing them to be conveniently and pleasingly situated. Bennett's Seedling is a good Rose for this purpose, as the illustration shows, and others that occur to one as equally suitable are *Aimée Vibert*, *Reine Olga de Wurtemberg*, *Reine Marie Henriette*, *Crimson Rambler*, and *Longworth Rambler*. The

### BENNETT'S SEEDLING ROSE OVER AN OLD TREE.

THERE seems to be no limit to the usefulness of the Rose; it can be planted to advantage in perhaps more positions in the garden than any other flowering plant. It is rarely more admired than when some strong-growing variety is allowed to climb and clamber

removal of a good-sized tree is always a matter for regret, and leaves a blank that one does not easily become accustomed to. Why not allow the tree to remain; not, however, gaunt and leafless, but clothed with flowers and foliage that shall give it such a beauty as it never had before?

## ROUND ABOUT A GARDEN.

### THE EARLY PRIMROSES.

THE persistent and prolific flowering of the Primroses this year has been a feature by which the records of many of our shrubberies will probably be headed for many years to come. It is not often in a century that a garden on the bleak East Coast will yield you Primroses for every day, from the week before Christmas onwards to the spring. But the really curious point about the flowering of the Primrose this winter has been the abundance of blossoms in aspects facing north and east. Ordinarily, of course, the earliest spring flowers must be sought in some sheltered southern aspect, but this year the clumps that usually dare not push forth a bud until spring sets in "with its usual severity" in mid-April have been starred with many blooms, all through January and February, while the plants enjoying better situations, facing the warm south, are scarcely so forward as they were last year or the year before at this time.

### A CONTRAST IN SITES.

Although this contrast seems curious, it is not really so. That which regulates the periods of all life in animal or plant upon our exposed coasts is the prevailing wind, and the nip of a wintry north-easter once a week suffices to keep all the spring flowers marking time. This winter, however, we have had no north-easters. Day after day and week after week the weathercock has pointed west or south, or some variant thereof, and, though frost has been rare, the plants enjoying the mild aspects have been constantly reminded to hasten slowly. Those, on the other hand, which in ordinary winters have had to take the consequences of clinging to existence on slopes exposed to blasts that come straight from the North Pole or the Siberian steppes have hardly known this winter that any wind was blowing, since they could not hear it whistling in the shrubbery behind them. No wonder, then, that they mistook January for April.

### THE SPRING FLOWERS' ENEMIES.

But no matter where or when your Primroses or any other early spring flowers may appear, the birds find them out, and it is a sore trial for a lover of the birds to watch a blackbird idly snipping off the heads of Primroses as a sort of relief to the serious business

of worm-hunting. You may see a cock sparrow, too, sitting puffily on the ground, chirping at intervals to a friend upon the roof, and, between chirps, snipping off a blossom or two with that inconsequence which makes the sparrow's ravages in a garden aggravating out of all proportion to their actual importance. So one gets into the habit of putting much more blame upon the sparrow than he deserves. Some, no doubt, of the scattered blooms of Primroses, Irises, and Snowdrops are his work; indeed, you have seen him at it. But, as diurnal animals, we human beings see only one half of Nature's work, and if we had the eyes of owls and could watch the hosts of mice and voles that scuttle about our shrubberies at night, and see the dainty way in which they nibble off the heads of our flowers, we should begin to realise that "those sparrows" are not as black as indignant fancy paints them. Patent self-setting mouse-traps, and plenty of them, form one of the best recipes for abundance of early flowers in a

the sparrow's beak against it, is merely its earlier appearance.

### FAMILIARITY BRINGS SAFETY.

When the yellow Crocuses first appear they are the first very conspicuous innovation in the garden, and the sparrows—of whom the majority are young birds of last year, and have never seen a Crocus before—naturally wish to discover their dietary qualities. By the time the white and blue Crocuses are in full bloom all the sparrows about the place have learned that it is waste of time to snip off Crocus blossoms when there are all kinds of other things pushing up out of the ground and the air is getting more full of tasty insects daily. And from then onwards the sparrow ceases to aggravate by his assaults upon the flowers, and becomes instead one of the most useful of birds, devouring all sorts of insects all day long.

### A HUMAN PREJUDICE.

From this point of view the fault of the sparrow in

ANEMONE PATENS.

country garden. Still, leaving as wide a margin as we may for the depredations and mischief of these little rodents, the sparrow's offences at this season are too flagrant to be condoned. I do not know exactly why it is, but a row of yellow Crocuses, which might be a great joy to behold, lose almost all their charm when strands of black cotton are stretched along them to keep off the sparrows. Yet there are many gardens where, without black cotton, yellow Crocuses can only be seen lying decapitated on the mould. The reason why the sparrow attacks the yellow Crocuses, and leaves the white and blue comparatively untouched, has often been sought in supposed differences between the edible qualities of the flowers and in connexions of ideas which the colours might be supposed to suggest to the sparrow mind, but I am inclined to think that the misfortune of the yellow Crocus, the peculiarity which arms

the spring garden is his enquiring mind, and, as it is only by possession of the same characteristic in a more marked degree that Man has won his way to the very top of Nature's genealogical tree, we might expect to feel the more kindly disposed towards the sparrow's mischief in his search for knowledge. But, just as that which irritates us most in viewing a monkey is its likeness to ourselves, so it seems an aggravation of the sparrow's iniquities that he conducts them with a cunning that has something human in it. E. K. R.

## AN ARTIST'S NOTE-BOOK.

### ANEMONE PATENS.

A DISTINCT form of Anemone Pulsatilla, with longer and more pointed flowers than the type. The growth is stronger and the flower larger than in the species. This, like A. Pulsatilla, is well suited to the border, and if planted in deep sandy loam will quickly become established and increase in vigour each year. The flowers are purplish. This group of Anemones is of much interest in the rock garden too, and I have grown them for many years in a sunny nook, where the plants make bold handsome tufts. V.

## THE FRUIT GARDEN.

### THE PROMISE OF NUTS.

IT is early yet to talk about the prospects of fruit crops in the coming season, but the Cobs and Filberts have already unfurled their little brush-like female blossoms, and, judging from the quantity, they represent a promising show. Greatly as Cobs and Filberts are prized on dessert tables generally in the winter, not much real attention is paid to their culture in the majority of gardens. The credit of growing Nuts on a clearly-defined principle must be given to the Kentish fruit farmer in the districts where this crop is largely represented.

In Kent Cobs and Filberts do well, and are perhaps better treated here than in any other part of the country, but, like other crops, they seem to have their own particular localities, outside of which they are rarely seen. Quite recently I journeyed through that part of Kent which lies between Maidstone and Tonbridge. How long Nuts have formed a staple market crop in this locality it would be hard to say, but a plantation of Cobs will go on for many years under the care of a skilful pruner. On the fruit-covered slopes on the Mereworth Castle estate and in the neighbourhood there are veritable patriarchs in the way of trees, judging from the knotted and goarled condition of the main stems. In the sandy soil round Igham and Wrotham Heath Nuts in many instances form the entire crop.

At the time of the visit referred to the pruning was just completed, and the stiff outline of the closely-cut bushes was relieved by the presence of the male catkins hanging gracefully from the twigs and shaking to and fro in the breeze. At first sight it might appear as if the Kentish Nut pruner were too severe with the knife, but he knows his business, and a closer examination reveals the presence of an abundance of little pink flowers on the twiggy shoots with which the main branches are furnished, as well as a reasonable proportion of male catkins left for fertilising. It is in the early years of its life that the Kentish Nut bush receives its somewhat severe training, and when it has reached the desired size it is not allowed to extend much further. Most of the bushes are shaped like an inverted basin or saucer, with the centre quite open and the main branches springing from a central stem. While the bush is young and when the shoots are pliable the latter are compressed into the desired form, and so the specimen gets its shape, which it never loses afterwards unless it is neglected in the way of pruning.

Only men who are skilled in the work are allowed to knife the Nuts, as judgment is required in cutting, and the pruners go over the main branches one by one with knife and saw, removing all rank growth springing from the centre of the bush, sawing back old dead spurs and shortening all strong lateral shoots, but taking care to preserve the short twiggy growths along the branches. The system is by no means new—in fact, it seems to be half as old as Time itself—but it appears to belong to the county, and I cannot help thinking that it would be a good plan if it could be put into practice in private gardens in other parts where Cobs and Filberts are grown. Cobs are not an expensive crop to grow, and apart from the annual pruning little labour is spent on them. The ground beneath the bushes is kept under cultivation by digging and hosing, but little in the way of manure is required, as this would lead to the production of rank growth, which is undesirable. In many plantations where standard Apples and Plums are grown between the Nuts, the former are manured and the latter get quite as much food as is good for them from the dressing.

Finally, one gathers the idea that a special pride is taken in the Nuts, and it appears to be an understood thing that no part of the general routine of culture must be neglected. Doubtless the knowledge of what would happen in the event of neglect is responsible for the feeling, which is not shared with all fruits, as I have passed through many

plantations in which the Nuts were neatly and properly pruned, and yet the heads of the standard Apples and Plums above represented sheer thickets of growth, and were literally spoiling for the want of timely thinning. Still, whatever may be said about the methods of British market fruit culture and the room for improvement, it must be said that the Kentish Nut grower, taken as a whole, is master of his business, and under his treatment the crop, one season with another, is a source of profit to him. The early promise of 1904 is encouraging, and it is to be hoped that it is a good omen for a better fruit year generally than its predecessor.

G. H. HOLLINGWORTH.

## ORCHIDS.

### CYMBIDIUM GIGANTEUM WILSONI.

AMONG the Orchids shown at the last Drill Hall meeting of the Royal Horticultural Society few attracted more attention than the new Cymbidium, collected in China for Messrs. James Veitch and Sons, Chelsea, and exhibited by them. Orchids introduced for the first time from their native habitats are sufficiently rare to make them more than ordinarily interesting. Mr. Rolfe has classed this new Cymbidium as a variety of *C. giganteum*. The recorded habitat of this species is Northern India, and the date of its introduction 1837. Nicholson calls it "a strong and bold-growing species," a description that would scarcely apply to the variety *Wilsoni* as exhibited at the Drill Hall. A number of experts seemed to think it sufficiently distinct to merit specific rank. The flowers show an attractive association of colouring; sepals and petals are green spotted with brown, while lip and throat are white, heavily marked with chocolate-red.

### WELL-GROWN LYCASTES.

It is rarely that one sees such fine plants of *Lycaste Skinneri* and *Lycaste aromatica* as were shown on the 23rd ult. at the Drill Hall by Mr. F. Du Cane Godman, South Lodge, Horsham. Each plant carried some two dozen blooms or more, and, in company with a plant of *Platyclinis glumacea*, also shown by Mr. Godman, came in for much admiration. The flowers of *L. aromatica* have a curious spicy scent, while those of *Platyclinis glumacea* are so strong and sweetly fragrant as to be noticeable many yards away. The *Lycastes* are natives of Central America chiefly, and are of easy culture, doing best in an intermediate temperature. There are now many beautiful varieties of *Lycaste Skinneri*, distinguished by such names as *delicatissima*, *purpurata*, *superba*, *rosea*, *virginalis*, &c. Mr. G. Whitelegge, gardener to J. Bradshaw, Esq., The Grange, Southgate, exhibited two lovely forms of *L. Skinneri* last week at the Drill Hall. They were called respectively *Beauty* and *Enchantress*, and were of fine form and delicate colouring.

A. P. H.

### WORK FOR THE WEEK.

#### DENDROBIUM PROPAGATION.

To secure good plants before next winter it is necessary that this matter should now be taken in hand. Bulbs that were taken off, as advised in a previous calendar, will now be ready for cutting up; each joint that has not produced flower will make a young plant. I prefer cutting them into single eyes, cutting them rather close to the eye, to allow of the major part of the severed bulb being below the eye to help sustain it, and also to allow of sufficient material to insert without covering the dormant eye.

A simple and safe way to propagate is to make 4-inch pots half full of crocks, over which place some sphagnum, and then fill up with a mixture of two parts sand and one part fine chopped sphagnum. Gently press in the cuttings, not inserting them more than is necessary to keep them upright. Each should then be correctly labelled, and placed on a shelf or similar place in a hot, moist house

where they will be shaded from strong sunshine. Keep the material dry, on bright days giving them a slight spraying over.

Those having bottom-heat and a small case would be able to produce plants much more quickly. In preparing a case it is quite necessary to see that there is no moisture-giving material between the pipes and the cuttings. The case should be filled up to nearly the desired level with crocks, over which place some sphagnum, enough to prevent the sand from working down amongst the crocks, and then place about 1 inch of the sand and sphagnum mixture as advised above. The space should then be divided with stakes laid flat, so that there is only one variety to a section. The cuttings should then be inserted in the same way as when placed in pots. To enable the cuttings to break quickly a good deal of moisture is helpful. Sufficient is generally obtained by keeping the case closed by day and open a little each night, spraying them lightly over on very bright days; but the material must be kept nearly dry. It is far safer to lay pseudo bulbs on a stage for a few weeks before cutting them up.

When the young growths have attained the height of 1 inch they should be potted up in a mixture of one part each of chopped peat, sphagnum, and coarse sand, using very small pots. The earliest ones, if kept in a good hot-house, will often make the first bulb by the end of July. I strongly advise the propagation of a few each year, and when space is a consideration discard some of the old plants.

#### EPIPHRONITIS VEITCHII.

The brilliant flowers of this hybrid always brighten up a house, especially during the winter months. By removing the flowers during the late summer months it can generally be made to flower during February and March. Like *E. radicans*, one of its parents, it should be placed in strong light. The coolest end of the *Cattleya* house suits it well as regards temperature, and during bright weather it should be kept well syringed. Potting may be done at almost any time in a mixture of two parts moss to one part peat. The stock may be increased by taking off the aerial growths and potting them up separately.

Gasston Park Gardens, Reigate. W. P. BOUND.

## THE KITCHEN GARDEN.

### NEW LETTUCES FROM MANCHESTER.

MESSRS. DICKSON AND ROBINSON showed at one of the meetings of the Royal Horticultural Society in the early autumn three new varieties of Cabbage Lettuce, and these were so good that a note at this season concerning them may not be out of place. Two of these, Lord Kitchener and Staghorn, received awards of merit at the great vegetable show at Chiswick. The third variety, Distinction, was seen in splendid condition when shown at the Drill Hall earlier in September, this firm at that date staging no less than sixty-nine varieties. Lord Kitchener is a medium grower, with solid heart, the leafage is of a delicate yellowish green colour, and, what makes it more valuable, it remains good for a long time after being fully matured. This is a great advantage in a summer Lettuce, as some of the older varieties bolt so quickly. But the most important point growers have to consider with new vegetables is the flavour. Certainly Lord Kitchener is not behind in this respect. It is of exquisite flavour, the leaves are crisp, and the plant builds up solid hearts, having very few outer leaves.

Staghorn is quite distinct from the last-named, and doubtless takes its name from the cut leaves. These are pointed and lacinated, and have a very attractive appearance; indeed, it might at first sight be taken for a well-grown Endive. The growth is very compact, and it makes an excellent salad or garnishing plant. For the salad bowl this should be most valuable, the hearts being very solid and white, while it should also be useful for exhibition. In quality it is not unlike a good Endive. This

variety was much admired in the collection referred to, which so deservedly won a gold medal.

The other Cabbage variety, named *Distinction*, is, in my opinion, well worth bracketing with *Lord Kitchener* and *Staghorn*. It is a much larger Lettuce, and size is valued in many gardens if the quality is good. It is remarkable for its sweet flavour, bright green colour, and its long standing. It is very slow to seed, and being a rapid grower makes a splendid summer Lettuce. This should make a valuable market sort.

I now come to the Cos varieties, and in Messrs. Dickson and Robinson's collection there were two that stood out prominently, viz., *Dickson* and *Robinson's Giant Market* and *Little Gem*; these in appearance differ greatly, but are most valuable additions to the Cos section. I do not think that in private gardens the Cos has so many admirers as the Cabbage Lettuces, and this is owing to the more rapid growth and compact habit of the latter. Those who like this type will find in *Little Gem* a valuable early variety, and most serviceable either for frame culture or earliest supplies on sheltered borders. I am aware that we have some very good Cos Lettuces in the older varieties, such as *Superb White* and *Mammoth White*, *Ivery's Nonsuch* and *Balloon*, but no matter how good these are, superior new sorts are welcome. It was a great surprise to growers to see so many really excellent varieties, both of Cos and Cabbage Lettuce, as shown by Messrs. Dickson and Robinson.

The *Giant Market*, as its name implies, is sent out as a superior market variety, and in these days, when so many growers sell their surplus supplies, it may be termed a profitable variety on that account. A Cos Lettuce that has large and broad leaves to be profitable should be compact, the foliage should not require tying. The *Giant Market* possesses these good points, and in addition is very slow to run to seed. The flavour is very good, the leaves remarkably tender and crisp, and the hearts attain a large size. *Little Gem*, as its name implies, is small though good, but I am not sure that this name is the best, as there are others called *Little Gem*, and it is such an easy matter to get confused. The variety in question is a splendid addition on account of its size and earliness. It is dwarf, self-folding, having yellowish green leaves, and of splendid quality. It requires very little space, and one plant often makes two or three distinct growths. It makes a most useful salad Lettuce in the early spring. It is also valuable for autumn sowing. G. WYTHES.

## CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

### FRUIT TREE PRUNING.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—Messrs. Thomas and Tallack have recently had considerable wordy warfare in the pages of *THE GARDEN* upon the above subject, ostensibly for the edification of the amateur cultivator, who has my entire sympathy when he endeavours to put such conflicting statements into practice. He may well exclaim "When doctors differ who shall decide?" The fact is that in this controversy extraneous matter has crept in for summer and winter pruning, and various forms of tree pruning have become muddled up together. Consequently, both combatants are right in some points and both wrong in others; indeed, as is usual, the real truth lies between the extreme views advocated. I have long advocated true extension pruning to the fullest extent of that method, but I certainly cannot agree with Mr. Tallack (page 402, vol. lxiv.), where, in speaking of a young tree, Apple, Pear, Plum, or Cherry, two or three years planted, he says: "Let the annual leading shoots remain intact, confining the pruning to cutting clean out any useless or badly placed shoots." Whether summer or winter pruning or both is not clear. He also repeats an assertion (page 44):

"That the knife applied to the main leads never yet assisted in the production of fruit-buds on a tree that has not reached its prime." Possibly not, neither is it desirous for our young tree only two or three years planted to produce flower-buds so profusely. On the contrary, we should remember rather that we are only laying the foundation of a permanent character, and our chief object should be to build up our model tree with stout and strong well-regulated branches, every one of which should ultimately become a perfect cordon of fruit-spurs from base to summit, capable of rigidly supporting its allotted weight of high quality fruit without danger of breaking off.

Now let us take the case of Plums in particular. Where frequently shoots or leads are annually made at this stage 4 feet, 5 feet, and upwards in length (strong-growing varieties of Apples and Pears nearly as much), it is our experience that if these leading shoots or leads are left intact and not shortened at all at the winter pruning (they should not be stopped at the summer pruning) these foundation or principal branches are seldom sturdy or strong enough to carry the necessary weight of fruit over the ripening stage

MR. S. T. WRIGHT.  
Superintendent of the R.H.S. Gardens, Chiswick.

in years to come without breaking off, and the consequent loss, with permanent injury to the tree. The lower half of these unstopped long shoots seldom breaks or forms spurs or other growth, but remains bare for ever. On the other hand, if these long shoots or leads are at the winter pruning shortened, not exceeding one-third of this from foot-growth, and always cutting to an outward pointing bud, better results will be obtained and the above dangers avoided. This treatment cannot be considered hard pruning, but really the truest form of extension pruning for such trees of the aforesaid age.

We also cannot concur in the statement of "confining the pruning to cutting clean out," &c. Now really with the above kinds of trees and at this age there cannot be anything worth mentioning to cut clean out, but we prefer to stop all lateral growth not required for leads to about three or four full-sized leaves about the end of July or August, according to season, so as to admit air and sunlight into the middle of the tree to assist in the thorough development of the fruiting spurs, and to prevent a waste of power in permitting growth which would necessarily have to be removed at the winter pruning. Of course, the leaders are all left unstopped at this summer pruning; moreover, they act as a kind of safety valve, and generally prevent the growth of sub-

laterals—i.e., the secondary growths of those recently stopped laterals.

There are other reasons for removing the tips or extremities of the leaders. One reason is that quite the tips of the shoots are formed too late to become thoroughly ripened, and it can hardly be expected to get clean, kindly shoots from unripened wood, especially in the choicer and more delicate varieties. Besides, if there should be any insect pests about, such as the winter moth or allied species, which lay their eggs in the autumn or early winter months, it is in the scales or tips of the unripe shoots that they are usually deposited, but which this shortening removes. The growth that follows is certainly of a more kindly nature, leading to infinitely better results than leaving the leading shoots intact.

The foregoing is a summary of my own very long experience; it has been part of my duty for upwards of twenty-one years to raise the trees and establish fruit orchards for tenantry on a large scale for commercial purposes in the most expeditious manner; upwards of 20,000 fruit trees, chiefly standards for orchards, have been dealt with.

Madresfield Court.

W. CRUMP.

### CLEARING ROUGH WOODLAND.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—The clearing of rough woodland or open coppice of noxious weeds and other objectionable growths is by no means so formidable a task as you state in reply to a correspondent in *THE GARDEN* of February 20. Here on the Kentish uplands we are used to that work. I have a piece in hand now which was planted with fruit trees after the wood was cut, and then for two years allowed to go wild, though that is not a usual practice. The Brambles and other rubbish have overtopped the fruit trees, but I am both clearing and leaving the ground fit for cultivation between the trees. The method is to grub out all small roots as one goes, except old Oak stools, which would take too much time and can be buried. Then, a trench being opened with a short, strong fork, get the top 3 inches or so off and throw it into the bottom of the trench. Then put the fork into the ground beneath as deep as possible, and turn it over on the top of the surface-soil. This leaves a clean, level surface, which can be hoed in the usual manner, thus securing a perfect clearance at once. Of course, deeper pick and shovel trenching is better, but would cost much more. The roots are not much of an obstacle. I could not say what it would cost per square rod without seeing it, but at the worst, with proper tools a man would clear and finish a rod per day. J. A. NOTMAN.

Hurstcot, Wigmor Chatham.

### CARNATION SOUVENIR DE LA MALMAISON OUT OF DOORS.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—Being greatly interested in Mr. Coomber's notes of the 20th ult. (page 140 of *THE GARDEN*) respecting the *Malmaison* Carnation, I was much surprised to hear of the success met with. I am curious to know if it was the old blush or pink variety, as these two, I find, are the most difficult to grow. The newer varieties of *Malmaisons* are much more robust and vigorous and easier to cultivate, although, on the other hand, they need much attention. Respecting what Mr. Coomber says of exposing the plants in the summer months, I have practised layering them entirely out of doors about the middle of August, and have always met with good results, but I must say that layering in a cold frame lightly shaded is best. I strongly advocate growing *Malmaisons* on a staging covered with sifted ashes, in a well-ventilated house, and in very hot weather. I find damping lightly between the pots every day and about twice a week or more (according to the weather) overhead with the syringe suits them well. Of course, at the flowering stage this syringing must be abandoned.

Corwen.

J. S. HIGGINS.

## GARDENING OF THE WEEK.

## FRUIT GARDEN.

## POT VINES.

**P**OT VINES which were started early in November should be given liberal supplies of weak liquid manure water and occasional sprinklings of Thompson's Vine Manure. Manure water should be discontinued when the fruit approaches ripening. Give the laterals more liberty at this stage above the bunches wherever space will allow. If red spider makes its appearance the leaves must be sponged at once, and if done carefully no injury will be done to either fruit or foliage. Give a little ventilation early in the day, and add more as the sun-heat increases; close early, and take advantage of bright sunny days to hasten the crop, but do not increase the night temperature above 65° or 68° on mild nights. Damp the paths and walls, using weak liquid manure occasionally.

## EARLY PEACHES.

Fruits in the early house will now be swelling freely. The trees must be well syringed twice daily on bright days, once being sufficient on dull, cold days. The fruits should be left about 1 foot apart on old trees, and a little less on young, vigorous trees. Tie down the shoots as they progress, removing any superfluous growths as the work proceeds; 6 inches to 9 inches apart is none too much. Stop extra strong-growing shoots on young trees to secure a more even flow of sap. The night temperature may now be increased to 60° at night, closing early, and allowing it to rise to 75° or 80°. Syringe the trees occasionally with clear soot water. Old trees should be mulched with manure and fed freely with diluted liquid. Young strong-growing trees do not require it.

## SUCCESSION HOUSES.

Pay attention to the disbudding of these trees, but do not take off too many shoots at once, especially if the trees are weak, or this will cause a check to them. Later trees as they approach the flowering stage should be fumigated moderately for green fly, or this may ruin the crop later. Peaches set very well on healthy trees in a temperature of 50°, but it is always best to pass the brush over the flowers every day. Do not syringe the trees while in bloom.

## FIGS.

Little progress will be noticeable with the earliest trees until the fruits are set, but as soon as they begin to swell a rise of 5° in the temperature should be given. Thin the fruits freely, and do not overcrowd the shoots. Liquid manure water must be liberally supplied to the borders if the drainage is good; syringe the trees twice daily.

*Impney Gardens, Droitwich.* F. JORDAN.

## FLOWER GARDEN.

## HEDGES.

If any growth was made after the autumn pruning Holly hedges may now be clipped. By the time fresh growth is made there will be no danger of frosts sufficiently severe to do any damage. Unless great care and judgment are exercised, hedges soon become too broad, and not only occupy more than the allotted space and root room, but have a tendency to become very thin. The surface soil should be pricked over, and all weeds eradicated. When a large and not too formal hedge is required the common Rhododendron ponticum is good, that is providing the soil will grow Rhododendrons. Such a hedge becomes in a few years a remarkably beautiful sight when in full bloom, and a little judicious pruning when the flowering is over will keep it in shape. As a boundary to the Rose garden the

## SWEET-BRIAR

makes a capital hedge, and will stand a deal of hard pruning. The Penzance Briars, Rosa rugosa, and its varieties and hybrids are also beautiful and useful for this purpose. The various forms of Pyrus japonica make a very pretty deciduous

hedge. If, after the hedge has reached the desired size, summer pruning is practised it will soon come into flower, and there will be buds or blossoms all the year round.

## BY THE SEASIDE

Escallonias make splendid hedges, and will stand a good deal of wind. For a low evergreen boundary many of the Ivies are useful. If a quickly-established wind-screen is required, such subjects as Cupressus lawsoniana, Thuya japonica, Hornbeam, Beech, and Whitethorn should be planted. The Myrobalan (Cherry Plum), when established, makes an almost impenetrable barrier, and during April or early May such a hedge in flower is very attractive. The planter will be guided in his selection by the soil and locality; but, whatever is planted, the preparations must be thorough.

## VIOLETS.

All protecting material should now be cleared away. Remove all decaying leaves and stir the surface soil. At this time of the year a few bright days quickly bring the Violets into flower. The flowers required for decorative purposes should be gathered during the afternoon and placed in water, selecting those not too fully developed. Any plants that are growing at the foot of a wall or in a dry place will greatly benefit from an application of weak manure or soot water.

## FLOWERING SHRUBS.

As they pass out of flower, such spring-flowering shrubs as Chimonanthus fragrans, Jasminum nudiflorum, Hamamelis japonica, &c., should receive the needful pruning. The present is also a good time to give, where necessary, a top-dressing or mulching.

A. C. BARTLETT.

*Pencarrow Gardens, Bodmin.*

## KITCHEN GARDEN.

A WELCOME change in the weather has set in, and the past week has been fairly dry with several hours' sunshine each day. Many things have started into growth, and the kitchen garden now begins to claim considerable attention. All digging should, as far as possible, be finished, and plans will have to be laid as to how the garden is to be cropped. No difficulty will be experienced where the ground has been prepared for special occupants, but the remainder must be carefully thought of, and things arranged in proper order, warm and sunny borders being used for all early crops, and where there are shady and moist plots they should be used for autumn and winter crops.

## POTATOES.

Some tubers of early sorts may now be started with a view to planting them out of doors in some sheltered position. These ripen very quickly where it is possible to plant them close to the bottom of a south wall. This plan is adopted in many gardens with good results. A good planting should be made now on a southern border where the soil is rich and light. Sharpe's Victor, Harbinger, or Early Sandringham are all suitable for early work, as well as many other varieties. Choose a good dry day for planting, and draw the soil well over the sets so as to form a slight ridge.

## ONIONS.

On the first favourable opportunity this important crop should be sown. It is necessary that the ground be in good condition—dry and friable. A slight sprinkling of soot and wood ashes should be given and raked in before sowing. The ground, if at all soft, should be trodden until very firm. The drills should be drawn 15 inches apart, and after sowing filled in with the feet and again trodden. The plot may then be lightly raked over. As success with this crop to a great extent depends on the condition of the soil, it is advisable to put off sowing till a suitable day comes round. A selection of varieties of good keeping qualities should be made, and also some of the red sorts. The latter are preferred for pickling.

## VEGETABLES UNDER GLASS.

Carrots, Turnips, and other early vegetables growing in pits are now making good progress, and

should be aired on all favourable occasions, as the plants grow and begin to get crowded. They must be thinned before they get drawn and weakly. Potatoes growing in pits will also require air in the warm part of the day. Those growing in pots, if removed to a cooler house as advised, will have a fine healthy and sturdy appearance, and may now be given an application of weak liquid manure from the farmyard, or a good fertiliser when watering. Early Peas in pots may also be given a slight stimulant.

THOMAS HAY.

*Hopetoun House Gardens, Queensferry, N.B.*

## INDOOR GARDEN.

## ROSES IN POTS.

AIM at promoting a well-developed, short-jointed growth by elevating the plants near the glass and affording them full exposure to light, air, and sun. The soil must never be allowed to get dry. The development of the flower-buds will be greatly assisted by applying cow or sheep manure liquid about twice weekly, with during the season two doses of sulphate of ammonia, made into a liquid by dissolving one tablespoonful of the sulphate in one gallon of water. Syringing the plants occasionally with Bentley's Insecticide will free them of green fly and grubs, and will aid in the satisfactory development of growth. Immediately mildew appears dust the affected parts with dry flowers of sulphur. Much the same remarks will apply to Roses that are planted out, except that a surface mulching with good cow manure will be necessary.

## PALMS.

For several months during the winter season these plants have in many gardens to submit to somewhat harsh treatment, and about this time of the year begin to deteriorate. The dust that settles upon their fronds and leaves when in rooms cannot always be washed off, and this naturally clogs the pores of the leaves and prevents proper respiration. The yellow spotting so frequently seen upon the fronds of Kentias is the result mainly of the circumstances mentioned, as well as of cold draughts. Directly opportunity offers remove them to a position where they can be given a temperature of 60° to 65° and be syringed twice daily. Sprinkle Clay's Fertilizer at the rate of a teaspoonful to a 12-inch pot over the surface soil about every two weeks, and afford an occasional dose of weak soot water to their roots.

## IXORAS.

Specimen plants that have been pruned back previously with a view to creating new growths will by this time be ready for repotting. A capital compost for the purpose is formed of fibrous peat and loam and a small proportion of coarse sand. Remove a portion of the old soil and return them to pots that are large enough to carry them well through another season. Until the plants begin to root into the new soil apply water very sparingly to their roots, but syringe freely the growth, and give a temperature of 70° to 75°. Directly they are ready take off the tops of a few of the strongest shoots, and insert these as cuttings singly in 2½-inch pots. Plunge them in a brisk bottom-heat, and for a time keep them close and shaded from strong sunlight, but immediately they are rooted remove the shade and afford light and air to strengthen them. *Ixoras Williamsii*, *Coccinea*, *Fraserii*, *Pilgrimii*, and *Duffii* are the best.

## BOOKS.

**Pictorial Practical Chrysanthemum Culture.**—This is another of the series of handbooks which aim at teaching largely by means of sketches and diagrams, instead of relying solely upon reading matter. It is very comprehensive; in addition to the ordinary cultural details, which are clearly explained, there are "Hints to Exhibitors," including advice as to

\* "Pictorial Practical Chrysanthemum Culture." By Walter P. Wright. Cassell and Co

preparing blooms for the show-board, and valuable information as to the best dates for taking buds. There are selections of Chrysanthemums for special purposes, as scented, curious, and hairy Chrysanthemums, varieties for market, buttonholes, &c. There are also numerous illustrations, showing groups of Chrysanthemums, various types, &c., which add to the value of a useful little book.

**Roses and their Culture.**\*—This is a handy little book for amateurs, and contains sound advice from one well qualified to give it. There are lists of Roses for various purposes, and many practical chapters about budding, destroying insect pests, and so forth, with a schedule of all the varieties worthy of culture in British gardens, whilst interspersed here and there are excellent illustrations. The whole get-up of the book, however, is poor, the cover is ugly, the printing indifferent, and at the end are several pages of advertisements. The author deserves better treatment. A coloured plate of Mme. Chauvry variety is not bad, but better to have left this out and expended more care upon the general production.

**Fertilisation of Orchids.**†—We welcome a cheap edition of this great work. We need say no more; it is a book for the student and all for whom the workings of Nature possess any fascination. It is to be hoped the publishers will see their way to issue the whole of Darwin's works at this price. The book is excellently printed, well bound, and the illustrations are as clear as in the original editions. A very cheap and notable edition.

## POTATOES IN LINCOLNSHIRE.

**S**PALDING is the "eye" of the Potato world, and during the past few months it has, of course, taken the liveliest interest in watching and profiting by the rise in the price of new varieties. Among other seedsmen and growers of the "Metropolis of the Fens" who have come into public prominence is Mr. George Massey. In a recent letter to the writer, Mr. Massey mentioned that he was actually selling—not offering for sale—single tubers of Eldorado at £10, none of which weighed more than 1½oz., and as the majority

weighed exactly 6oz. Indeed, public auctions have been held—at Lincoln, if I remember rightly—where the goods to be put up for sale consisted of a few small specimens of this self-same Potato. As to the value of the half-dozen shown in the photograph, Mr. Massey declares that they are worth £500, or nearly £84 a tuber.

An interesting fact in regard to the culti-

which were planted last year, it is even now fetching from 3s. 6d. to 4s. per pound.

Of the variety *Sim Gray*, introduced by Lord Carew, and for which £5 has been paid for one pound, not so much has been heard, although the price quoted is, as far as I am aware, five times higher than that reached by the *Northern Star*. Nevertheless, it has its devotees, like the rest, and in the present

POTATO SIR J. LLEWELYN.

vation of the *Eldorado* is that it was grown by not more than three raisers, the fortunate few being Mr. Findlay, Mr. Massey, and Professor Malden, the very well-known Potato expert. In October the last-named gentleman stated that from 124 *Eldorado* plants he lifted 536lb., all the tubers being quite free from disease.

The introducer of this plutocratic Potato was Mr. Findlay of Markinch, in Scotland, from whose nursery have come many other well-known varieties, notably *British Queen*, *Evergood*, *Up-to-Date*, *Empress Queen*, and *Northern Star*. Mr. Findlay is a raiser with a long and wide experience being old enough to

year it may possibly boom itself into general favour.

Another new Potato which played a part in the record boom of 1903 was *Sutton's Discovery*, which South Lincolnshire folk are now buying at £1 per pound. This is a price that, when paid for the *Northern Star* twelve months ago, made most growers gape with astonishment and cry out that the buyers must, indeed, be mad. Time, however, has proved that they were simply shrewd.

In regard to their selling figure, Sir John Llewelyn and the *Evergood* sink into insignificance when compared with those of the others already mentioned, as they have been fetching not more than £25 and £8 per ton respectively. But, according to the *Spalding Free Press* of the 2nd ult., these two varieties have covered themselves with distinction in another direction. Together with single tubers of *Northern Star* and *King Edward VII.* they were sent all the way to Toronto. Upon their arrival they were complimented by the newspapers in "descriptive paragraphs," and their possessor was advised to hand them over to one of the Canadian Government's experimental farms, and many people "were anxious to secure a sprout or an eye." The owner, however, being a shrewd native of Lincolnshire, refused to sell, as he is experimenting with the Potatoes himself. The *Evergood* and the *Northern Star* have also been the winners of several disease-resistance challenges, but, my space being limited, their doings in this respect must here remain unchronicled. Messrs. Carter Page claims that from 1lb. of "Stars" they grew 178lb. of tubers.

One of the most useful of the implements for lifting Potatoes is the rotary digger. There are several types upon the market, but all have the common features of a ploughshare, a rotating wheel which brings the tubers up to the surface, and some sort of catch-screen against or into which the Potatoes are thrown. And some of these implements have the most elaborate arrangement for combining the operations of lifting and gathering, one actually putting the tubers into an ordinary farm cart. There is also a highly ingenious machine for

POTATO EVERGOOD.

were under that weight, the price per pound worked out to nearly £200. Again, it is reported that two tubers of *Eldorado*, which were bought by a *Sleaford* auctioneer (Mr. R. Earl) for £19, have just been resold by him for the astounding sum of £35. These "tates"

remember the two great "blight" years of '46 and '47.

The *Northern Star* was first put upon the market in 1902, and in January, 1903, was selling at 5s. per pound, but so great was the demand that Mr. Findlay raised the price to 7s. 6d. It then rose to 10s., then to 15s., and finally to £1 per pound; and well on in the autumn it continued to command very high prices, and, in spite of the heavy yield of those

\* "Roses and their Culture." By T. W. Sanders. Published by Messrs. Collingridge, Aldersgate Street, London.

† "Fertilisation of Orchids." Published by John Murray, Albermarle Street. Price 2s. 6d.

POTATO ELDORADO.

riddling the "tates" into different sizes, which is accomplished by simply turning a handle. The inventor of this great labour-saver is Mr. John Shore of Owston Ferry, Doncaster.

Perhaps in no part of the country are the farmers such keen business men as those in South Lincolnshire, and they are generally among the first to adopt any new labour-saving machine. Nowadays the large farmer works his head quite as much as does the City merchant, and he is always scheming for the more economical working of his farms, for few are now content with one. No South Lincolnshire farm now goes a-begging—indeed, an almost indecent scramble takes place as soon as the land becomes, or is likely to become, vacant.

Of the younger and larger farmers, Mr. George Caudwell is as enterprising as any. Lately he has taken to hauling large quantities of "tates" to the railway by means of a traction engine built by Messrs. Burrell and Sons, Limited, of Thetford, as being a cheaper form of transit than the use of horses. The load shown in the trucks amounts to thirty tons. Previously four horses were required to pull one farm waggon, and as the station is some miles distant from Mr. Caudwell's farms, relief horses had to be stationed halfway. Thus the horse is being ousted, and the engineer is taking the place of the old-time carter.

Lincolnshire deserves to loom more largely in the horticultural horizon; it is the home of a great industry, and is becoming more so as the years go by. Acres of that county yield great profits.

TOYE VISE.

## MARKET NOTES.

*Roses.*—There is now a more plentiful supply in the market. Flowers of Niphetos are very good. There are also some good Catherine Mermet. Mrs. J. Laing is the best pink seen at present, but Mrs. W. J. Grant is undoubtedly a finer Rose. Red

POTATO NORTHERN STAR.

Roses are now coming in better. On Saturday, 27th ult., there were some General Jacqueminot; the flowers were not large, but bright in colour, and were making good prices. It is surprising how well this old favourite holds its place as a market Rose. There are also a few Maréchal Niel, but

these are not quite first quality, and the colour is hardly deep enough. With a few bright, sunny days we may now expect a considerable increase in the supply of Roses.

*Liliums.*—Messrs. T. Rochford and Sons now have a large supply of longiflorum, also laocifolium and anatum; the two first-named are also to be seen on several other stands. There is a fair demand for these at moderate prices. Lily of the Valley continues plentiful, both in pots and cut; the prices do not vary much. Callas may be bought at very low prices. Tulips are very plentiful, but some of these are of very poor quality, and there are some extra fine to be seen. On Messrs. Low and Co.'s (of Uxbridge) stand were some very fine doubles, crimson, and deep orange yellow. Gardenias have been making good prices. It appears that they are likely to be much in demand the coming season. Carnations are beginning to come in more plentifully, but the best blooms still make good prices.

*Azaleas.*—A good many growers are now bringing in well-flowered Azaleas, Niobe, Flag of Truce, and Deutsche Perle are favourite whites; Apollo is a very fine double scarlet; Simon Mardner, rosy pink; vernaeneana, salmon, with white margin; Mme. Van der Crupsen is very plentiful; it is one of the best to flower early, but it is not quite the best shade of crimson for the market. The best quality Azaleas sell well at good prices, but smaller plants, and any that are not well flowered do not go out so well, and on Saturday there were a good many left on the stands at closing time.

*Genistas.*—These are over plentiful. Several growers are bringing in well-flowered plants, and a good many remained unsold. It will not be until we get warmer weather that there will be much demand for these.

*Marquerites.*—These are also very good now, and several growers are sending them in in large quantities. Cyclamens continue to be plentiful, and have to be sold at low prices to clear out. Erica mooreana and E. fastigiata are good, but the mooreana is not quite so well flowered as we get it some seasons. Acacia Drummondii, A. armata, and others are good, but the cut Mimosa from France, which is now so abundant, affects the sale of these. There are now several distinct sorts coming from France. A few Solanums are still to be seen in the market, but there is no demand for them. Spiraea japonica from several growers, but the cold weather on Saturday made these look unhappy; the early forced plants will not stand much cold. Cinerarias were very good on several stands. Although rather tender these will always be favourites on account of the bright colours.

*Daffodils.*—These are much in favour as pot plants, though on Saturday the supply considerably exceeded the demand. Golden Spur was very fine with several growers. Hyacinths.—The trade for these was very slow on Saturday, and large quantities remained unsold. The supply of Palms, Ferns, and other foliage is in excess of all demands. The very cold weather made trade for all pot plants

POTATO SIM GRAY.

much quieter than it otherwise would have been. Several growers have started bringing in hardy flower roots, and as soon as we get another spell of mild weather Pansies may be expected. It is surprising the large quantities of these sold every season. A. H.

## NURSERY GARDENS.

MESSRS. SUTTON AND SONS'  
PRIMULAS AND CYCLAMENS.

**C**HINESE PRIMULA time is almost over, the Persian Cyclamens, too, are flagging, but one sunny morning recently the large plant houses at Reading were full of colour from both groups, and the sunshine brought out the pure and clear shades of some and the intense depth of others, an object-lesson in the art of hybridisation which must fill every earnest gardener with enthusiasm. An array like this, representing the finest forms created by the firm, is a witness to the skill and perseverance of those who cross and select certain types to bring about some hoped-for colour or habit of growth. The white becomes purer, the rose clearer, and the purple free from magenta by this persistent determination to bring everything that shows a departure from existing types to a certain standard set up as the goal to be reached. Those who enjoyed the Chinese Primulas years ago must rejoice in the present day to find that the hybridist has run off into many byways and raised up a race of free-growing, free-flowering, and, to use the words of the catalogue, "elegant strain" to go hand in hand with the varieties of dwarfier growth and denser flower-spikes. We enjoy both, and when the colours are decided the effect of a large mass is bewildering.

We have heard and read of the older strain of Chinese Primulas, the Giant Pink, White, Crimson, Crimson King (a flower of wonderful colour), Brilliant King, the famous Pearl (still one of the most priceless of the family), the Fern-leaved, and the doubles in various colourings. All these were a brave show a fortnight ago, but we may single out one in particular, as this has been shown and admired greatly at the meetings of the Royal Horticultural Society. It is called The Duchess, and has a special distinctiveness in a zone of rose-carmine on a white ground with the yellow eye in association. It is a remarkable contrast of colours, and the flower faces one as if to say "Look at me," but there is nothing unpleasantly aggressive in this commanding presence. It is a beautiful variety, the individual bloom large, shapely, and supported on a short, strong stem. It should stimulate much interest in the dwarfier Chinese Primulas.

It is not for us to write of the hybrids in course of development. There is no standing still, and as the scientific student knows the most curious and unexpected departures from a normal type occur when flowers are grown on a large scale in particular. Each is carefully set aside for investigation and trial. It is the watchful eye that has created the flower beauty in our nurseries and gardens, and a future generation may revel in things unknown to the gardeners of to-day. Those who care little for the dwarfier Chinese Primulas because there is a certain formality in their growth will be satisfied with what is known as "Stellata" Primulas, which were introduced by Messrs. Sutton to the notice of the public in 1895. This strain has much utility. The plants have a freshness and gaiety that makes the staid beauty of the splendid dwarfier types even more welcome. We want the two groups to enjoy the Chinese Primulas in their fulness. The Stellata race is represented by varieties of many colours. There is the original White Star, which has still a strong hold upon the affections of the indoor gardener, who can gather the flowers for the table and make pretty effects with the dark-stemmed spikes. A variety that we think even more of than this is White Queen Star. It has lost none of the freedom of growth, but there is greater

substance in both leaf and flower, so much so that both may be represented in a house without fear of approaching a repetition. Mont Blanc is another distinct advance, but Ruby Star is the variety to possess for intense colouring. It is as deep as in Crimson King, and is attractive either in the clear light of a winter day or in the evening, and it is well to know the flowers that lose nothing when in the house.

But blue is the colour that seems to fascinate in these houses of flowers. Those who do not know the blue Primula may recall to mind the crude stages of the hardy Primrose before the purer shades were reached, a mingling of ultramarine and magenta, and sufficiently unpleasant to make one wish that the attempt to achieve a blue Primula had proved abortive. This is changed to-day. The flowers are enjoyable, not perhaps the blue of the violet or the gentian, but pure and free from harsh shades of magenta and purple. In the doubles and singles there is the same fresh colouring, and a Cambridge Blue is a companion to Reading Blue, and in Blue Star, one of the Stellata group, there is the contrast with the soft green leaves. We think perfection must have been reached in purifying the blue shades; but Messrs. Sutton would probably say "Certainly not."

Hybridisation is progressive. It is reflected in the Persian Cyclamens, which flower at the same season. The varieties are very beautiful, the whites as pure as driven snow, and the salmon shades unusually clear, and in cherry red we get a bright and attractive flower which is likely to prove most popular in the future. From white to the deep crimson of Vulcan there is a series of colourings without an unpleasant shade. It is the beauty of the flower colouring that appeals perhaps most strongly in the collections of Primulas and Cyclamens at Reading, but with all this the work of improvement and seeking after new varieties continues unabatingly. Some interesting sidelights upon the results of hybridising Primulas were recalled in a paper read by Mr. Bates, F.R.S., at a recent meeting of the Linnæan Society. We hope to publish this.

## OBITUARY.

MR. THOMAS HUNTER.

**M**R. THOMAS HUNTER, proprietor and editor of the *Perthshire Constitutional*, died in Perth on the 24th ult. He took much interest in country affairs, and was the author of a work entitled "Woods, Forests, and Estates of Perthshire," which was awarded the highest honour at the International Forestry Exhibition at Edinburgh in 1884. It has long been acknowledged the standard work on the subject. He was a man of varied abilities and accomplishments, and will be much missed in the city and county.

MR. WILLIAM HERRIES.

MR. WILLIAM HERRIES, who died at 31, Church Street, Maxwelltown, Dumfries, on the 23rd ult., was for long gardener at Lincluden, Dumfries. At the time of his death he was eighty-six years of age, and had retired from active work. He was much respected, and for many years possessed the confidence of his employers at Lincluden, the gardens there being exceedingly well kept.

**The recent gardeners' meeting.**—Kindly permit me to remove the impression that any body of head gardeners, in committee or otherwise, had resolved to take any action whatever. At that meeting the gardeners' dinner committee were asked if, before disbanding, they would act as intermediaries in convening a meeting of gardeners to enable that most estimable member of the fraternity, Mr. Divers, to lay his views on the subject of forming a private gardeners' association before them. That was acceded to, and the meeting, through the kindness of the Horticultural

Club, was held at the Hotel Windsor in December last. There were about twenty persons present. A far more complete discussion of the subject took place then than seems, from the reports furnished, to have taken place at the recent meeting. Ultimately it was agreed that a committee of gardeners—myself as temporary secretary—consisting of eight persons, be formed to either prepare a scheme and rules or bring up a report to an adjourned meeting to be held on February 23. That committee met once, and again the subject was fully discussed. It was then agreed that there was not before them evidence that such an association as was proposed was likely to receive general support, and I was invited to draft a report giving the committee's conclusions. That I did, and Mr. G. Kelf kindly undertook to read it in my enforced absence through illness. It was a document meriting a better reception than it seems to have received. Of the eight members of that committee four were present at the recent meeting, and four, including myself, were absent. The three absent gardeners wrote me letters of regret, because being only gardeners their time was not their own. Thus no pledge was given to support any resolution, the matter being absolutely open for discussion. Neither the dinner committee, which did the work it undertook so well, nor myself have anything further to do with any proposals, whatever they may be.—A. DEAN.

**Highgate Horticultural Society.** The annual exhibition of this society will be held on July 14 next in the grounds of Hillside, Fitzroy Park, Highgate.—W. E. BOYCE, Secretary, 33, *Holmesdale Road, Highgate.*

**Allotment and cottage gardening.** The lecture by Mr. A. Dean on this subject at the meeting of the Royal Horticultural Society on Tuesday next should be an interesting one. This is an important aspect of gardening.

**Shrewsbury summer show.**—Messrs. William Bull and Sons announce that they are offering through the Shropshire Horticultural Society a special prize for new plants, a silver cup value ten guineas and £5 cash, to be awarded to the exhibitor of the best six new plants sent out by this firm. A list of the plants eligible for this competition will be supplied on application to Messrs. William Bull and Sons, new plant, seed, and bulb merchants, King's Road, Chelsea, London, S.W.

**United Horticultural Benefit Society.**—The annual meeting of this society will be held at the Caledonian Hotel, Adelphi Terrace, Strand, on Monday, the 14th inst. at eight o'clock, when Mr. H. J. Wright will take the chair.

**Veitch Memorial Fund.**—At an adjourned meeting of the trustees held on the 23rd ult. it was decided to offer the large silver medal for distinguished service to horticulture to Mr. John Wright, V.M.H., in recognition of his long and persistent efforts to diffuse amongst the industrial classes a practical knowledge of the cultural requirements of the vegetables and fruits most necessary for gardens, and as an author who has written several valuable treatises on subjects relating to horticulture. Also a similar medal to Mr. Thomas Challis of Wilton House Gardens, Salisbury, for his long and many services to gardening, especially in reference to his improved cultivation of hardy fruits.

**Mr. George Field Morris.**—Owing to advancing age Mr. Morris has retired from the firm of Messrs. Protheroe and Morris of 67 and 68, Cheapside, E.C., and Leytonstone, as from December 31 last. Mr. G. F. Morris has been connected with the firm for fifty-eight years, although for the last ten years he has not been actively engaged, having left the entire management to the four other partners, Messrs. H. G. Morris, J. B. Slade, T. A. Morris, and A. E. Protheroe, who will continue the business. We are glad to be able to state that Mr. G. F. Morris is in good health, and we are sure all our readers will wish him many years to enjoy this well-earned retirement. The firm has been established for upwards of seventy years, and the name of the firm will still remain the same.

## SOCIETIES.

### READING GARDENERS' ASSOCIATION.

THERE was a large attendance at a recent fortnightly meeting of the above association, when Mr. Winsor, foreman, Bear Wood Gardens, gave one of those practical demonstrations which have become very popular with the members. On this occasion "Wreath-making" was the subject, and two wreaths were made during the evening. The first was done to show the quickest; the other to illustrate the making when more time is available. The principal flowers used were Arums, Carnations, Lily of the Valley, Roman Hyacinths, Orchids, and Chrysanthemums. A very good discussion followed, in which many useful hints were thrown out by Mr. Powell of Park Place. The only exhibit was some splendidly grown plants of *Primula sinensis*, staged by Mr. T. Butcher, The Gardens, Greenbank, Reading. Eight new members were elected.

#### PROGRAMME OF MEETINGS.

March 7.—"Spring Flowers," by Mr. J. Crook, The Gardens, Forde Abbey, Chard. March 21.—"Fruit Culture," by Mr. W. Barnes, The Gardens, Bear Wood. April 11.—"Present-Day Orchid Culture," by Mr. W. P. Bound, The Gardens, Gattou Park, Reigate. April 25.—"The Decoration of Vases with Flowers," with practical demonstrations, by Mr. T. J. Powell, The Gardens, Park Place, Henley-on-Thames. N.B.—April 25 will be "Hospital" night, when bunches of cut flowers are solicited. These will be sent to the Royal Berkshire Hospital after the meeting. Members are invited to bring specimen plants, &c., to the meetings. Certificates of merit for cultural skill will be awarded during the session to plants, flowers, fruit, and vegetables.

### GLASGOW AND WEST OF SCOTLAND HORTICULTURAL SOCIETY.

THIS society has issued its prize schedule for the flower show to be held in St. Andrew's Hall, Glasgow, on September 7 and 8. The prize list, which is an extensive one, is much the same as in former years, and prizes of considerable value are offered in many cases. A few of the leading classes are referred to now, but the schedule can be obtained on application to the secretary, Mr. Hugh M. Mackie, C.A. (of Mackie and Clark), 55, Bath Street, Glasgow. In the open classes the leading one is that for the best exhibit of fruit, to occupy space 6 feet by 4 feet, not necessarily grown by exhibitor, foliage or small plants allowed for effective staging: First prize, cup, value £5; second prize, plate, value £3; third prize, plate, value £2. In the classes for gardeners and amateurs the leading ones are: Table of plants arranged for effect, 12 feet by 6 feet: First prize £4, second £3, third £2; Collection of twelve dishes of fruit, distinct, not more than two varieties of any sort: First prize, the Malcolm Dunn Memorial Medal in Horticulture, with £2 10s. presented by the trustees; second £2, third £1; Collection of vegetables, containing thirteen varieties (specified): First prize, £3 and the Austin and M'Aslan Challenge Cup (conditions regarding which are on page 8 of schedule); second £2, third £1. As in former years, a noteworthy feature of the schedule is the number of prizes given by donors, and entered in the body of the prize list. The business men of Glasgow give great support to this society, which has had at times severe struggles to hold its own. It is gratifying to observe that last year's accounts show a surplus of £10 14s. 11d.

### SPEKEFIELD GARDENERS' SOCIETY.

THIS society has long been noted for its success in the midst of unfavourable surroundings. In one of the most thickly populated districts of Liverpool, with gas and other works in the immediate vicinity, the amateur and cottager produce many surprising exhibits at their annual show. To increase the knowledge of its members the committee recently arranged for a series of lectures by Mr. John Stony, on "The Principles of Horticulture," which were given in a style suited to the audience, and embraced such items as soils, manures, vegetables, especially Tomatoes and Potatoes, flowers, especially those suitable for their August show, and diseases of plants, their prevention and cure. The information imparted was practical and such as could be followed by those present. Illustrations and specimens did much to bring the matter home to the audience. The attendance was good. The closing lecture proved highly interesting, showing in a marked manner the appreciation of the members. A handsome silver-mounted stick, suitably engraved, was presented to the lecturer.

### IRISH GARDENERS' ASSOCIATION AND BENEVOLENT SOCIETY.

#### ANNUAL REPORT.

NOTWITHSTANDING the many claims on gardeners and others interested in horticulture, this society continues to make steady progress. The most notable event of the past year was the honour conferred on the members of the association by His Most Gracious Majesty the King, who, on his visit to this country, was pleased to accept in person a loyal address of welcome. Four members applied for and received full benefit. Early in the year lectures were delivered in the XL Café, Grafton Street, the first in March, by Mr. P. M. Moran, on "Fruit and Flower Packing for the Market." In the following month (April 7), Mr. F. W. Moore delivered a very instructive lecture on "Orchids," which was illustrated by limelight views. The attendance at both meetings was extremely large. At the monthly meetings papers were read by Mr. Colgan on "Vine Culture"; Mr. A. Campbell, "Horticulture To-day and Twenty-five Years Ago"; and Mr. W. E. Gunn on "Rose Rust." By permission of Lord Howth's agent, Mr. Bullock, the members were afforded special facilities for spending a most enjoyable and instructive afternoon among the Rhododendrons at Howth Castle. The party was accompanied by several young gardeners from the Botanic Gardens, Glasnevin, and during the visit Mr.

F. W. Burbidge delivered an explanatory address, which was highly appreciated. In August a second party journeyed to Carton, the residence of the Duke of Leinster, by kind permission of Lord Frederick Fitzgerald, and on the invitation of Mr. A. Black, who gave his fellow gardeners a most cordial reception, and spared no exertions to make the outing a pleasant one for the visitors. With the object of affording the members, their wives and friends, an opportunity of spending a sociable evening together, a most enjoyable meeting was held in the XL Café on Thursday evening, November 10. Mr. F. W. Burbidge presided, and welcomed the members and their friends. Owing to the enthusiastic manner in which the many friends assisted by giving their time ungrudgingly, the large programme of events was successfully carried out with little expense to the society. The members have every reason to congratulate themselves on the position which their association now holds. Nevertheless, much remains to be accomplished, and it is therefore of the utmost importance that the members individually should lose no opportunity of placing before their friends the benefits and educational advantages which the society affords, and also by using their influence towards increasing the number of subscribers.

### ANCIENT SOCIETY OF YORK FLORISTS.

#### ANNUAL REPORT.

IN submitting the annual report and financial statement for the past year, the committee regret that same is not so satisfactory as they would desire, as they have to chronicle an adverse balance of £9 13s. 11d. on the year's working. At the same time they deem it a most satisfactory conclusion, after taking into consideration the adverse circumstances and bad weather. The number of members who have paid their subscription is 753, amounting to £191 14s., being an increase of £1 6s. on last year. The total receipts have been £627 18s. 9d., and expenditure £637 12s. 8d. The receipts for admission to the Chrysanthemum show were £60 4s. 6d. less than in 1902. During the year the committee have deposited on loan with the York Corporation the sum of £200. This, with the balance of £5 6s. 7d. at the bank in the society's favour, represents the amount of the balance. The committee desire to place on record their high appreciation of the valued and willing services of the president (Alderman Sir J. Sykes Rymer, J.E.) rendered to the society during the year. The committee with much regret have to record the loss of one of its most respected members through the death of Mr. J. C. Millburn, which took place on February 13. A special feature in connexion with the society has been the augmenting of the Dahlia show. This was brought about by a number of the committee securing special prizes of plate and cash £26 3s., to add to those offered by the society at the fourth minor show, with which it was incorporated; and the guarantee given by them of no loss to the funds of the society. During late years there has been a steady increase in the growth of Dahlias, and as the Guildhall has been found inadequate to allow of the proper display of the exhibits, and the light being far from satisfactory, the only suitable available building being the Exhibition, the committee after careful consideration decided to give it a trial. The result was most gratifying to all interested in the venture, though the financial profit was very small. The first show this year is on April 13, the second on May 25, the third on July 20, and the fourth (Dahlia show) on September 8. The Chrysanthemum show is fixed for November 16, 17, and 18.

### CARDIFF GARDENERS' ASSOCIATION.

A MEETING was held at the Grand Hotel on the 23rd ult., when Mr. H. R. Farmer presided over a large muster of members. Mr. J. Mounthey, naturalist and preserver to the Cardiff and other museums, gave a delightful and interesting lecture, entitled "Our Summer Visitors," illustrated with over thirty specimens, such as the swallow, swift, martin, cuckoo, nightingale, nightjar, &c. The lecturer, in passing the specimens round singly, gave a brief history of each one, and explaining at the same time, apart from their songs, their particular value in the garden. He was alive to the fact that they often caused great vexation during the fruit season, and, though the losses were considered great at times, it was a fact that, if there were no birds to keep insect life under, complete destruction of plant life was bound to follow unless fought against by artificial means. A variety of questions were put to the lecturer during a pleasant discussion. The unanimous opinion of the meeting was that the sparrow ought to be exterminated.

The best thanks of the association were accorded Mr. Mounthey for his lecture, which was the first of its kind that had been brought before the members.

### HIGHGATE HORTICULTURAL SOCIETY.

THIS old and distinguished society held its forty-fourth annual meeting in the Highgate Literary and Scientific Institution on Monday evening last, the 29th ult., Mr. E. H. Smithett occupying the chair. There was a good muster of members in attendance. The report was of a most satisfactory character, considering the difficulties that this society labours under. A good exhibition was held last season—distinctly in advance of many of its predecessors—and a better tone and a more lively interest among the practical men in the neighbourhood are now felt in the society's welfare. Special mention was made of the fact that the competition last season was much better than usual, and as a natural consequence the exhibition was far more attractive and interesting than has been the case for some years past. Notwithstanding an unceasing downpour, thanks to the generosity of a few enthusiasts, the society is able to show a respectable balance on the right side. The prospects for the current year are bright enough. Mr. E. H. Smithett, of Hillside, Fitzroy Park, Highgate, has accepted the presidency of the society, and has placed his grounds at their disposal. He is also a most generous donor of special prizes, and more local residents, including the Baroness Burdett-

Countts, have also come forward with the promise of others of a special character. Mr. W. E. Boyce, Holmesdale Road, Highgate, N., is the secretary, and he is working hard to improve the prospects of and aid the society in its usefulness. The show is fixed for Thursday, July 14 next, and the committee are hopeful of eclipsing last year's fine display.

### BRISTOL AND DISTRICT GARDENERS' ASSOCIATION.

A WELL-ATTENDED meeting of this association was held at St. John's Rooms on Thursday, the 25th ult., when Mr. J. Countts, representative of the Exeter gardeners, delivered an exhaustive lecture on "Greenhouse Hard-wooded Plants." Mr. E. Poole, F.R.I.S., occupied the chair, and on behalf of the Bristol gardeners gave Mr. Countts a hearty welcome. His lecture, although the subject was a very wide one, was full of interesting points, and minute details for the cultivation of Ericas, Rhododendrons, Azaleas, Boronias, &c., were carefully given, potting, composts, trimming, and general treatment receiving attention. A fair discussion followed the lecture, and Mr. Countts received the hearty thanks of the Bristol gardeners for his lecture. Prizes for table decoration were awarded to: First, Mr. Thoday, gardener to Mr. N. C. Dobson, and second to Mr. J. T. Curtis, gardener to Mr. W. Howell Davis, a special certificate of merit being recommended for Mrs. A. Hall (gardener, Mr. Ware) for two beautiful pots of Freesias. The next lecture will be held on the 17th inst., when Mr. Myers will lecture on "Ancient and Modern Gardens," with lime-light views, when a large attendance of members and friends is expected.

### KIRKMICHAEL (DUMFRIESHIRE) HORTICULTURAL SOCIETY.

THE annual meeting of this society was held on the 19th ult., Mr. J. Stewart Lyon of Kirkmichael House presiding. After the financial position had been considered, it was agreed to hold the show this year as formerly, the date being arranged as August 6, power being delegated to the committee to alter it if necessary. The office bearers were all re-elected, with the exception that Mr. S. T. Farish, who has made a most efficient treasurer, was relieved of that office at his request, and it was agreed that the secretaries should also act as treasurers. Mr. Farish was appointed vice-president, and Mr. W. Hair added to the committee in the place of Mr. S. Dinwiddie. The secretaries are Mr. A. E. Ryder, Buckwood Lodge, and Mr. J. Shannon, The Gardens, Kirkmichael House.

### READING AND DISTRICT GARDENERS' ASSOCIATION.

THERE was a large attendance of members at the last fortnightly meeting of the above association, when Mr. T. Neve, of Sindlesham House Gardens, Wokingham, introduced the subject of "The Potato in connection with the year 1903." He noted the value of the Potato, the universal failure of the 1903 crop, the different varieties of Potatoes, spraying to prevent disease, and made the following suggestive remedies to prevent disease, viz.: To have an entire change of ground for growing the crop; using manures that are suitable for Potatoes; change of seed; give more thought to the early and second early varieties, and not put so much faith in the later ones; and last, but not least, obtain a Potato with a strong constitution. A very practical discussion followed in which the following took part: The president (Mr. Leonard Sutton), Messrs. Bright, Wilson, Fry, Slyfield, Powell, Judd, Exler, Stanton, Unbridge, Lasham, and Professor Percival, who gave much valuable information on diseases, manures, spraying, &c. A vote of thanks was accorded to Mr. Neve, and also to the various exhibitors, viz., Mr. G. Herridge, who staged Marie Louise Violets; Mr. T. J. Powell, for a basket of young Potatoes, picked from old tubers placed in the dark, chalk arches at Park Place Gardens; Mr. W. Slyfield, for some fine specimens of Up-to-date Potatoes; and to Messrs. Sutton and Sons for a basket of Discovery Potato.

### STONEHAVEN, N.E.

THE annual meeting of this society was held in Stonehaven recently. The report of the secretary and treasurer was of a gratifying character, there being a balance of upwards of £20 at the credit of the society. Office-bearers for the year were elected, these being: Hon. president, Provost Mowat; Hon. vice-presidents, Bailie Ogg and Mr. Booth; president, Mr. G. McLennan; vice-president, Mr. John Ritchie; secretary and treasurer, Mr. William Thomson. The various committees were reappointed and arrangements made for the show, which is to be held at Old Lodge Park, Urie, on Saturday, August 13. Like many other shows, sports are arranged for in connexion with this one, and Highland games will be included among them.

### CHISLEHURST GARDENERS' SOCIETY.

At a meeting of this society, held on the 23rd ult. in the Schoolroom, Chislehurst, there was a large gathering, and those present were well repaid for the trouble they had taken in turning out by the admirable lecture in store for them. The initial business over the chairman (Mr. Lyne) at once introduced the lecturer, Mr. Henry Canby, V.M.H., of "The Home of Flowers," Swanley, whose subject was "Fruit, and How to Eat It." In opening his remarks, he said that, the subject being new, it would require consideration and time to see its necessity and value. He had heard a great deal about propagation, cultivation, and kindred subjects appertaining to gardening, but very little about making the best of the crops they grew. "Good health is better than riches," and in his opinion the food had come when it behoved each one to look after his health. One way of doing that was to bring fruit more and more into the daily food. Being a practical gardener himself, he felt it his bounden duty to tell the community what he thought; in fact, he was certain fruit was the best food to eat.

# THE GARDEN

No. 1686.—VOL. LXV.]

[MARCH 12, 1904.

## SPRING AND ITS WORK.

**T**HERE has been enough in the past season to make even stout hearts despond as to matters horticultural, and the opening weeks of 1904 so far have not been very reassuring. We have much sympathy with all who have suffered, first by frost and later by flood, during the year gone by. But a new spring is at hand, and it behoves us all to lay aside faint-heartedness and buckle to with the will and the courage that is bound in the long run to tide us over every difficulty. We are ready enough, we British, to do and to dare nobly on an emergency, or for a forlorn hope, but in reality it very often needs more pluck to face the daily disappointments, and to hope against hope in matters of everyday life. The storm passes nevertheless, but the bow remains in the cloud, and seed time and harvest never have failed and never shall fail, except through the idleness and ineptitude of human kind. With the return of spring we must needs take a more cheerful outlook. The tide of life is rising once more after its long ebb, the song of birds is heard in the land, the colour begins to blush in the distant tree tops, we can see the buds near at hand visibly swelling. The healthy instinct and energy of work take possession of us, and how much there is to be done! Out of doors many days have been lost through the streaming rains, but we have let the weather hold us too long in its grip. Much can be done in spite of it, and, after all, things are seldom so adverse as they seem.

One main factor in success in gardening is to be beforehand. Better by far, in most things cultural, to be a few days too early rather than a week too late. "That's a doctrine that won't hold water," some grumbler will say. "Those Ashleaves I set last year, on purpose to have them extra early, got caught by the frost and never came in till a fortnight later than some that were planted a month after them." That may be very true, but possibly a little more forethought—a few hoops and some mats to cover them for a night or two, or even a little dry Fern shaken down over the rows might have saved the disaster. We very often accuse the untowardness of circumstances when we ought to lay the blame on the last persons we are apt to think of—ourselves.

The right time, of course, is the best time, and in all garden work it is easy enough to know it even to a day, but of the two alternatives we maintain that it is better to be a few

days too soon than to be too late. Too late! What a bitter cry that is, when all might have been well but for our own short-sightedness. How unpardonable, when we must needs write it in the dust of our own neglect. The trenching that should be done in winter put off indefinitely, when an hour or two seized, as opportunity and a clear sky offered, might have got it all done in good time for the sowing which must now be delayed; the seedlings allowed to run up in the seed-pan, when a single half hour's work would have seen them potted off, to grow apace for their next shift; the cuttings left pot-bound to get stunted for good and all for want of a timely move. There are few, indeed, who have not to blame themselves, some time or other, for putting aside some unwelcome job in favour of one more light and pleasant, though the one was pressing and the other of little consequence.

Nothing repays one for one's trouble more fully than garden work done when it ought to be done. Whether we are professional gardeners or mere amateurs it matters not, the principle holds good. How many instances recur to mind in every day practice. Take a case in point. The right time comes to take cuttings of some plant or shrub one wishes to increase.

Last year, perhaps, the opportunity was allowed to slip, and with that lash of conscience to drive one on, the thing is done. It takes just ten minutes to cut, make, and put in a potful, and to place them in the frame or whatever position is the most suitable at the moment. The pot is cared for with the rest of its neighbours, and weeks after one comes by without having, perhaps, in the interim bestowed much individual care or thought upon it, and, behold! the cuttings have rooted and are growing away strongly. Many a plant on our greenhouse shelves at the present moment is the result of the work of a few spare minutes.

Now and then it may happen that we should have done better to wait awhile—it is easy enough to be wise after the event—but in our uncertain climate we are bound to take some risks. The chances are that nine times out of ten we gain more than we lose by being well to the fore. Then let us plant and sow and prune our Roses, and carry on all our timely garden operations with cheerful hearts, doing our best and letting no opportunity slip for lack of force and perseverance. We will hope, moreover, for a more prosperous season, with sunshine and shower just when both are most

wanted. Yet let us take it bravely as it comes, believing that the all-wise Providence, who visits the earth and blesses it, will also in due season bless the increase thereof.

## PLANTING TREES AND SHRUBS IN MARCH.

**P**ROVIDED the weather is open and the ground is in working order the planting of trees and shrubs can be carried on in March. There are, however, a few subjects which are better left until April, viz., Hollies, Magnolias, the Tulip Tree, and any rare or choice plants that require special attention. The two great points to bear in mind in planting trees and shrubs, especially evergreens, are, firstly, the amount of warmth and moisture in the ground; and, secondly, the state of the weather for a week or two after planting. Usually the ground is at its coldest in the beginning of March, but about the middle of the month it begins to get warmer, and, being then in a moist condition as well, plants begin to make fresh roots freely. The weather after planting is also an important factor in determining the future of fresh-planted subjects. Thus, if the cold, drying, easterly winds so often experienced in an English spring should set in, then plants will suffer badly, as they get dried up before they have made sufficient new roots to supply the amount of moisture they require. On the other hand, a fortnight of moist weather—even if cold—after planting will establish them sufficiently to withstand almost any weather afterwards.

Spring planting of most hardy trees and shrubs is best done as early as possible, especially with the commoner and hardier kinds, as, though the ground may be cold, yet the plants get settled down and are ready to make a start as soon as the ground is a little warmer. There is also more moisture in the air during the early spring than there is later on, and therefore plants do not suffer from drying winds, which, after all, are the greatest enemy to newly-planted trees and shrubs.

At the moment of writing the weather seems to have set in with spring-like warmth and sunnier skies. These conditions will help on the planting. The ground will soon get drier, and the sowing of seeds proceed more easily than has been possible of late. It is to be hoped the present pleasant weather will continue for many weeks.

*Bagshot, Surrey.*

J. CLARK.

## NOTES OF THE WEEK.

## FORTHCOMING EVENTS.

March 16. — Royal Botanic Society's Flower Show.

March 22. — Royal Horticultural Society's Drill Hall Meeting.

April 5. — Royal Horticultural Society's Drill Hall Meeting.

April 8. — Truro Daffodil Show (two days).

April 12. — Brighton Horticultural Show (two days).

**History of the Royal Horticultural Society.**—We have received "A Short Historical Sketch of the Royal Horticultural Society," by Sir Trevor Lawrence, Bart., V.M.H., the president. Sir Trevor first outlines the formation of the society in 1804, the granting of the Royal Charter in 1809, and passes on to mention the vicissitudes through which the society passed when its home was at South Kensington, the famous Chiswick shows, the plant collectors sent out by the society, and, finally, the more recent history of the society, which is a record of progress.

**Horticultural Club.**—A delightful evening was spent on Tuesday last at the Hotel Windsor, when a lecture was given by the Rev. Professor Henslow on "The Use and Abuse of Botanisng." There was a large attendance. A full report will be given next week.

**Royal Botanic Society: Horticultural Exhibition.**—From June 6 to June 11 there will be held in the gardens of the Royal Botanic Society, Regent's Park, a grand horticultural exhibition. Conferences and lectures on gardening will be held during the exhibition. Gold, silver, and bronze medals and diplomas will be awarded. The exhibits will be very comprehensive, comprising all plants and horticultural sundries, and there will be also botanical, colonial, and art displays. Applications for space must be made on the official form and sent to the offices of the society, Botanic Gardens, Regent's Park, London, N.W., before May 1.

**Mr. E. W. Gilbert.**—Amongst the honours conferred by his Majesty the German Emperor, on the occasion of his birthday, we notice that Mr. E. W. Gilbert received the High Order of the House of Hohenzollern. Mr. Gilbert was formerly in the gardens of the Duke of Sutherland at Trentham, and also in the gardens of her late Majesty at Frogmore.

**Primulas for waterside planting.** Mr. D. S. Fish, in his interesting notes on the above on page 93, states that seed of *Primula sikkimensis*, after being dried, takes a year to germinate. However, that is not always the case, as we sowed it here on January 18, and the seedlings were pushing through the soil by the end of the same month.—G. W. KERR, *Baker's Old Hall Nurseries, Wolverhampton.*

**The garden city movement in Scotland.**—A meeting to promote the garden city movement in Scotland was held in the Hall of the Society of Arts, Edinburgh, on the 29th ult. The chair was occupied by Principal Hodgson, and a large number of ladies and gentlemen attended. After a sympathetic speech by the chairman an address was given by Mr. Thomas Adams, Secretary of the Garden City Association, London, regarding the objects of their association and its manner of working. The proposal of a similar one for Scotland had, he stated, been made chiefly on account of the new naval base at Rosyth, where it was estimated about 30,000 people would be settled in the course of a few years, and it was considered that every opportunity should be taken to have this new town built on scientific principles. It was thought that a Scottish Association would be able to bring more influence to bear with the Government, in order to induce them to lay out the town on the garden city principle. Mr. Adams moved that a Garden City Association be formed in Scotland, and that an executive committee be appointed. This was seconded by Mr. H. F. Kerr, architect, and agreed to. An in-

fluenial committee was appointed. In the evening Mr. Adams addressed a crowded meeting in the Queen's Hall, Edinburgh, under the auspices of the Edinburgh Citizens' and Ratepayers' Union, Sir Colin G. Macrae, president, being in the chair. Sir Colin Macrae, in the course of his introductory speech, expressed sympathy with the objects of the Garden City Association, but stated that the union was not to be held as committing itself to everything which was said. Mr. Adams then proceeded with his lecture, which was of an interesting character. Canon Rawnsley moved a resolution in support of the movement, and it was seconded by Dr. Clouston, and unanimously agreed to. The Rev. Dr. Glasse moved a vote of thanks to the speakers, and a similar compliment to the chairman was moved by Mr. J. W. M'Hattie, superintendent of Edinburgh City Parks. — S. ARNOTT.

**Proposed Gardeners' Association.** At a meeting of the provisional committee, held on March 8, it was decided to arrange for a public meeting of gardeners to be held in London on the second day of the Temple show (June 1), when a scheme for a National Association of Professional Gardeners will be submitted for approval. It was also decided to ask for donations to enable the committee to print, for circulation all over the country, a pamphlet setting forth the main objects for which the association is to be formed, and the advantages of co-operation and registration. Donations should be sent to the secretary, *pro tem.*, W. Watson, Descanso House, Kew Road, Kew.

**Gardening at Earl's Court Exhibition.**—It is always satisfactory to note the gardening at this popular place of resort. Irrespective of this, encouragement has been given by the enterprising directors there during the last few years to the exhibitions of some of our special societies—the National Dahlia Union and the National Sweet Pea Society—privileges which are, I believe, to be accorded this season. Special efforts are being made at Earl's Court this year to vary and improve the gardens surrounding the exhibition, which will be devoted this season to a comprehensive display of Italian art. Messrs. G. W. Bellgrove and Co., the well-known decorative florists, &c., of Fulham Palace Road, Hammersmith, who did a portion of the garden work last season, have this year been entrusted with the whole undertaking. Palms, some 15 feet to 20 feet in height, will, amongst others, form some noble material for effect, as will *Dracænas*, *Grevilleas*, *Ficus*, and other suitable sub-tropical subjects. In the western gardens an Italian garden is being formed, in whose vicinity will be—appropriately—a rich display of Italian statuary. Last year a praiseworthy attempt was made to give visitors a glimpse of Old English gardening.—Quo.

**Effects of the weather on the nursery trade.**—The wet weather of the past twelve months has been the cause of a great deal of loss to farmers and agriculturists generally, but its effect on the outdoor nursery trade has also been a very bad one. Not only has it caused loss through the swamping of low-lying and heavy lands, and the consequent ill-effects on the stock growing thereon, but it has also caused much less planting throughout the country than would have been the case if this winter had been a normal one. Taken altogether, the autumn trade was fairly good, and the prospect was promising. The open weather, with a fair rainfall, were inducements to planting, and the majority of outdoor nurseries were comfortably busy, though not hard pressed. The torrential rains of January and early February, however, seem to have stopped all planting, and the effect has been felt by practically every nursery in the country. About five inches of rain have fallen since January 1. As a rule, an open February—that is, one free from hard frost and snow—is one of the best months in the year for the nursery trade, but this year it was a very bad month generally, even though it contained an extra day. The heavy rainfall, followed by a spell of wintry weather, has made nearly all intending planters fight shy of buying plants, to have them

practically swamped directly afterwards, as there is no guarantee that when the frost and snow disappear we shall not have a return of the heavy rains we have become accustomed to. In many low-lying places, where much planting was done in the early autumn, the plants have suffered through standing in water for the greater part of the winter. In ordinary seasons the autumn is the best time for planting, as the ground is moderately warm, and the plants will make fresh roots in a month or so; but this season they were subjected to heavy cold rains soon after being planted, and, with a lower ground temperature, they have made no fresh roots, being really in the same, or even worse, condition than when they were planted. It is to be hoped that a spell of drier weather will set in shortly to gladden the hearts of nurserymen generally, as the present season has been bad enough to make even the most hopeful feel rather despondent.

**The Departmental Committee on Fruit Culture** appointed by Lord Onslow held sittings on Wednesday and Thursday, the 24th and 25th ult. The following members were present: Mr. Boscawen, M.P. (chairman), Colonel Long, M.P., Mr. C. W. Radcliffe-Cooke, Mr. Hodge, Mr. Monro, Dr. Somerville, Mr. P. Spencer Pickering, the Rev. W. Wilks, and Mr. Ernest Garusey (secretary). Evidence on behalf of the Board of Agriculture and Fisheries was given by Mr. Rew, of the Statistical Department, Mr. Brooke-Hunt, of the Educational Department, and Sir W. T. Thiselton-Dyer, K.C.M.G., Director of the Royal Gardens, Kew. Evidence on horticultural instructors for county councils was given by Mr. Luckhurst (Derby), Mr. Goaring (Sussex), and Mr. Ettle (Somerset).

**National Amateur Gardeners' Association report.**—The report for 1903 of this institution, together with syllabus of lectures and list of special prizes for 1904, has just been issued, and is most interesting reading. For the small annual subscription (5s.) of its members it is really astonishing what the executive are able to accomplish. Twelve meetings were held last year, and on ten occasions lectures were given by many of the leading horticultural authorities on subjects with which they are specially identified. Several of the lectures were illustrated by lantern views, which added considerably to the interest of such meetings. From March until November the monthly exhibitions always have something in them to interest and please, serving the purpose of educating the inexperienced amateur. Visits to gardens and other places of horticultural interest were organised last season. The conversazione and exhibition in July last was pronounced a great success, the exhibition on this occasion being one of the very best efforts ever inaugurated by the association. The library continues to provide useful knowledge to those who find time to read. The collection has grown during the year. Financially, the association is in a most satisfactory condition. Great care is observed in the management of its affairs that money is not wasted, and as a consequence there is a good balance on the right side of assets over liabilities. The meetings are held on the first Tuesday in each month, at seven o'clock in the evening, at Winchester House, Old Broad Street, London, E.C., this being a good central position and a meeting-place well known throughout the country. The lectures provided for are the following: April 12, "Plant Propagation," by Mr. A. T. Hemsley. May 3, "An Hour with the Daffodil," by Mr. Arthur R. Goodwin, F.R.H.S. June 7, "Orchids," by Mr. E. F. Wicks, F.R.H.S. July 5, conversazione. August 9, "Hardy Perennials," by Mr. E. H. Jenkins, F.R.H.S. September 6, "Carnations," by Mr. S. Hillman. October 4, "Early-flowering Chrysanthemums," by Mr. D. B. Crane, F.R.H.S. November 1, "Alpine Plants," by Mr. Hemsley (Messrs. J. Cheal and Sons). December 6, "Manures and their Uses," by Mr. H. F. Moore. January 3, 1905, presidential address, by Mr. T. W. Sanders, F.L.S. The foregoing clearly indicates a useful year's work, and serves to prove how much is being done by amateur gardeners in an unostentatious way.—C.

**New schools of forestry.**—Lord Onslow, President of the Board of Agriculture, has stated that he is going to start two schools of forestry with the view of training men as woodmen and giving instruction to young men who intend to be land agents. Lord Powis has promised land in Wales for one school.

**Lichens.**—At a meeting of the Edinburgh Field Naturalists' and Microscopical Society, held in Edinburgh on the 24th ult., a paper on "Lichens" was contributed by Mr. James M'Andrew, who has devoted many years to the study of such subjects, and who, when resident in Galloway, was a recognised authority on the botany of the province. Mr. M'Andrew's paper was an excellent one. He was warmly thanked for the paper.

**Aged Roses.**—Some years ago I noticed, either in *THE GARDEN* or some other horticultural journal, that there was at Keevil Manor, Wiltshire, a bed of the old Cabbage Rose, which the owner, Sir J. Wallington, could vouch for as being in the possession of his family for eighty years. It would be extremely interesting if the readers of *THE GARDEN* could give similar instances of old age concerning any special Rose plants in their possession. There is an erroneous opinion that standard Roses are very short lived, but I imagine we should be surprised if the age could be given of some old specimens to be found in the gardens of England, and even in the humble cottage plot.—**PHILOMEL.**

**New botanical laboratory at Cambridge.**—The opening of the new university buildings at Cambridge by the King on the 1st inst. marks another stage in the growth of the university to meet its growing needs, though up to the present the needs have kept well in advance of the growth. These new buildings include a new law school and library, a new botanical laboratory, a new medical school, and a new geological museum. They stand in the heart of Cambridge, on a site that was formerly part of the grounds of Downing College. It will be some time before they are all completed.

**Fruit growing in Scotland.**—Mr. Hodge, Blairgowrie, the Scottish representative of the departmental committee on fruit culture, met with a number of fruit growers and others interested in the subject belonging to the Edinburgh district in Edinburgh on the 23rd ult. The attendance was highly representative of market growers, private gardeners, and nurserymen. Mr. Methven presided. Mr. Hodge explained the objects of the meeting, and asked those present to express their views, which they did pretty fully; the opinions being generally to the effect that there were great capabilities in the district for extension of fruit culture. The difficulties to be encountered were fully dealt with, and the various speakers were afterwards heartily thanked by Mr. Hodge for their valuable expressions of opinion. Mr. Hodge also gave a large amount of interesting information about fruit growing at Blairgowrie. Mr. Sinclair, Prestonkirk, was selected to give evidence on behalf of the Edinburgh district before the committee.

**Lilies in California.**—I had an experience in the culture of Lilies last year which will, I think, be of interest to your readers. I planted a considerable number of the Sierran form of *Lilium washingtonianum* and of *Humboldtii* var. *magnificum* in my garden at The Terraces on a very gravelly slope. As the spring was a dry one I had a ditch dug above them and irrigated at intervals until midsummer. The water percolated to a depth of 1 foot to 2 feet, this subirrigating them. In both root growth and bloom the results were unusual. *L. washingtonianum* is very impatient of surface moisture. This experience reminded me of a lot of this Lily that I noticed at perhaps 7,000 feet in the Northern Sierras some years ago. It was midsummer, but quite a bank of snow above them was melting and percolating, so as to keep the sandy *débris* that they grew in wet. They grew out of low underbrush and were in full bloom at the time. I am inclined to think that many Lilies are pleased to grow in very loose, well-drained soil, but with abundant moisture within reach of their roots. I had *L. Henryii* for the first

time last year. It came late and a little dry, and I gave the bulbs a variety of situations. Nearly all flowered, and I was pleased with the flowers; but if the lax, rather limp habit of the stem is characteristic I do not like it. A Lily should be able to stand alone. My bulbs increased very much in size, and in some soils there was a phenomenal increase of bulblets along the stem below the ground. The Burbank Parryii × *Pardalinum* hybrid Lilies vary considerably in propagating qualities. Some of the pure yellow-flowered forms propagate very slowly from scales, but several have increased rapidly. Strangely enough, several which show the *Pardalinum* blood strongly increase the most rapidly. They are fragrant, but the flowers are not up to standard. I planted some *Gladiolus* in the open last August, and at Christmas picked a bouquet of very good stems. At the same time I had *Narcissus*, *Soliel d'Or*, *Grand Monarque*, and *Paper White* in the open. My first flowers of *Narcissus Henry Irving* and *Princeps* came recently, as well as a few *Tulips Proserpine*.—**CARL PURDY, Uriah.**

**A Note from California.**—The winter has continued to be a remarkably open one in Northern and Central California. The rainfall has not been heavy, but has been well distributed, and in thirty-five years' experience here I have never seen a winter with clearer and brighter days. The temperature has not at any time been low, and everything is unusually promising at this date. In the South Central and Southern portion of the state it has been disastrously dry. Up to this time Los Angeles has not had rain enough to start the grass, while farther south it can be said that they have had none. At the present time their larger horticultural and agricultural interests are little harmed, because they depend upon irrigation; but cattle and other grazing animals are dying of starvation in great numbers, and with little hope of saving any. Unless the fall of snow is very heavy in their higher mountains from this on they will have a short supply of water for irrigation. A feature in the agricultural situation here is the large purchases and shipments of hay to the Orient for the Japanese and Russian Armies. As our own supply of last year's hay was short, it is a disturbing feature.—**CARL PURDY, Uriah.**

**Heather and Snowdrops.**—As some correspondents have recently mentioned in *THE GARDEN*, pleasing combinations of winter-flowering plants are sufficiently rare to make it worth while to place on record any that may come under one's notice. In addition to those already mentioned of the association of *Jasminum nudiflorum* with *Ivy* and *Cotoneaster*, I should like to draw attention to one that I saw recently, and which seemed to me to be the most attractive mingling of winter flowers I yet had met with. It is so simple that I wondered it has not been thought of and practised long ago; perhaps it has, but I never remember to have seen it before.

The plants used were *Erica cinerea* and *Snowdrops*. They are planted in large beds in the terrace flower garden at Windsor Castle, upon a slope facing north. Looking down upon them as one is able to from the walk above the orangery they are a delightful feature in a garden, where at the present time there is nothing else in flower to relieve the monotony of evergreen shrubs and desolate borders. The Heaths have well filled the beds, and in themselves make a bright and cheering display, but when peeping through the masses of reddish Heath flowers

one sees the pure white drooping bells of the *Snowdrop*, then the picture is indeed a pretty one. The *Snowdrops* are not dotted here and there, but there is an abundance of them; they are all over the beds, and by their numbers effectually do away with any danger of spottiness in the bed; had this been the case the effect would have been such as to make the absence of the *Snowdrops* more desirable than their presence. Happily, however, this is not the case, the bulbs were planted with a proper knowledge of their uses, and the result is a charming association of winter flowers.—**A. P. H.**

**English Potatoes.**—It will be interesting news to those who have the Potato so much at heart to know that its cultivation is declining. In 1903 the Potato area was less by 10,000 acres than 1902. This is a decrease of 60,000 tons, or 1,200,000 bags.

**New Potato Sutton's Favourite.**—When so much is being written about some of the new Potatoes and their immense superiority over others, one is diffident in bringing any new sort forward that may appear less known than its merits deserve. For two seasons I have grown *Favourite*, and though last year was so unfavourable it was surprising to find the crop so good; I am sure that none of the new Potatoes that are so costly at the present moment will beat *Favourite*. It is one of the best in flavour; and this should be the chief consideration, and then cropping. With regard to the latter I was delighted with it. There was a very heavy crop, the tubers being of good shape, with scarcely any small ones; the skin is smooth, and there is an absence of deep eyes, so that there is no waste. The flavour is excellent. There was no disease whatever, and this was more noticeable as the seed was home-grown. Other varieties a short distance away were badly affected. The tubers also keep well. At this date—the end of February—they are in splendid condition, being firm and quite sound. For many years the *Windsor Castle* has been our favourite midseason Potato, but *Favourite* will now take its place, as it crops heavier.—**G. WYTHES.**

## NOTES ON HARDY PLANTS

### CYCLAMEN IBERICUM.

**B** OISSIER, in his "Flora Orientalis," makes the Iberian *Cyclamen* a variety of *C. Coum*, and it may well be considered a geographical form of that species. The corm, however, is larger, and it is more floriferous than that species. It also comes into flower earlier, and while the leaves of the typical *C. Coum* are of an uniform dark green, those of this plant are distinctly zoned with white. The flowers of the

CYCLAMEN IBERICUM IN THE HARDY ALPINE HOUSE AT KEW.

typical form are bright red, with a dark purple spot at the base of the petals. From this colour to white there is every gradation of shade in the cultivated forms. It is found growing in mountain woods in the Caucasus and Northern Persia at an elevation of 2,000 feet, and is quite hardy in this country, but is apparently more at home in the extreme southern counties. Here among Ferns and round about trees where the grass is thin it spreads rapidly, producing its flowers in abundance in the early months of the year. For cultivation in pans, as shown in the accompanying photograph, it is better than *C. Coum*. Three corms are sufficient for each 7-inch pan. This should be well drained, and the soil should be loam, with sand and leaf-soil added. Provided the drainage is perfect they may remain undisturbed in the same pans for two or three years with a little top-dressing annually. After flowering they should be plunged in ashes and fully exposed to the sun to ripen the corms thoroughly, removing them to a cold frame for the winter. Under this treatment they flower profusely at the beginning of February. Plants grown as *C. Atkinsi* are evidently forms of this species.

### COLCHICUM CROCIFLORUM.

This charming little plant looks so much like a *Crocus* at the first glance that the name given to

COLCHICUM CROCIFLORUM IN THE HARDY ALPINE HOUSE AT KEW.

it is an excellent one. The flower, however, possesses entirely the *Colchicum* type of structure in all its organs. It is quite different in marking and colouration from all the other species in cultivation, having a distinct character of its own. While we have lilac, with every shade of intermediate gradation to pure white in *C. autumnale*, *C. arenarium*, and *C. montanum*, in the present species the segments have a white groundwork, down the back of each of which run various markings, which extend a little way down the tube of the flower. In some forms the markings consist of five purple lines, others have only one broad or narrow line, while others are suffused with pale lilac all over the back of the segment. Produced six to seven from each corm, the bright green shining leaves are linear, with obtuse points. They are borne at the same time as the flowers, but do not attain their full size till some time after the flowering season is over. The number of flowers produced from each corm varies from four to six, and they have a tube about 3 inches in length. This species was first found by Sewerzow in Turkestan, and since by Dr. A. Regel in the Alatan mountains. The latter sent it to Kew, where it flowered in January, 1883. Although introduced so long ago, it is still a rare plant in gardens, not increasing so readily as many of the other species of *Colchicum*.

The name *crociflorum* has been applied to two other plants belonging to this genus, one a form of *C. autumnale* and the other a form of *C. montanum*.  
Kew. W. IRVING.

### ANEMONE HEPATICA TORCH.

This bright *Hepatica* was the first of all to bloom with me this year, and it did its best to brighten a somewhat gloomy time in the garden, caused by so much rain and so little sun. It is not yet in commerce, but is one raised by Mr. James Allen, who, many will be sorry to know, is now in very poor health, and unable to go about among his favourite flowers. It is of the type of the common *Hepatica*, but with larger and brighter flowers than the best of the red forms in ordinary cultivation. The colour is considerably brighter than what we call the red *Hepatica*, but which is, in reality, better described by some of the old writers as peach-coloured. One may raise many seedlings without being so fortunate as to secure one like this. It is quite distinct from such varieties as *A. (Hepatica) splendens*, and its flowers are as large as those of the *angulosa* section of *Hepaticas*.  
S. ARNOTT.

### GALANTHUS PLICATUS FRASERI.

It is well known to many Snowdrop growers that *Galanthus plicatus* (the Crimean Snowdrop) has an unaccountable tendency to die off and disappear. This is not attributable to the dreaded Snowdrop disease (*Botrytis galanthina*), but to some other cause. This is, to say the least of it, disappointing, for despite its rather small flowers in proportion to its foliage, *G. plicatus* is a handsome Snowdrop. It is not generally known, however, that there is a superior form of *G. plicatus* which appears to be much more permanent than the typical form, and which is also finer in other respects, having larger leaves and finer flowers. It was originally found in the garden of Mr. P. Neill-Fraser of Rockville, Edinburgh, and was selected by Mr. W. B. Boyd. It is considerably superior to *G. plicatus* as we commonly meet with it, and, while from time to time I have lost clumps of the type in my own garden, I find *G. p. Fraseri* thrive and increase. Its ornamental leaves have the reduplication of the type, but the flowers are larger, and thus more in keeping with the fine leaves.  
S. ARNOTT.

## ANNUALS FOR THE GARDEN.

If one were to remark that as a class both tender and hardy annuals are generally neglected, many would receive the statement with derision and not a few others challenge its accuracy. It is not absolute neglect so much, perhaps, as indifference. In all probability in this as in other matters both the garden and the plant suffer from what might be aptly called a plague of cheapness. Doubtless, too, this cheapness is in one sense directly responsible for the lack of display of beauty and of profuse floriferousness that so frequently characterises the growth and flowering in our gardens of many of the

best of annual flowers. And so long as the plague may last it will be of little use to insist that "not more than one dozen seeds must be sown," when the packet just opened may contain several hundreds. Yet the value of a single self-sown seed, whether of *Nemophila* or *Mignonette*, will be more than a match, whether in early or late flowering, to say nothing of the intervening display, for fifty or 100 seeds as ordinarily sown in that most offensive small circular patch little more than a dinner-plate in size. At this moment it is little good talking or writing about the value of autumn-sown seeds. Yet I have a clear recollection of October-sown seed of *Nemophila insignis* giving early and indescribably rich patches of colour month and month, and again of the same plant from a solitary seed producing a carpet of the richest blue nearly 4 feet across. How many hundreds of flowers such a plant would produce I will not attempt to speculate, but it must be enormous. Not only so, for all the early summer flowers from such a plant are infinitely improved in both colour and size compared with the little circular patch into which a whole packet of seed was emptied, not sown. And what is true of one kind is equally true of many, and the remedy is in the hands of everyone who attempts to sow seeds.

To sow thinly at the proper time is advice of long standing, and is too often disregarded. A sure remedy against overcrowding of the seedlings is to sow thinly and prick them off, and as many good annuals object to transplanting to sow a seed or two in a pot and transfer bodily to its destined place. In this way a dozen or fifty plants of *Mignonette* or *Nemophila* may give surprising results with no more labour, perhaps, than that entailed by the ordinary sowing and "timely thinning."

The same thing may be done with the *Stock*, and in this case assist in modifying to some extent the heavy loss that transplanting often entails. The single pot system may with advantage be adopted for the beautiful *Sweet Sultans* as for the very popular *Sweet Peas*. Thus may the ill effects we now see be greatly reduced by two simple methods—viz., sowing in small pots or pricking the seedlings off before planting them in their permanent places. In conjunction with the foregoing early sowing is most desirable, and in some instances the highest cultivation.

In this connexion we may perhaps mention the *Balsam* or *Zinnia*, or both, as subjects seen rarely in good condition in the open. The pot-grown examples of the first only feebly represent the vigour or the boldness or beauty of the plant when grown unchecked. It is much the same with *Zinnias*, and these generally are poorly grown. To some extent this is due to a check in the early stages, and when this occurs the *Zinnia* rarely recovers. It is a vigorous plant, and one for which the highest cultivation is well repaid. In the same category we may place the *Amaranthus* and *Celosia*, both highly desirable for large beds or the boldest groups or masses, and now and again appearing as a groundwork to the well-known *Humea elegans*.

*Petunia verbena*, *Phlox Drummondii*, and *Ageratum* are others that well repay for liberal care. In all of these more or less tender kinds the systematic pricking off of the seedlings will naturally receive attention, and this, with quick growing after, will be very beneficial.

I have not as yet mentioned the endless beauty and variety found in the *Aster* family—a family, by the way, almost exempt from the "plague" to which I have earlier referred. It may not be generally known how much these

plants appreciate a dressing of old mortar rubbish with the soil, and especially so in heavy ground. Where this is not available a dressing of lime should be given the land quite early in the season before planting.

The Poppy is also sure to receive attention, and it is well worthy of it. But here again comes that insufficient appreciation of large groups with ample space for plant development duly considered. For example, what splendid openings there are for such as these or the Cornflower in the forefront of many a shrubbery border, where the leafy soil will support them to the full in the time of flowering. The sloping bank, too, as it stretches away in the distance from the terrace lawn or garden or the woodland may be beautified by a little thought and a few seeds of some such plants. And in the borders where openings are sure to occur will be found room for Gaillardia, Helichrysum, Acroclinium, Rhodanthe, Candytuft, Chrysanthemum coronarium, and other kinds, Larkspur, Lupin, the elegant Gypsophila or curious Nigella, Salpiglossis, Dianthus, to say nothing of those Californian worthies, Phacelia, and others far too numerous to give in detail. Then there are bolder things, as Wigandia, Ricinus, Maize, and draping or climbing plants, as Convolvulus, Tropæolum, and Lophospermum, not omitting the elegant grasses that possess a characteristic beauty. But whatever may be used, there should be only one object—viz., to present the best possible picture that each plant is capable of. In other words, let it so be done that the importance of these cheaply-obtained annual flowers may be obvious to all at a glance, and be found worthy of more frequent imitation.

Hampton Hill.

E. H. JENKINS.

## THE ROSE GARDEN.

### BEDDING ROSES OF FREE GROWTH.

**A**RE we right in requiring that our bedding Roses should be of compact growth? We condemn the flat, unnatural style of exhibiting decorative Roses, yet there seems to be a desire to have the bedding kinds made to pattern. I must confess to a partiality for a mass of colour, but this does not debar me from welcoming some irregular growths to relieve the formality. Take, for instance, that popular Rose, W. A. Richardson. If grown in bush form it will produce a glorious mass of blossom, but its climbing or extra vigorous nature will assert itself, and consequently there are many growths darting up here and there.

I consider a large bed of Gloire de Dijon when well grown and some of the growths bent over to be one of the prettiest features in the rosery, and there are other sorts quite as useful and beautiful. Just to name a few, in addition to those already mentioned, there are: Alister Stella Gray, which is very beautiful as a bedder, and so free and perpetual, too, its pretty clusters of nankeen yellow buds and blossoms a dream of beauty. Bardou Job and Gloire des Rosomanes are two large-flowered single and semi-double Roses of much merit, not beautiful and fleeting like some, but perpetual. I have never yet met anyone who was not charmed with the rich velvety flowers of Bardou Job or the glowing scarlet of Gloire des Rosomanes; and how beautiful they are when massed, especially if good bold groups are planted. Beds, some 20 feet across, filled with such Roses have a noble appearance, and they would be even more so if a few short standards of the same were planted in the centre to lift them up a little. I further strongly recommend the following as suitable for forming stately beds such as I have alluded to:—*Tea and Hybrid Teas*: Longworth Rambler, Mlle. Marie Lavalley, Mme. Wagram,

Belle Lyonnaise, Germaine Trochon, Billiard et Barré, and Cheshunt Hybrid. *Perpetual Scotch*: Stanwell Perpetual. *Rugosa*: Mrs. Anthony Waterer, Conrad Ferdinand Meyer, and Blanc double de Courbet. *Multiflora*: Leuchstern, Electra, and Crimson Rambler. P.

### SPRING PLANTING.

I IMAGINE many postponed the usual autumnal planting in the hope of a drier time prevailing later on, and, although this is not the case, doubtless there has been nothing lost by waiting, as the plants have fared much better heeled in than planted where so much water abounds in the soil and subsoil. Surely one may reasonably hope for better weather in March, and with a fine heap of prepared compost ready so that each plant may receive a shovelful at the time of planting, the plants will have a good start. I am presuming that the land was deeply dug or trenched some time ago. How necessary it is to look after the thorough drainage of the beds and borders, not nearly so much attention is given to this matter as its importance warrants. A water-logged soil is most inimical to the welfare of the Briar stock, although this stock revels in a somewhat stiff soil, as may be seen by the examples in the hedgerows. The seedling Briar, with its long tap roots, also thrives best where its roots can penetrate deeply without being injured by stagnant water.

I think condition of soil is more responsible for success and failures in Rose growing than stocks. Many say that they cannot grow certain kinds of Roses, and that the seedling Briar is a failure with them. Let such kinds be planted out under glass in borders as carefully prepared as the market grower prepares them and not one will fail. Now if the fault was in the stock such Roses would not grow under glass. I readily grant that some sorts possess a more delicate constitution than others, and this is responsible for some failures outdoors. But no rosarian would plant these very tender Roses out without giving them a good sunny situation, at the foot perhaps of a wall or fence. Where this is not practicable rather than lose them it would be better to dig them up in autumn and heel them in in a shrubbery or at the foot of a wall or fence, then replanting in March and April. This used to be the old style of treating the dwarf Tea Roses. They were lifted and potted up every autumn and placed in cold pits, and I am not sure this would not be a good plan to adopt now in districts peculiarly affected by spring frosts or where other conditions are unfavourable to the Tea Rose. When planting in spring always prune the growths beforehand, even down to three or four eyes on each shoot.

PHILOMEL.

### CARNATIONS IN THE TOWN GARDEN.

**D**URING recent years town gardening has come into greater prominence, and this is due in a large measure to the influx of people from the country to the towns and the consequent rise of suburban houses and gardens. It is due also, in perhaps as great a degree, to the increased interest in gardening that has lately been apparent. It is not too much to say that everyone is fond of the Carnation, and there can be no town gardener who would not willingly include it in his collection of plants if only he were able to grow it successfully. The Carnation has many good points as a town garden flower; the plants bloom freely and for a long time, the flowers are excellent for home decoration, as they last well when cut, some of the varieties are sweetly scented, and a charming variety of form and colouring is now to be found among them. Some writers of recent date have gone so far as to say that the Carnation is not generally a satisfactory plant for the town garden, but it may safely be said that they had not exhausted the methods of culture or they would never have reached so pessimistic a

conclusion. While it is true that many fail to grow Carnations successfully in a town garden, it is no less true that others grow them well under similar conditions, and find that few plants give more pleasure during the summer months. It has been truly said that the Carnation will thrive where the Rose will not grow, and no further recommendation of its virtues as a town garden flower could be wished, for we have seen Roses that carried away prizes at an important exhibition gathered from plants grown within six or seven miles of Charing Cross. Like every other plant, the Carnation loves pure fresh air, and it would be folly to say that it will grow as well in the impure, often fog-laden atmosphere of a large town as in a country garden. Some plants are more accommodating than others, however, and fortunately the Carnation is one of them. Give it reasonable care and intelligent cultivation and the results will not be disappointing. It should not be forgotten that the Carnation is hardy; many seem to have the idea that if allowed to remain out of doors all the year round it will be killed by frost. Nothing of the sort if the proper varieties are grown. The wild Carnation (*Dianthus caryophyllus*), from which the varieties of to-day are descended, is still found growing on some of the old castles in England.

### SOIL AND POSITION.

To grow any plant successfully it is necessary, or, at any rate, it is a very great help, to know something of its likes and dislikes. More particularly is this the case when the garden in which one has to work is at a disadvantage so far as soil and situation are concerned, then, more than ever, careful attention to detail makes all the difference as to the results. It is important, therefore, to know that the Carnation likes a warm and sunny position. One would naturally come to this conclusion after learning that the Carnation grows wild on castle walls. It is said never to have been found growing wild in hedges and fields, where, of course, it would have a certain amount of shelter and shade. It is not always advisable when cultivating a plant to give it exactly the same soil and position as it enjoys when growing wild, for the altered conditions of life, and probably of the plant itself, must be taken into consideration. Some general idea of the conditions most likely to suit it may, however, be obtained from knowledge of a plant's position and environment as growing wild. In the shade Carnations lose vigour, their soft stems and growth are likely to be adversely affected by wet, and the flowering season is shortened. Choose, then, a border that is well exposed to the sun, but which at the same time is not draughty, for cold winds play havoc with a bed of Carnations. In a town garden there is not much danger of harm resulting from cold winds, for it is usually well protected by neighbouring houses and walls. Still, the point is worth bearing in mind. The

### SOIL

is an item to be carefully considered, for upon its composition and preparation depends in a large measure the success of the plants. The Carnation does not grow well in poor soil. One of our best amateur gardeners says: "It is very difficult to grow Carnations in very poor soil; even when it is carefully prepared they still feel its starving and drying influence, and show their distaste by unusual shortness of life." My experience of the soil of an ordinary town garden is that it can, with a little cultivation and manuring, be made a fairly good medium. If it is sandy or gravelly to a large extent, of course it is a more difficult matter to improve it. But even then the continual addition of road scrapings, dead leaves, kitchen garden refuse, and a good dressing annually of farmyard manure will work wonders. Usually, however, the town garden soil is too heavy and wet, although at the same time it is poor, i.e., deficient in plant food. Artificial manures are of great benefit to such a soil as the latter, while they are almost useless to the former. They are best if applied as a top-dressing when the plants are growing, and preferably in showery weather, so that the manure may be at once washed down to the roots.

In sandy or gravelly soil all the properties of the manure would be washed away owing to the porous nature of the former. To improve poor, heavy soil it should be well dug in the autumn, and left unbroken during the winter. The action of the frost pulverises the large lumps, and renders the soil friable and more conducive to root growth. Some manure should at the same time be dug in and buried about 6 inches below the surface. Then in early spring the soil should be dug over again; this will thoroughly mix the partially-decayed manure with the soil, and will also break up the latter and render it more suitable as a planting medium.

Autumn is usually considered to be the best time for planting Carnations, and for gardens in the country, where pure air and suitable soil are enjoyed by the plants, it is undoubtedly preferable, for they become well established before the winter, and are able to make a good start in the spring. But for Carnations in the town garden I have no hesitation in recommending spring as the best time for planting. If the plants are put in the ground in early autumn it is true that they are well rooted before the cold weather; but how many of them are worth anything when the month of March arrives? It will probably be found—for such I have known to be the case many times—that most of them have lost their centres, or the leaves are in a sorry plight. Hundreds of Carnations in town gardens are lost during the winter months as the result of the centres of the plants decaying; the wet gets in the axils of the leaves and remains there for days, or perhaps weeks, for, owing to the absence of sun, there is no chance of its drying up. We have had exceptionally wet winters lately, and the loss among town garden Carnations has been great. It is not the frost that kills them, but the continual damp in and around them.

T. H. H.

(To be continued.)

## TREES AND SHRUBS.

### CLIFTONIA LIGUSTRINA.

**N**INETY years ago this shrub was in cultivation in this country, for in 1814 it was figured in the *Botanical Magazine*, t. 1625. Whether it is in cultivation now is, I think, doubtful. It is, at any rate, exceedingly uncommon, and I do not recall having met with it anywhere in English gardens. In recent years it has been offered by American dealers as a hardy shrub, but what has been supplied under the name to Kew has turned out to be a species of *Cyrilla*, a nearly allied genus, but quite distinct. The *Cliftonia*—there is but the one species—is a native of Carolina and Georgia, and ought to be hardy in the warmer parts of these islands. It was first discovered by the famous old American collector, John Fraser. It is an evergreen shrub with dark green leaves, and bears a terminal spike of white flowers in May. As stated above, it is closely related to the *Cyrillas*, of which at least one species—

*C. racemiflora*—is in cultivation; but besides other distinctive characters it is readily distinguished by the flower scapes being terminal. It would be interesting to know from readers of *THE GARDEN* in America if the true *Cliftonia* is obtainable there.

### CYRILLA RACEMIFLORA.

**T**HOUGH this shrub was first introduced to Britain in 1765, it is now, as it always has been, a very rare plant. It is a native of North Carolina, and is said to occur in Florida, where it assumes the dimensions of a tree, also in the West Indies and even Brazil. If this be so, the species no doubt is one that varies considerably, and it is only the most northern representatives of it that are likely to be hardy in this country. The specimens in cultivation, at any rate, are from Carolina and Georgia, and they are small shrubs as yet. In several works this *Cyrilla* is spoken of as a greenhouse plant; no doubt this is correct for many parts of the country, but at Kew it has grown out of doors for several years past without protection. Of course, our recent winters have furnished no real test, but it is certain that it would flourish in the gardens of our south-western counties. On the question of hardiness it may be mentioned that the American botanist Nuttall records that in 1840 he found in John Bartram's garden, near Philadelphia, a tree of this *Cyrilla* 20 feet high, with a trunk 26 inches in diameter. Not only is the species pretty and distinct, it is also one of more than usual interest. Messrs. Veitch exhibited it in flower at one of the Royal Horticultural Society's meetings in 1901, and it is also offered for sale in some of the American catalogues.

It has deciduous, somewhat Privet-like leaves, 2 inches to 3 inches long, about 1 inch wide, and of obovate outline. The flowers are very small and white, and are crowded on slender cylindrical racemes 3 inches to 6 inches long. These racemes are clustered in a horizontal whorl at the base of the current season's growth, and appear in July and August.

W. J. BEAN.

## AN ENGLISH INDUSTRY.

### BULB GROWING IN SOUTH LINCOLNSHIRE.

**D**OWN in South Lincolnshire, and more particularly in the county division known as "The Ports of Holland," the growing of all kinds of bulbs for the wholesale market has of late years become a highly important industry. Spalding—one of the oldest towns in England—together with an outlying hamlet called Little London, devote at least 150 acres to the cultivation of bulbs, and the growers are mostly men of substance.

Other nurseries are to be found in the parishes of Moulton, Whaplode, Long Sutton, Boston, and Wisbech. The last-named, however, is in Cambridgeshire, but being just over the border of the county of Lincoln the soil is of the same rich alluvial character as that of the neighbouring shire.

Messrs. J. T. White and Sons are the biggest growers in the Spalding district, and recently I made a special visit to this neighbourhood on behalf of *THE GARDEN*, and was conducted over the firm's extensive grounds by Mr. Alfred Willis White, who is one of the junior partners. At this time of the year the most important part of the work is the raising of forced blooms for the markets of the large cities, great quantities being despatched by rail twice a week to London, Birmingham, Manchester, and even to far-off Edinburgh. In order to bring this about, during September the bulbs, in lots of some 300, are planted in thousands of boxes filled with 3 inches to 4 inches of ordinary soil, and laid out in the open. About the first week in December the boxes are removed to one of the houses, where a temperature of some 60° is maintained, and with moderate watering the bloom is ready to pull in the middle of January.

Mr. White told me that this year they have had nine large houses filled with the double yellow *Daffodil*, *Narcissus poeticus ornatus*, *princeps Horsfieldi*, *Emperor*, and others. Those that I saw made a very brave show indeed, and of these forced blooms alone several million heads will be gathered before the open air stocks are touched. Year by year the demand becomes greater, not for blooms only, but for the bulbs themselves. And whereas years ago stocks were purchased from the Dutch growers, several tons of Lincolnshire bulbs were in January shipped to Holland, Messrs. White being the consignors. With regard to open air bloom it is almost certain to be late this season owing to the sodden and cold condition of the land. Mr. White's firm make a point of gathering the bloom in the half-opened stage so as to get it in as clean as possible. The bloom is then placed in a moderately heated house to finish development, and when fully open the flowers are hardened off for a few hours in a cool shed, being put in wooden gratings fitted over little zinc-lined tubs. After this the gratings or trays with their burden of flowers are taken to the bunching shed, where the bloom is tenderly tied by some twenty to thirty women and girls.

The bundles are then taken in hand by the packers, the method of packing being a particularly careful one. In the nursery that I am describing all the boxes used for this purpose are made on the premises, some 20,000 being kept in stock, and each box is capable of holding anything from 300 to 1,000 blooms. The packer lines the box with blue paper, on which she lays the flowers with their face upwards. When the first row is finished a stick of the width of the box is pressed down close under the chin of the flowers, and their wet stalks covered with paper so as to prevent any damage being done to the bloom of the next row.

Of the wholesale prices, I was requested by all growers with whom I came in touch not to mention the actual figures, although I was informed of them for my private guidance. Owing to the unfavourable weather, both last year and this, prices are and will rule fairly high. A small grower told me that from one week's cutting of his house of *Narcissus ornatus* he had made nearly £20. Most of the bloom is disposed of through commission agents, and

EARLY NARCISSI GROWN FOR MARKET IN LINCOLNSHIRE.

in fine hot weather the grower often loses heavily by reason of the market being overfed.

#### MR. ARTHUR STILES' GROUNDS.

Almost adjoining the grounds of Messrs. White is the bulb nursery of Dr. Arthur Stiles. Dr. Stiles took up the growing of bulbs as a hobby some twelve years back, being content at first with one little rood of land. About four years ago, however, he threw up a lucrative practice in order to give his whole time to bulb-growing as a trade; in his nursery he now cultivates, both under glass and in the open, some twenty varieties of Narcissus, and having always had his heart in the work Dr. Stiles knows perhaps as much of bulbs as does Dean Hole of Roses. While chatting with me about his work, Mr. Stiles—as he now prefers to be called—said that in the first week of February he had cut 75,000 Narcissus ornatus, all grown under glass, and that he and the other growers would continue to cut forced bloom until the Scilly flowers began to find their way to market in large quantities. The following are some of the chief varieties grown by Mr. Stiles out of doors, and flowering in the order given: Double Daffodils, coming early in March, followed by Golden Spur, princeps Sir Watkin, Horsfield, Empress, Emperor, Double Orange, Phoenix, Ornatus, Pheasant Eye, and double white Narcissus, which last is sometimes sold as a Gardenia. The season extends from the early part of January, when the forced double Daffodils are ready, to the middle of June, finishing with the double white Narcissus. Those bulbs which are forced generally take about four years to recover.

During Passion Week the station at Spalding is crowded with thousands of boxes of bloom bearing labels to all parts of the country, and special trains of eight to ten vans are run. Last season more than 500 tons of Narcissus bloom were sent away, and a special weighing apparatus was put down by the railway authorities so as to expedite the handling of the traffic as much as possible.

#### WOMEN WORKERS.

As in the Potato industry, which is now the most important in South Lincolnshire, women

workers are largely employed on the bulb farms. The women, however, are not so well paid as the "tater-pickers," as for gathering, tying, or packing the bloom they receive but from 1s. 6d. to 2s. a day. It must be remembered that the work is far lighter in every way, and that part of it is done under cover. A good woman worker will pick perhaps 10,000 flowers in a day, or if she is engaged in bunching will tie about the same quantity. To work the land

#### PIONEER OF SOUTH LINCOLNSHIRE BULB-GROWING.

was a Mr. Dickenson of Whaplode, who commenced operations some sixty years ago. The business is now carried on by his son, who is a very well-known grower and buyer too, and, like all prosperous men, he complained to me of the income-tax, but he did it with a sly twinkle in his eye. Of Aconites Mr. Dickenson says that they will not bear overmuch cultivation, and that therefore

he buys more than he grows; in fact, he has just given an order for 200,000. The Aconite really grows best in plantations and under trees generally. You will often find beautiful masses of it mixed with Snowdrops around old manor houses, and I know one lady, Mrs. Crawley of Whaplode Manor, Holbeach, who adds considerably to her "pin money" by disposing of the seeds and the tuberous roots. Strictly speaking the Aconite is not an Aconite at all, it being the botanical *Eranthis hyemalis*. The Aconite proper is, of course, the brilliant blue Monkshood (*Aconitum Napellus*), which is used by the doctors for heart trouble; and many a farm animal has been poisoned by eating the foliage. The Winter Aconite—to call it by its popular name—blooms as early as the middle of January, and lasts until the end of February to the beginning of March. The Buttercup-like flower is most happily set in a whorl of dark green leaves, flower and foliage being on the same sturdy stalk. The neatness of the growth makes it sit wonderfully well as a buttonhole. And it has often occurred to me that, were it put on the London streets, it would find a ready sale, for its general effect is quiet and gentlemanly. But the growers have been telling me that the flowers will not last. As to this I have worn the same flower for two days in succession, and have had a little vase

THE POET'S NARCISSUS IN THE ALPS.

(From a photograph by Major McKenzie, and kindly sent by M. Correvon, Floraire, Geneva.)

with the spade is, of course, impossible when so many acres are under cultivation, the plough being used as for ordinary field work. The effect of the industry upon Little London has been to raise it from a poverty-stricken village to a comparatively flourishing hamlet, as most of the inhabitants, men, women, and children, are employed in the nurseries in one capacity or another. The

of Aconites on my study table for a week, and as I write I notice that they are but now beginning to fade. Will my friends the enterprising growers please note?

The Winter Aconite is one of the most charming of early flowers, and is very pretty at the foot of trees or in a bed filled with Scarlet Dogwood (*Cornus sibirica*).

TOYE VISE.

## THE LAWN.

**A**MONG the many features of British gardens it is not too much to say that the lawn occupies a foremost place. The English garden-loving public have possessed lawns of surpassing beauty and extent for so long a time that in a measure their value as aids to the furnishing and beautifying of our private and public gardens is looked upon as a matter of course, and discounted by this familiarity; yet if the charm and interest of the lawns were withdrawn our pleasure grounds and gardens would be left poor indeed.

For many features of our gardens we are indebted to the wealthy and generous patrons of horticulture in this country, but for the lawns we are not so much indebted to these agencies as we are to the free gift by Nature of a climate and soil so eminently suited to the growth of lawn grasses. In the past I have often had the privilege of coming into contact with eminent horticulturists from many parts of the world visiting England for the first time, and it is not too much to say that what they all with one accord admire most in English gardens are our lawns. It is altogether a new revelation to them, and in their estimation is one of those beautiful aspects of gardening which no other country in the world possesses in the same degree. So much do owners of gardens abroad wish to have such lawns as we enjoy that no labour or expense is spared. This is only possible by cultivating and sowing the land with new seed every year, the same as we do in this country for the purpose of growing corn, the land being broken up every autumn and resown with new seed at great cost, and watered and cultivated during summer with as much diligence and care as we bestow on our most cherished crops.

### FORMATION OF A LAWN.

If the land to be formed into a lawn is part of a field of good turf, and the natural contour of the land is pleasant to look upon and devoid of angular and ugly formations, the expense

and labour in this instance will not be great, and will consist chiefly in levelling any small irregularities there may be, and in giving a good dressing of rich soil to fill the many small depressions or holes, and to nourish the grass, causing it to assume that deep green shade of colour we all so much admire. The surface of the land should be rough harrowed in spring, and a good dressing of soil (with  $\frac{1}{2}$  cwt. of bone-dust to the cart-load added) applied, and well rolled in with a heavy roller after showers of rain. March is a good time to carry out this work. When mowing time comes round the first crop must be cut off with the scythe. The lawn mower may be used afterwards, as the surface soil will then have disappeared among the roots of the grass, and the mower, if used every ten days (or oftener if the weather is damp) during summer, will in a short time transform an ordinary field into a beautiful lawn. In the case of extensive lawns such as we have been considering owners of gardens engage experienced men to carry out the work; but there are many others having smaller gardens and more limited means who would be delighted to superintend and direct such work with the assistance of less skilled workmen. To such a few suggestions as to how to proceed to lay down a new lawn may be acceptable.

It is useless to hope to secure a beautiful turf of the best grasses without the land in the first place is efficiently drained, either naturally or artificially. If the soil is shallow, and resting on gravel or chalk, no artificial drainage is necessary, but if on deep soil of a marly or clayey nature then the land must be

### WELL DRAINED.

In land of this description the pipes must not be laid too deeply; in stiff clay 18 inches will be deep enough; and in soil not so retentive 2 feet will be better. The drains must have a moderate fall (towards an outlet) of at least 1 foot in 100 yards; more would be better. The distance between the 3-inch drains in heavy clay should not be more than 15 feet, and in soil not so heavy 20 feet would be a suitable

distance. Supposing the land about to be converted into a lawn to be already under good sound turf, the first question to consider is whether the surface is of an uniform level or possessing pleasing undulations. Should this be so, then the instructions already given for bringing the turf into proper condition would apply. On the other hand, if consisting of angular and objectionable elevations and depressions, the turf must be taken off and put on one side ready for relaying, the land ploughed or dug deeply, the objectionable irregularities reduced by the harrow fork and rake, and the turf relaid. If the grass is rough and coarse then it will be better to dig it deeply under and sow the land with the best mixture of lawn grass seed suitable to the nature of the soil, and which may be obtained from any of our seed merchants.

### CUTTING AND RELAYING THE TURF.

This work may be carried out any time between October and the end of April (and, indeed, by the experienced man during any month of the year in case of necessity). The tools it is necessary to possess to carry out this work are an edging knife, turf knife (or plough, as it is sometimes called), and a garden-line. The turves should be cut into sizes 2 feet long by 1 foot wide and 3 inches deep. They should be rolled up and put by in convenient heaps ready for relaying. When they are cut into this uniform size relaying is greatly facilitated and the work carried out much more satisfactorily than if the turves are cut in a haphazard way. Dry days in winter and showery days in spring should be selected to carry out the work. Before the turf is laid the surface of the soil should be made smooth and even with the rake, and the turves well pressed down with the feet as soon as laid. Towards the end of April it will be found that the sun has somewhat contracted and warped the turves, thus leaving spaces between them. A dressing of soil should then be given in order to fill up these openings, and the dressing should be extended to the whole of the turf, and a thin sowing of lawn seeds made, at the same time raking it well in and rolling several times over. This light dressing of soil will prevent the turves drying so quickly, and help them also to re-establish their growth much quicker than would be the case without it. As soon as the growth of the grass is active the soil dressing will disappear.

### MAKING A LAWN FROM SEED.

There are advantages and disadvantages associated with each system. Laying it down with turf enables the lawn to be used either for playing or walking upon much sooner than when seed is sown. On the other hand, it seldom happens that the old turf is composed of such suitable varieties of grasses as the lawn laid down with seeds would be, as these are selected with great care, in that proportions of sorts and colours which long experience has taught to be the best. The preparation of the ground will be the same in the case of seeds as that recommended for laying down the turves, excepting that if the land is at all poor a dressing of at least

DWARF LAVENDER AT FOOT OF DRY WALL.

15 tons of good farmyard manure to the acre should be applied. The best time to sow seed in the South of England is from the middle of March to the end of April. In the North and Northern Midlands three weeks or a month later would be better. Seeds may also be sown in the autumn from the middle of August to the middle of September. The only disadvantage of sowing in autumn is the danger of injury to the young grass by severe frost during winter.

OWEN THOMAS.

(To be continued.)

## WALL GARDENING.

### SOME SUGGESTIONS.

**W**E feel no excuse is necessary for giving prominence to the subject of wall gardening. During recent years outdoor gardening has undergone a vast and delightful change.

We see positions for creating pictures of rare charm and beauty hitherto unheeded, and our eyes are opened to ways of adding enjoyment to country life pursuits by simple forms of English gardening. Wall gardening is one of these, and we draw attention to it now, as spring is one of the best times to sow seeds, to bring some of the charms of many an old castle keep to the walls of the homestead. Ways of gardening scarcely thought of a few years ago are now being taken up with great eagerness, and the good gardener seeks to make gardens of living beauty of the water surface and the wall. As a well-known writer upon wall gardening recently said: "The better knowledge of many of the beautiful flowers of the Alps has shown that, though some are plants for our garden borders, and a still greater number will suit our rock gardens, there are many, and among them some of the most beautiful, that are plants whose right home in England is an actual wall."

We have not, except in a few favoured gardens, such natural walls as many alpinists have the benefit of at home, but most gardens have some kind of walls, while many have retaining walls of unmortared stone—what are known as dry walls. Now we have come to see how valuable these places are, for there are a good number of the mountain plants that can only be grown successfully in an actual wall, where their roots ramble back into the cool stony depths, and the heads are in full sunlight. In many gardens, too, there are steep turfy slopes, which can be made into rough walls in which numbers of beautiful mountain flowers will spread freely and flower abundantly in their appointed seasons.

Wall gardening is a fascinating study, full of possibilities, and as yet little understood. But the mossy flower-stained walls of many an ancient keep, or some low cottage wall, should surely teach us that this form of gardening might enable one to grow many a rock flower that now languishes for want of just those conditions that the wall affords. Those who have thick mossy old walls possess a paradise for many a rock flower, and it is only necessary to go over the walls, pick out the weeds and rubbish, and retain as much of the moss as possible to provide the right conditions for the plants. Never try and make a rock garden of this wall surface, but wisely choose first those things that we know will do well, and then as knowledge increases add others, until an extensive collection has been got together. Masses of Wallflower, Arabis, purple Aubrietia, Valerian, the noble leaved Mulleins, Sedums,

Saxifrages, and Ivy-leaved Toadflax are the plants to begin with, and so sow the seed or put in the little seedlings that a rich splash of colour is the result, not a dotting of a hundred things for the sake of a mere collection.

It is a wonder that this beautiful way of growing many an alpine flower has not long ago gained the affections of the earnest gardener. There are object-lessons in the wild wall growths, the thick clustering of Ferns, and the colonies of Snapdragon and Foxglove. These and many other flowers as beautiful grow contentedly with no other support than decaying mortar, and surely make a glorious return for their small wants. As the writer referred to points out: "A wall of living beauty is possible before the mixed border has become established, or in gardens where no rock garden is possible, many beautiful alpinists that love to send their roots into the crevices are quite as happy here—even more so—than elsewhere."

Sometimes there are in the garden rough stone steps leading perhaps to an outhouse or loft. In the crevices of the stones it is possible to establish many a flower, and we well remember in a Surrey garden seeing the crevices of steps of this kind full of *Erinus alpinus*. A few seeds of this pretty flower were scattered in the joints, and mossy tufts grew and thrived, taking to the somewhat unpromising place with a cheerful vigour that was more than the expected reward of what was only ventured upon as a piece of experimental planting. So that one may confidently advise anyone who has a bit of moss-grown wall or steep stony bank to sow *Erinus alpinus*, and leave the accommodating little alpine to do the rest.

A host of plants may be raised from seed and the seedlings pricked into the wall, or the seed can be sown in the chinks, but when sowing such things as Wallflowers and Snapdragons be careful that the seed is derived from a good source. We made a liberal sowing of Snapdragons in an old wall, but the results were not gratifying, the flower colouring being poor and the growth stiff and dwarf. None of the squat and pigmy forms of naturally beautiful flowers should find a place in the wall, or, indeed, in any part of the garden. Many plants not considered wall plants are happy in chinks into which they can thrust their roots.

Situation has much to do with the success of wall gardening. Shade-loving flowers are unhappy in full sun, and the wall gardener must be ever mindful of the intense heat plants

CERASTIUM IN A DRY WALL.

are exposed to on a surface of brick or stone. We once noticed in a garden *Arenaria balearica* drying up on a wall in full sun, but spreading freely in a moist, half-shady spot. It is by studying the nature of the plants that success is attained, and only in this way does gardening become a pleasurable and instructive pastime. The glory of many an English village and homestead is in the thick moss-stained walls where a hundred lovely flowers have sent their roots into the chinks and painted them with tender colouring, drifts of yellow from Toadflax, and many other wildings flinging their stems from their rocky hold.

## THE FLOWER GARDEN.

### THE IMPORTANCE OF THINNING ANNUALS.

**I**T is an excellent practice to sow many of the hardy annuals, *e.g.*, Shirley and other Poppies, Cornflowers, the various Californian species, &c., as well as biennials, in the early autumn. Those who have not tried the plan can scarcely realise the gain, in normal seasons, to the flower garden in spring. This last season, however, all our best-laid calculations have "gone a-gley," for in most parts of the country seedlings have been either washed bodily away or have damped off the surface of the sodden earth. If any of them should have been strong enough to outlive such drastic treatment—and they have in some favoured gardens—

they may still be transplanted from the seed-bed to their flowering quarters, where, if allowed plenty of room to develop, they will attain noble proportions and go on blooming for a long time. But whether or no this be the case, there is always spring sowing to be done as well, and the time for it is at hand.

Annuals are amongst the most important additions to our summer and autumn flowers, not only on account of their intrinsic beauty, but on the score of their usefulness in filling up, at short notice, the gaps which will occur even in the best

regulated gardens. In working up a good stock of them, however, whether hardy or half-hardy, everything depends upon the treatment they receive, for even the finest strains of seed may easily be ruined by want of judgment or neglect. To begin with, it is worse than waste, for it is disastrous as well, to sow at the rate of a hundred seeds for every twenty-five seedlings required. Good seed may be reckoned upon to germinate freely, and those that come over and above the number wanted will choke the life out of the remainder, and we may be left in the long run

without a single seedling worth the saving. To take a familiar example, a single well-grown plant of *Nemophila* set by itself will carpet 2 feet square or so of bare earth, and is a beautiful sight, as it seems to reflect the blue of the April sky. But sow the seeds in thick-set patches in the open and leave them without thinning in the usual way, or allow the seedlings to spindle up in pots to be transferred just as they are later on to the border, and *Nemophila* presents a miserable spectacle, not to be recognised as the same plant. Sweet Peas, the most popular, perhaps, of all annuals, are more

sinned against in the matter of too liberal sowing, and that out of sheer admiration, than almost any other class; but the same remark applies to almost every kind of annual plant, whether useful or ornamental. Experienced men know this well and act upon it, thinning out their lines of vegetable crops, no less than with their seedling flowers, to an extent which makes the tyro predict but a scanty harvest. All the same, they know perfectly well what they are about, and the result proves it. All gardeners, however, and especially amateurs, are not as yet experienced, and for such this fact cannot be too strongly insisted upon, that success or failure with annuals, and, indeed, with seedlings of all kinds, depends mainly on sowing as thinly as possible and taking care to prick out the young plants in good soil before any overcrowding can take place.

Sowing in the open ground in spring is rather hazardous work in the case of choice annuals, and should never be attempted with valuable seed. It is better, generally, to sow in pots or pans, pricking out the seedlings into boxes as soon as they are large enough to handle. For many of the larger-growing annuals, like the fine *Arctotis grandis*—and even for the yellow Sultan and its new white counterpart, which are somewhat difficult—it is best to put each seedling separately into a 2½-inch pot, giving another shift or two as required before planting out. This may seem to entail a good deal of extra trouble, but it will be amply repaid at flowering time. The nurserymen who sell penny packets of counted seeds have taught one very useful lesson to their patrons, that the growing of strong, healthy plants does not depend upon the quantity of seed that is sown. And a most important lesson it is, to fix in the mind once for all, hence this timely reminder now when seed sowing is the order of the day.

K. L. D.

## GARDEN VASES AT INWOOD.

**I**NWOOD HOUSE, Somerset, the seat of Mr. Merthyr Guest, is one of the most interesting in England. It has been the delight of Mr. Guest to adorn his pleasure grounds with fine leaden and stone figures—the works of old masters in that neglected art. We have many a time spoken of the extreme beauty of the colour of old lead, and its great suitability for garden work. Far better is its hue than the garish blaze of marble, or even than the fine character of bronze. In old English gardens leaden figures were not uncommon, and in many of them, as at Melbourne in Derbyshire, they still remain. Mr. Guest has exercised eclectic taste, and has brought to his Somersetshire home examples of

THE FRUIT URN AT INWOOD.

English skill both in lead and iron, and also of the work of French and Italian hands. The result is admirable, and in few places can there be so good a collection. The many ancient leaden figures, vases, water-tanks, and cisterns are well placed for effect, sometimes standing apart, and in other cases framed, as it were, in niches in the hedges of Hornbeam or Yew. These charming examples of garden sculpture thus give the air of an old-world pleasaunce to this garden, though, in fact, it is comparatively modern, nearly the whole having been laid out within the last twenty years.

Among the many sculptured adornments of the place is a fine bronze reproduction of the famous Laocoon, attributed to Agesander, Polydorus, and Athenodorus, the Rhodians. The unhappy son of Priam and Hecuba, gripped in the horrid coils of the vengeful serpents, as, with his two boys, he offered sacrifice to Poseidon on behalf of the Trojans, does sometimes appear in gardens, without, however, lending the charm of repose that we love in our pleasaunces. Evelyn found a Laocoon at St. Cloud, amid the multitude of statues there, and describes in glowing terms the Laocoon fountain, which threw the water nearly 40 feet high, and was a "surprising object." The statuary group in question marks the strong recoil from the effeminate style of the Praxitelean School, and possesses anatomic exaggeration and unsculpturesque energy of action that caused Ruskin to say no group had ever exercised so pernicious an influence on art. There is a lesson here. Let us admire the Laocoon at Inwood House, which, indeed, is not used there as a garden feature, but let us recognise that a figure in repose is more suitable for our garden adornment—a gladiator resting after his toil or a Narcissus pensive by his pool. We reproduce the beautiful flower and fruit vases at Inwood, and also one made by Mr. Pulham of Broxbourne.

### RECENT PLANT PORTRAITS.

THE March number of the *Botanical Magazine* contains portraits of

*Oldenburghia Arbuscula*.—Native of South Africa, also known under the synonym of *O. grandis*. This is one of three known species of the genus, and is more of a botanical curiosity than anything else, its flowers closely resembling those of the common Artichoke, though of less actual beauty of colouring. They are borne on the top of a low-growing shrub, with thick, deeply ribbed foliage. This plant was raised from seed brought from the Cape in 1887, and has taken sixteen years to reach a height of about 3 feet.

*Tanakaia radicans*.—Native of Japan. This plant is merely a botanical curiosity, and of no beauty whatever.

*Kirengeshoma palmata*.—Native of Japan. This is a handsome, profuse blooming, and most interesting plant, with good-sized, light yellow flowers. This plant was described and figured in THE GARDEN for October 10 of last year (pages 245-6).

*Solanum glaucophyllum*.—Native of Brazil and Uruguay. This is by no means a new plant,

having been cultivated in Paris three-quarters of a century ago. It is, however, a plant of considerable interest and beauty, producing large bunches of handsome cup-shaped rosy purple flowers, followed by purple egg-shaped fruit. It has been in cultivation at Kew many years, and flowers and fruits annually in the Temperate house.

*Meglaclinium platyrrachis*.—Native of British Central Africa. This is an Orchid of considerable botanic curiosity, but no beauty.

The second number of the *Revue Horticole* for February contains an excellent portrait of the

beautiful and well-known *Tropaeolum speciosum*, showing both the brilliant scarlet flowers and the flowing triplets of deep blue fruit. The first number of the same periodical for March figures the now well-known and brilliant *Crassulad* (*Kalanchoe Kirkii*), but hardly does this fine plant justice either in size of flower or brightness of colouring. It first bloomed in the Royal Gardens, Kew.

The *Revue de l'Horticulture Belge* contains a portrait of a very pretty terrestrial Orchid bearing the very long name of *Anæctochilus thomsonianus* var. *Gentilii*. W. E. GUMBLETON.

A FLOWER VASE AT INWOOD.

## BALCONY GARDENING FOR THE LONDONER.

"Visions of blue Violet plots,  
White Daisies and Forget-me-nots."

SOME of us have a balcony as well as a window-box. Here is a field indeed; we have more space, more opportunity for display. Rescued from the hands of the florist, balcony gardening becomes one of the most interesting of occupations. Here we may aspire to creepers and climbers, in addition to shrubs and flowers; in a good aspect (if we look after them ourselves) even to Roses. Imagine it in London!

"Rose trees either side the doorway,  
Growing lithe and growing tall,  
Each one set, a summer warder  
For the keeping of the hall."

Climbers in pots that make quick summer growth are easiest to manage. These we can get fresh every season, and they greatly brighten up the old friends that have lived with us from year to year through the adversities of frost and fog. Major *Convolvulus* and the perennial *Morning Glories* do well; also *Canariensis*, but all these must have sun.

For a town wall plant nothing can surpass the winter *Jasmine*, whose yellow blossoms cheer the dulllest months, and in summer we welcome its long, green trails, which we must not forget to cut back every autumn, or it will get too straggly. It is always the year's young shoots that are wanted for beauty. *Forsythia*, with its golden flowers of February and March, delights us sometimes on the fronts of London houses in very early spring, but the foliage is not so decorative afterwards, and for the balcony we must have summer beauty. The *Virginia Creeper* that we have brought from the generous West (along with other pretty things) is now so familiar that we forget it is really a newcomer. It was in 1841, at the back of a house at Rutland Gate, that the *Virginia Creeper* made its first appearance in London. Since then how much it has done to beautify our towns, both the common kind and the small-leaved *Ampelopsis Veitchii*, whose habit of self-clinging renders it so invaluable! Some critics think we use this creeper too freely, but I do not agree with them. Either on grey stone or brick or trellis-work or rails its graceful festoons of green or red or crimson—as the sun has dyed them—give summer brightness, and are a never-failing autumn joy. The *Grape Vine* and *Fig tree* both do well in London, also the deciduous *Magnolia*. Of the *Ivy* there is no occasion to speak, except to remind that there are more kinds than one. Good balcony shrubs for backgrounds are also easily found, and in many contrasting tints of green and gold. With respect to pot plants, Mrs. Earle gives a suggestion that is worth following up:—"One day outside a dining-room window of a London house I noticed some large, heavy, oblong Japanese flower-pots planted with single plants. They looked very well, as one was able to see the growth of the plants. The pots were glazed and much thicker than the ordinary flower-pot. This lessens evaporation, and their weight prevents them from being blown over." Ordinary flower-pots are not suitable in our climate for outer windows and balconies.

I am convinced that for furnishing the balcony there is a great future for strong, well-made, handsome pots. It is wonderful what can be grown in them. No one understands this better than the flower-lover who has ever lived in any of the West Indian

Islands, where there is no soil, and everything has to be grown in pots and tubs. Tubs are charming—so cheap, so easy to manage, and so decorative when tastefully painted. Plants always take kindly to tubs, and both tubs and pots can be arranged or moved about with ease, a great convenience when ladies undertake the work.

But tubs and pots are not the only receptacles that are useful for balconies, verandahs, leads, and windows or doorways. Italian oil jars answer very well, either whole or sawn in half to make two. Seakale pots serve the same purpose. For painting them in colour

THE "PARIS" VASE.

(Designed by Messrs. Pulham and Son.)

nothing is better than a low-toned green, which harmonises with all else. There is a certain dull red that pleases some tastes, but red is a colour that ties.

The quality of the material of the receptacles must be considered carefully, as it has a great deal to do with the amount of water the plants will require. Ordinary flower-pot ware is very porous, and plants grown in large flower-pots require more frequent watering than when grown in anything else. The evaporation through plain wood is not nearly so great as through unglazed earthenware, and when the wood is painted it is still less.

Glazing an ordinary flower-pot makes it more protective. Old petroleum barrels (when the oil has been turned out) and butter-tubs are excellent plant-holders, but of course must have ample provision made for drainage and several good-sized holes must be pierced at the bottom.

If the tub or pot has not much depth of room underneath it should be set on bricks or raised in some other way. This assists drainage and keeps the holes from being blocked by worms or otherwise. Repotting is very seldom required if in the first instance good compost is given. The best way of feeding our tub plants and shrubs is very well explained in a paper on "Tub Gardening," by Mr. Alger Petts, in *THE GARDEN* of September 21, 1891. It is well worth study by those who mean to take seriously to tub gardening, but most likely the tub gardeners of the London balcony do not expect their plants to live long. They would do so, however, if properly looked after and given a fair chance. One great advantage about flowering pot and tub plants is that they bear more blossoms grown in this way than if they were in the open border; the strength of them goes to blossom instead of root, as everybody knows.

London in June! how beautiful it is, especially at the West End, the best End, and who can doubt it owes much of its beauty to plants and flowers? There they are, in shops and dairies, even among the delicate confections of the modiste, pots of green Ferns, even fragrant blossoms. On a summer's day in Bond Street I have sometimes stopped involuntarily to feast my eyes on the artistic arrangement of a shop front, where blocks of ice and silvery white bait, the scarlet lobster and the subtle pinks of salmon mingle with trails of Grass and sea-weedy green. This is refreshing, but we should like more of it. Why should not our streets be even gayer than they are now and sweeter? Over the shop fronts and on leads, as well as in the window-box or in the balcony, we would see something fresh and growing.

Cut flowers are all very well, but they make only for beauty. The growing plant is a health-helper as well as a joy to the eye, for the carbonic fumes that kill us are positively good for plants; they live on and enjoy them. Trees and all green things are good, but trees, unless a street is very wide indeed, take up too much room, robbing us of light and preventing the air from circulating. Balcony gardening need never do this, we can keep to low-growing things and creepers. Many a town house has balconies large enough to lounge in. On a July evening, under the delicate thin curve of a new moon or in starlight, how sweet the summer dusk, even in London! There are fewer fires now and less smoke, and flowers are just as fragrant here as in the country. Where so welcome as in cities are "pointed blossoms rising delicate with the perfume strong we love." I was once a frequent visitor at a London house which was always kept full of growing plants, and could never enjoy one of them. Why? Because I knew each one was dying every moment. They were treated exactly like furniture. A dark corner would be "lighted up" by the splendour of a scarlet *Geranium* in full bloom (it did not remain scarlet long), a *Daphne* showed its pink stars on a davenport close to the fireplace, and a long way off the window. No one ever picked off a dead leaf or gave the plants so much as a cupful of cold water. Every few days the florist's man came round, took away the invalids (for such they had become), and arranged a fresh lot. Poor

plants! they had my sympathy. I do not think this treatment of flowers shows the least real love for them. Better were it to grow the humblest blooms out in the air upon the open ba cony.

F. A. B.

## THE FRUIT GARDEN.

### PEAR BEURRE RANCE.

**B**EURRE RANCE is one of the oldest, best-known, and largest of winter Pears. I have had fruits weighing nearly 1lb. each. It requires a south or south-west wall to bring it to perfection, and is in season from February to the middle of April. When well grown and fully ripe it is one of the most luscious and refreshing Pears I know, having a flavour of its own, quite unlike any other; the only fault that can be found with it is that the flesh is of a rather rough texture, and that its fruit occasionally cracks, but this only occurs on half-starved and badly-cultivated trees. In ordering trees from a nursery, double grafted ones should be asked for.

OWEN THOMAS.

### SOME TROPICAL FRUITS.

AMONG tropical fruits that are grown in hothouses in this country the Guava is perhaps the least commonly met with. I have never seen it thriving better than in the gardens at Harewood Hall, Yorkshire, where Mr. Jenkins grows it trained upon a roof trellis in a warm house. If I remember rightly, two plants are planted out in a narrow border, and from them a great many fruits are gathered. I am sure it would interest readers of THE GARDEN if Mr. Jenkins could be prevailed upon to recount his experiences of Guava culture in your columns. The two species best worth culture under glass in this country are *Psidium Guava*, from the West Indies, and *P. cattleianum*, native of Brazil. There are two varieties of *P. Guava*, says Mr. Watson, writing in THE GARDEN some time ago—*pomiferum* and *pyriferum*. "The fruits are green, not unlike a little Apple, with an agreeable, somewhat acid flavour. The Guava is largely grown in tropical countries for its fruits, which are eaten raw or form the well-known Guava jelly." The fruits of *P. cattleianum* are of a claret colour.

Guava fruits are said to be greatly liked by the few who know of and eat them, and it seems a pity that more gardeners do not undertake their culture, and thus add welcome variety to the list of dessert fruits grown under glass, which at times is found to be rather limited. The *American Fruit Culturist* gives some interesting particulars about the Guava. From it we learn that it may be called the Apple of the tropics. From its original home in tropical America it has become dispersed over all equatorial regions. As the tops, which succumb to several degrees of frost, are promptly renewed from the roots and bear in a few months, it is often grown in a small way in sub-tropical climates. As soon as the repugnance to its penetrating and rather unpleasant odour has been overcome, it is accounted one of the most fascinating of fruits, either fresh or made into jelly, marmalade, puddings, or pies. In productiveness it exceeds almost any known fruit tree. In sub-tropical regions the regular crop ripens gradually from August to October, but there are a few scattered specimens to be found maturing at all seasons. If the whole ripened at once the branches would bend to the ground with their load, of which there is a perennial renewal and no barren

years. In the tropics it is often a pest, springing up everywhere from seeds dropped by birds, and over-running abandoned plantations till they become transformed into impenetrable jungles. In Southern Florida it is an inmate of every garden, and some of the large, white-fleshed kinds brought from the East Indies are among the most delicious and fascinating fruits in cultivation. The author mentions *Psidium lucidum*, which bears fruits of a lemon or cream colour.

Another tropical fruit now much better known in this country than it used to be, but still not generally grown, is the Japanese Date Plum (*Diospyros Kaki*). I have grown them as bush trees in pots, and have fruited them fairly well. The large orange-scarlet fruits are very handsome. The plants were placed out of doors during the summer months and in winter were kept in a house where the temperature was 55°. This fruit is grown at Kew, but there the plants are planted out in a border. Mr. Watson wrote in THE GARDEN that "it is planted out in a border of loamy soil in a position where it gets plenty of summer sunshine and air, while in winter the atmosphere is dry and the temperature never below 50°. The pruning of this plant is identical with that recommended for Peaches. In Japan the trees are never pruned with a knife, the belief being that iron causes injury to the branches. They are therefore thinned by breaking with the hand. The soil most suitable for the Persimmon is loam, and a top-dressing of manure should be given annually, say in March."

The Japanese have worked hard upon their own native *Diospyros* until it has become the most highly esteemed of all their fruits, and the original little berries have not only improved in flavour but increased in size, till some exceed 1lb. in weight. Planted everywhere, it is now a conspicuous feature of the Japanese landscape, and, apart from its value as food, travellers unanimously agree in extolling the beauty of the broad glossy leaves and the brilliant crimson and golden tints of the fruit which clings to the branches after the fruit has fallen.

Other fruits that I might mention as being well worthy of inclusion in gardens where variety of dessert is appreciated are the Loquat and Passion

Flower fruit, to say nothing of the Mango, Custard Apple, and Tree Tomato, while the Banana, of course, is now fairly widely grown. A. P. H.

## CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

### PHORMIUM TENAX.

[TO THE EDITOR OF "THE GARDEN."]

**S**IR,—I am sending leaves of the New Zealand Flax taken from a plant growing in a north house among Ferns with but little soil to support it, and where the thermometer often registers 6° or 8° of frost. This plant is tolerably well known as a greenhouse and conservatory subject, but is not nearly so much grown as it ought to be. When grown to a medium size its leaves begin to arch over, and when in that condition nothing makes a more graceful and distinct plant for room or hall. It may be grown well in an 8-inch pot, or to a great mass of bold long leaves in a tub 3 feet in diameter. This plant will generally be found to enjoy a greenhouse temperature, though in genial places in the South and West of England it does very well in the open air. Its best use is for the decoration of the garden in summer, a few specimens well grown and plunged in the grass or the centre of a bed give a most distinct aspect to the scene. The larger such plants are the better the effect. Smaller plants will prove equally useful and effective in vases, to which they will add a grace that vases rarely now possess. It is useful for house, conservatory, and even living rooms in winter. Wherever indoor decoration on a large scale is practised it is indispensable. Unless for vase decoration it requires to be grown into good specimens before affording much effect out of doors, but when in large tubs it is equally grand for the large conservatory and for important positions in the flower garden. The variegated form lends itself equally well to the same treatment. Its leaves are striped with rich yellow and white.

PEAR BEURRE RANCE. (Slightly reduced.)

This colouring makes it a most desirable plant either for the conservatory or the flower garden.

T. B. FIELD.

*Ashwellthorpe Hall Gardens, Norwich.*

[We are glad to be reminded by several unusually fine leaves of the usefulness of the plant for a position such as is described by Mr. Field.—ED.]

### ERICA WILMOREANA.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—It is somewhat singular that the early history of this Heath, alluded to lately in the notes from Covent Garden, should, in common with the even more popular *Erica hyemalis*, be quite unknown. This last-named is the first to open, and is brought into Covent Garden Market some time before Christmas, but towards the end of February it is to a great extent superseded by *E. wilmoreana*, which, apart from its season of blooming, differs from the other in its more robust and spreading habit of growth, as well as in the flowers themselves. In the "Kew Hand List" both the above Heaths are referred to as of garden origin. They belong to that section known as soft-wooded Heaths, which term includes those that can be propagated by means of soft growing shoots, and which may as a rule be cut back without injury after flowering. This section embraces nearly all those which are popular with the market grower, the main reason being that saleable plants can be obtained in much less time than in the case of the hard-wooded Heaths, added to which most of the latter bloom in the summer when flowers are plentiful, whereas many of the market sorts, such as *E. gracilis*, *cafra*, *hyemalis*, *wilmoreana*, *persoluta*, &c., flower during the autumn, winter, and early spring months. T.

### A WINTER-BLOOMING VIOLA.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—The winter-blooming variety alluded to recently by Mr. R. Dean is one evidently much grown about Feltham. Two winters ago I noticed a big breadth of several hundreds of plants in a small hardy plant nursery close to the road. The variety was named Sulphur Queen, Lemon Queen, and something else. There can be no doubt that it is the most remarkable winter-blooming *Viola* in commerce. This sulphur *Viola* is well worth taking in hand as a seed parent, with the hope of breeding from it a special race of winter-flowering varieties. When I saw the variety I was informed that it is quite constant as a winter-bloomer. K.

## GARDENING OF THE WEEK.

### FLOWER GARDEN.

#### SEED SOWING.

AS soon as the soil can be got into workable condition the seeds of some of the hardier annuals should be sown outside. These are very effective if sown in patches in the spaces between the regular occupants of the herbaceous borders. When possible it is a good plan to prepare the soil, sow the seeds, and cover with finely sifted soil from the potting shed. The depth of covering will depend on the size of the seed, which should be covered rather more than when the sowing is done under glass. Periodical sowings should be made of Shirley Poppies and Mignonette to produce successional supplies for border display and cut flowers. The seeds should be sown thinly, and later on thinning must be rigorously practised. Annuals are apt to become overcrowded, with poor results. It will now be necessary to sow in heat such as Asters, Stocks, *Salpiglossis*, *Phlox Drummondii*, *Salvias*, *Helichrysum*, &c. Different methods are adopted, according to the various conveniences and requirements. It is essential to provide thorough drainage, so that the soil shall not at any time become stagnant. The seed pan, pot, or box should be covered with a piece of glass, slate, or tile to

prevent excessive evaporation. As soon as the seedlings are up air should be gradually afforded to prevent damping, and after the seedlings have recovered from the check of pricking out the sturdier they are grown the better.

#### BAMBOOS.

During the early spring rats are frequently troublesome, especially so if the Bamboos are growing near a lake or stream. At this time of the year the teeth of these rodents require a deal of grinding back, and as the stems of Bamboos are very hard and of a convenient size they utilise them for this purpose. In no other way can I account for the sometimes almost wholesale destruction of Bamboo culms by rats. At a height of about 3 feet they will partially gnaw through stem after stem. In these cases, as trapping is almost impossible and poisoning is out of the question, I have found a little patience and a gun to be the surest remedy. Unless a good look out is kept these detestable creatures strip off many of the leaves to line their nests, and when growth commences will eat the tender shoots.

#### YUCCAS.

In many places more use might well be made of these noble plants. When once planted, whether as single specimens or clumps in the grass or as a bed, they are but little trouble, and besides being evergreen a group or bed with a fair number in flower forms a most interesting feature in the garden. *Yuccas* thrive in a light, fairly rich soil. A good-sized bed may be made very effective by planting *Y. gloriosa* and *Y. recurvifolia* at moderate intervals, *Y. angustifolia* in the spaces as a sort of groundwork, and an outside row of the more approachable *Y. filamentosa*. In the warmer localities *Cordylina indivisa* may be associated with the *Yuccas*. Propagation may easily be effected by lifting an old clump and dividing it. The growths should be potted singly and placed in a warm house for a few weeks, afterwards gradually hardening them off and planting in their permanent positions. The fleshy roots if cut into lengths and placed in a propagating frame will soon break and produce plants much in the same manner as the tropical *Dracenas*. A. C. BARTLETT.

*Pencarrow Gardens, Bodmin.*

## INDOOR GARDEN.

### THE GREENHOUSE.

ERICAS and Epacris that during the winter have been flowering should be cut well back, and the plants afterwards should be placed where they can be given air in abundance and be syringed to encourage them to break freely. Genistas in the same way require to be pruned well back, and if they are syringed and given air as required they will soon begin to grow strongly.

#### AZALEAS

immediately they have done flowering should be given attention. The plants at this time exhibit symptoms of exhaustion, and require some effort to stimulate them to make growth. This is not the best time to repot them; if potted now they would fail to grow with any degree of satisfaction, and would not flower with equal success another year. In a temperature of 55° to 60°, and with syringing two or three times daily, they grow freely, and should be assisted with manure liquid in a diluted form and a light dressing with Clay's Fertilizer.

#### DAPHNE INDICA RUBRA,

so delightfully scented, is by no means an easy plant to grow. The soil in which we find it to thrive best is yellow fibrous loam, to which add a very little fibrous peat and a few finely broken up potsherds, and pot moderately firm. The use of large pots is a mistake, but they should be well drained and given a dry airy atmosphere, and if occasionally a weak dose of soot water be applied to the roots—but not of newly-potted plants—the foliage will assume a dark green colour.

#### LIBONIAS FLORIBUNDA AND PENRHOSIENSIS

are gems when well grown for flowering during the winter months. These are free-rooting plants, and

should be repotted annually in two parts fibrous loam to one of leaf-soil, with a little dried cow manure added. When repotted the plants do not always require to be given a larger pot. They will not suffer any check if with care a good deal of the old soil is shaken away from the roots, and they can then be returned to the same sized pot, or in some cases be placed in pots a size smaller. The present is a capital time to insert cuttings.

#### PELARGONIUMS.

Regulate the growth of the plants by removing a few of the shoots that are weak and useless, and stake and tie into position those that are to flower. Whilst stimulation to growth is often effected by the liberal use of sulphate of ammonia, nitrate of soda, &c., it is doubtful whether the plants when given such stimulants flower so well as those that are fed with manure liquid, guano, or Clay's Fertilizer. J. P. LEADBETTER.

*Tranby Croft Gardens, Hull.*

## FRUIT GARDEN.

### BANANAS.

THESE are very useful as a change in dessert and much appreciated, especially if ripe fruit can be procured at this season of the year. *Musa Cavendishii* is the species most generally grown in England, and this is more easily managed so as to give ripe fruit at a time when other choice fruits are scarce. Some growers prefer growing them on in pots, and in giving them one or two shifts before planting out in tubs or borders. I have always obtained much better results without this extra labour. Where plants are grown in beds suckers are always plentiful, while those grown in tubs generally throw up one or two strong suckers by the time the fruit is ripe. Remove the suckers when small and plant direct into the fruiting tubs, about 2 feet square, from which fairly good results can be obtained. Allow plenty of drainage, and use good fibrous loam, a fifth part of wood ashes and rotten manure, and a good sprinkling of bone-meal. Keep a night temperature of 65°, and allow the house to run up to 90° with sun-heat, the house being frequently syringed and damped down to keep up a moist atmosphere. Be careful not to give much water to the plants until they are well established, after which they should be liberally supplied with diluted liquid manure. Plants grown in beds produce the finest fruit. It is not necessary to remove all the soil more than once in three years if the drainage is good. Remove some of the old soil, and top-dress with the above soil. Select suckers in good positions at intervals of two or three months, and repeat the top-dressing when well rooted through. In the summer months when the plants are growing fast or swelling their fruit it is almost impossible to over-feed them. No bottom-heat is required, but plenty of heat and moisture; a quick and healthy growth, and good results can thus be obtained.

#### VINE PROPAGATION.

Vine eyes started as advised in previous calendars will now be well rooted through, and should be moved into 5-inch or 6-inch pots, returning them again to bottom-heat or a shelf over the hot-water pipes. If they are required for planting out this season this must be done before the roots become matted, or they should be shifted into larger pots. Pinch out the lateral at the first leaf, and carefully water until rooted through. Give a night temperature of 65° and the usual rise from sun heat. Syringe them moderately and keep a moist atmosphere. Cut back vines. Those required for fruiting in pots next season will now need shaking out and repotting, using clean 12-inch pots. Give the vines a little bottom-heat if possible, and keep the house moderately moist and a little closer until they are well established. Use good fibrous loam, a sixth part of old lime-rubble and wood-ashes, and a sprinkling of bone-meal and soot. Give the canes plenty of light and train near the glass to encourage short-jointed growth and plump buds, keeping the laterals pinched to one leaf, as for vine eyes.

*Impney Gardens, Droitwich.*

F. JORDAN.

KITCHEN GARDEN.

THE new month, true to its bad reputation, has opened all over the north with severe frost, 16° being registered here on the morning of the first. Should this be repeated for long serious damage must accrue to fruit-buds that, owing to the mild winter, are in an advanced state of growth. It will be well to see that plenty of protecting material is kept at hand. Protection must still be afforded to roots in the ground, and at night coverings applied to Cauliflower, Lettuce, &c., wintering in cold frames. Rhubarb has made rapid growth during last month, and should now have some loose straw drawn over the plants. Peas through the ground or just planted out should be carefully protected while this cold lasts. In early mornings advantage (while the ground is hard) should be taken to prepare all plots still to be dug by wheeling on manure and removing all refuse.

SEED POTATOES.

The stock of these should now be looked over and cut ready for planting. If it is intended to plant any new varieties they ought to be procured at once, as prices are rapidly rising. The main crop should be chiefly well-tried varieties suitable to the district.

TOMATOES.

Plants raised from seeds sown early in January will now be ready for another shift. Five-inch pots will be ample. The potting material should consist of most part good loam with a sprinkling of

syringe constantly applied, and should they become infested they ought to be removed at once.

GENERAL REMARKS.

Brussels Sprouts, Cauliflowers, Onions, &c., growing under glass must be kept as cool as possible, and if the plants have made two good true leaves they should be removed to cold frames, keeping them close to the glass. During this bad weather inspect all roots, &c., in the stove house. Prepare stakes for Peas, Beans, &c.

THOMAS HAY.

*Hopetoun House Gardens, N.B.*

ORCHIDS.

CYMBIDIUM GIGANTEUM WILSONI.

MESSRS. JAMES VEITCH AND SONS, Limited, Chelsea, exhibited this Cymbidium on the 23rd ult. before the Royal Horticultural Society under the above name, and it was then given an award of merit. It was imported from Yunnan, China, and has been classed by M. Rolfe as a variety of *C. giganteum*. It, however, differs from *C. giganteum* in being of dwarfer habit and having a less vigorous raceme of flowers. The sepals and petals are green, spotted with

at the base of last season's growth. From those that were repotted last season in most cases simply remove some of the surface material to allow resurfacing with fresh compost. Good plants in small pots will be benefited by giving them more pot room for further development. The reverse should be done to those that have deteriorated; the smaller the pot a weakly plant is in the better it can be managed. The necessity of cutting away the back bulbs, or nearly severing the rhizome in the case of those that have good healthy eyes at the base, should be kept in mind. Pots should be used for their culture, giving a good drainage. I prefer one or two crocks, over which place some chopped rhizomes. It is essential to treat each plant separately as to how much drainage should be afforded. A well-rooted plant does not require as much as another with little or no root. In the latter case the pot should be nearly half filled. A good compost consists of two parts each of fibrous peat and chopped sphagnum, with one part of good Oak leaf-soil, well mixed together with some small broken crocks and coarse sand.

GENERAL REMARKS.

With lengthening days and stronger light the temperatures in the different houses may be raised a few degrees and kept in a humid growing state whenever the outside conditions are favourable. If the night temperature outside is low the houses must be drier at night. Strong sunshine is now often followed by cold winds and sharp frost at night, causing the temperature to fall very rapidly directly the sunshine is gone. The fires should be started early enough in the day to counteract this rapid fall. One very often finds a higher temperature in the morning than was the case the preceding evening. This is wrong, and very harmful to the plants. The temperature should gradually fall from 3 p.m. to 6 a.m.

Odontoglossums, Cymbidiums, and Cypripediums will now benefit by overhead syringing

CYMBIDIUM GIGANTEUM WILSONI. (Natural size.)

on bright days, yet for some time this should be done early enough in the day to allow of their becoming dry before night. Admit air freely whenever the outside temperature is favourable. It will be necessary to lower the blinds during the brightest part of the day on most of the Orchid houses. Now and in

bone-meal in it. Place the plants on a shelf near the glass, a temperature of about 60° being the most satisfactory.

FRENCH BEANS.

Those sown in January are now showing flower in abundance, and while they are still in bloom syringing must be discontinued. As soon as the fruits are set weak liquid manure should be given. Another good sowing should be made now, choosing a reliable variety. Growth will now be much more rapid, so the pots ought to be placed near the glass as soon as sown. Beans growing in Melon or Cucumber houses should be carefully watched for the appearance of red spider and the

brown, while the lip and throat are white, heavily marked with reddish brown. Perhaps upon further examination this Cymbidium may be given specific rank; at any rate, so far as growth and flowering are concerned it is quite distinct.

WORK FOR THE WEEK.

CATTLEYA LABIATA.

RENEWED activity is evident in many plants, so it will now be time to take in hand the requisite repotting, &c. It is a good plan to pick them out for repotting when new roots are being emitted

the late summer season temporary is preferable to permanent shading painted on the glass, yet, even where blinds are used, it is generally necessary to paint some glass. I find a mixture made of flour and water very good. If the glass is clean when it is applied it generally stands the season, and when no longer required it is very easily removed. *Gatton Park Gardens, Reigate.* W. P. BOUND.

SOPHRONITIS GRANDIFLORA. — There were few brighter Orchids among the fine display of these flowers in the Drill Hall recently than *S. grandiflora*; several pans of it were conspicuous in the collection from Sir Trevor Lawrence, Bart. The brilliant scarlet flowers are most invaluable now.

## BOOKS.

**Flora and Sylva.**—The March number contains clever illustrations of the new annuals *Tridax gaillardoides* and of *Magnolia parviflora*, both by Mr. Moon. There are several wood engravings, including a very beautiful one of *Nepenthes picturata* and one of "An Old Tree of the Eastern Plane," whilst the articles comprise descriptions of the Almonds, the Sassafras tree, the Wych-Hazels, and the Hepaticas. The following extracts are of great interest to garden lovers:—

## "TRIDAX GAILLARDIODES.

"There are only some seven or eight plants bearing this name, nor have they ever attracted much notice, being for the most part uninteresting members of the vast family of Composites. There are, however, two kinds which have recently found a place in gardens—one known as *Tridax bicolor rosea*, a pretty tender annual with uncommon flowers of rose and yellow; the other, *Tridax gaillardoides*, forming the subject of our coloured plate. This new plant is an introduction due to Messrs. Dammann and Co. of Naples, and is said to come from California, the other species being mostly from Mexico. Through no fault of culture these Central American plants are not always well flowered in this country, our climate rarely bringing their rich colouring to perfection. This plant, however, is said to be very free in its flowers of vividly contrasted white and gold, which are borne throughout the summer upon stems 18 inches to 2 feet high. It should be planted in light, warm soil and in an open and sunny spot, the seed being sown in gentle heat, and the young plants treated as other tender annuals. The pretty contrast in colour and their length of stem make the flowers useful for cutting.

## "PLANTING WIND-SWEPT SHORES.

"The merit of the Monterey Pine (*P. insignis*) as a shore tree is well seen at Bodorgan, in Anglesea, where many trees are in rude health within a few yards of the sea. There is nowhere a more wind-tortured shore, judging by the appearance of the few stunted native trees in the open land, but planting of an effective kind has been done almost on the seashore. At the water's edge are the Sea Buckthorn, Furze, and Barberry, which first bar the south-western gales and winds, and a few paces within these rows of Pines and Evergreen Oaks appear, and soon, with the aid of these excellent shore trees, almost any kind of evergreen planting may be carried out. The whole place is most instructive as regards planting near the sea. The contrast between the wind-swept surface of the island and the noble avenue of evergreen trees leading from the lodge to the house is very striking. Such planting, however, can only be carried out well where we plant a wood and not a mere belt, the trees in the massed wood protecting each other better than any artificial shelter that could be devised. Into such a wood the wind may tear fiercely, but is soon tamed down to something like gentleness.

## "RIVERSIDE COLOUR AT STRAFFAN.

"At Straffan, Kildare, yesterday (February 16), the spreading masses of Snowdrops under the red-twigged Lime trees on the lawn gave quite a beautiful effect. They are on the lower lawn below the flower garden, and are occasionally flooded as the Liffey overflows, but this only seems to increase their vigour. Just at this season, however, the most harmonious colour at Straffan is of the crimson Dogwood and red Osiers alongside the now full-flooded river, and extending from the island to the great bridge below. No words could give anything like an adequate idea of the soft and varied shades of colour, not alone of the planted banks themselves but of their still more soft and delicate reflections in the water below. This well-wooded river scene at Straffan shows how simply and naturally most cheerful and ever-varying winter effects of colour may be obtained, and especially, as in this case, near water. This river scenery from Straffan Bridge is luckily seen by

many, as the Kildare hounds meet or pass there often during the hunting season, and it certainly affords a lesson in planting for winter colour of an impressive kind, showing that some of the strongest and best effects obtainable in our home scenery are also easily obtainable by simple means.—F. W. BURBIDGE."

## MICHAELMAS DAISIES.

**D**URING the past few years some very pretty and distinct varieties have been added to the Aster. The only disadvantage in planting them in the garden is that some spread so rapidly that they soon overgrow surrounding plants, or when planted in a bed together the weaker-growing soon have to give way to the stronger. It is chiefly those of the *Novi Belgii* type which should be planted with caution, though some of these are among the most showy, and where space can be given few things make a better effect in a mixed border, they will grow well in any soil and under conditions not favourable to most plants. They do not root down deep into the soil, and are liable to suffer from drought, though this has not been the case this season. The wet summer has at least been favourable to them, and many of them have grown far beyond the height usually given in describing them. To keep them properly under control they should be divided and replanted annually, or at least once in two years. This applies particularly to the strong-growing sorts, or those which spread so freely by underground rhizomes. In the following list I have divided them as much as possible according to the habits of the various sections.

In some it is easy to attach them to a particular species, while others of distinctly hybrid origin it is difficult to place under any section. *A. acris* is very distinct, it forms a dense tuft of growth from the base, but does not spread; it is dwarf, and produces dense masses of pale blue flowers, with narrow, drooping petals; *A. carnea*, a small-growing variety with bluish-tinted flowers; *A. linearifolius*, similar to the type, but taller and having very narrow leaves.

*A. Amellus* is another decided species with little variation except in time of flowering and shades of colour. The best of these are *Onward*, deep purple-blue; *Framfieldi*, pale blue; *Stella*, mauve; and *Distinction*, mauve, with a decided pink shade. I may mention that there are two varieties under the last name, but it is Mr. Davis's variety that is referred to, and it is very scarce in the trade. The *Amellus* varieties rarely attain to more than from 18 inches to 2 feet high, and form dense masses of large, showy flowers.

*A. Novae Angliæ* is another distinct section with large, showy flowers. The best of these are *Mrs. J. F. Raynor*, bright rosy red, one of the most distinct of all the Asters, and should be in every collection; *Ryecroft Pink*, similar, but of a paler shade; *Pulchellus*, deep purple; and *Precocité*, blue-purple, flowers early. These grow from 3½ feet to 4½ feet high, form dense masses, but do not spread. They should be divided annually.

*A. cordifolius*.—In this section there is considerable variation. Some spread in the ground rapidly, others grow close. They are from 4 feet to 5 feet high, and have large, cordate leaves at the base, tall, slender branching flower-stems, and mostly very small flowers. The plants are light and graceful in habit, and are general favourites, particularly *Diana*, *elegans*, and *albus*, and to these may now be added *C. profusus*, a new variety with larger flowers of a soft blue-mauve.

*A. ericoides*.—With these may be included *vimineus* and its varieties, and some which are put with *diffusus*. There are also several among the new varieties which are of the same dwarf-branching habit, and should be included in the same group. Of the new varieties *Delight*, *Freedom*, *Thora*, and *Enchantress* are very attractive, being dwarf and compact, the long, branching racemes densely covered with tiny flowers. The true *A. ericoides* is of more erect growth, with

long, slender branches covered with small white flowers; *A. densiflorus* is dwarf, and with very pretty Heath-like foliage. Those more properly belonging to *A. diffusus* have a coloured disc. *A. horizontalis* forms a spreading bush about 2 feet high with dark stems and foliage, bluish pink flowers with an almost purple disc; *Coombe-fishacre* is one of the best and most distinct, grows about 4 feet, the long, spreading branches covered with soft bluish flowers of medium size. The Hon. Edith Gibbs may be included in this section. The flowers, which are of a pale mauve or French grey, are produced in great profusion on long, spreading racemes, which droop down to the ground. *Osprey* is another promising new variety of similar type, with pink flowers, which change to a darker shade. *Triumph*, a seedling from *Coombe-fishacre*, of more erect habit and larger flowers, deep pink, with a light centre, is another good addition; and *Brightness*, which comes from the same parentage, is a very pretty pink variety of erect and rather close habit; *Vimineus perfectus*, very compact, growing white, with dark disc, a very distinct and pretty variety.

*A. Novi Belgii*.—This is the most extensive group we have, and includes many widely distinct and showy varieties, varying in height from 1½ feet to 5 feet or 6 feet. All that properly belong to this section spread rapidly underground, and in some the rhizomes run out a great distance. Taking the tall-growing sorts, *Margaret Mathews* and *John Wood* are the best whites; *Robert Parker* and *Top Sawyer*, pale blue; *W. Marshall*, mauve; *Autumn Glory*, deep blue; *Calliope*, bluish pink; and *Lilacina*, lavender-blue. All the above have large flowers, and make tall, spreading bushes. From those of medium height I should select *Candida*, white; *Cottage Maid*, mauve, with a rosy tint; *Arcturus*, deep blue; *Daisy Hill*, bluish mauve; *Floribundus*, blue, with a purple shade; *Nancy*, clear blue, one of the very best; *T. S. Ware*, mauve, tinted with red; *Rosy Gray*, French grey; *Proserpine*, bluish, with a mauve tint; *Maiden's Blush*, soft bluish pink; *May Crum*, medium-sized white, starchy flowers, light, branching habit, one of the best for cutting from; this has grown taller this season; *Jessie Crum*, of same habit, with lavender-blue flowers; *D. B. Crane*, blue-mauve, with a slight rosy tint, large flowers, produced in dense corymbs; and *Evening Star*, mauve, with a distinct rosy shade, free-branching habit. From those of dwarf habit I should take *lævigatus*, dense growing, with small pink flowers; *Mrs. Peters*, white; *Esme*, white, large flowers; and *Densus*, lavender-blue. Of others which spread freely *paniculatus* may be mentioned; *p. laxus*, soft grey-mauve flowers, of medium size, on long, loose sprays, growing from 2 feet to 3 feet high; *p. W. J. Grant*, a very distinct variety, flowers flesh pink, with dark disc, produced in long, drooping sprays, height from 3 feet to 4 feet.

*Punicus* is a distinct species. The best variety is *pulcherrimus*; it has large silvery grey flowers in long pyramidal spikes 4 feet to 5 feet high; *grandis*, a new variety of similar habit, with pure white ray florets and yellow disc; *turbinellus*, pale blue-mauve, flowers on long, slender stems, is a very distinct species, growing about 3 feet high; and *albus*, the white variety, differs only in the colour of its flowers.

*A. Tradescanti* is a late-flowering species, small flowers, white, with yellow disc, tall, branching habit, growing to 6 feet high.

*A. trinervis*, another distinct species, with terminal branching corymbs of pale mauve flowers, 2½ feet to 3 feet high.

*A. macrophyllus*, large basal leaves, erect, branching flower-stems, small mauve flowers, medium height.

*A. corymbosus* and *A. stellatus*, dwarf habit, with spreading corymbs of starry white flowers.

Many more desirable species and varieties might be added, but I am afraid I have already occupied too much space. The collections shown at the Crystal Palace on October 6 and 7, and those at the Drill Hall on October 13, gave a good idea of the beauty and variety to be found in these useful autumn-flowering hardy plants. A. HEMSLEY.

ST. LOUIS EXHIBITION.

BRITISH ROYAL PAVILION AND GARDEN.

**N**EXT May at St. Louis will be opened the "World's Exposition," which will doubtless prove to be the largest exhibition that has yet been seen, eclipsing, as it does, in magnitude and beauty of the buildings and the extent of the grounds the wonderful exhibition at Chicago in 1893, and those held at intervals in Paris. The exhibition is well advanced towards completion, and, judging from illustrated accounts, it will be all that the Americans say about it. Besides the great buildings set apart for collections of international exhibits, it is customary in American exhibitions to erect isolated buildings as special pavilions from the various States, and each foreign country builds a pavilion characteristic of its native architecture, and surrounded by a garden also characteristic of the style peculiar to it.

There will be at St. Louis pavilions erected by Great Britain, France, Germany, Austria, Italy, and other European countries, China, Japan, and other Eastern countries, as well as from the South American Republics. Great Britain will be well represented in its section, and the Royal Commission appointed last year, with the Prince of Wales as its head to represent this country, comprises a representative body of our leading men.

The Royal Commission, in its selection of a characteristic existing building in England for its Royal Pavilion, made choice of an interesting type. It was felt that the Banqueting Hall or Orangery of the Royal Palace of Kensington would be very representative of English domestic building at one of its happiest periods, and would be a tribute to the memory of a great architect, Sir Christopher Wren, to whom, after Inigo Jones, we owe the distinctly English development of the Renaissance of Italy, by which the Gothic and Tudor methods of building had been superseded. From this master's hand there was the wide choice of St. Paul's, Greenwich Hospital, and the many fine city churches; but in the Orangery of Kensington was found a building that could be strictly reproduced to its real size. With dignity and fine proportion it unites a pleasant homeliness and simplicity peculiarly belonging to English work. They forthwith commissioned Messrs. Ernest George and Yeates as architects to reproduce a replica of this building, which is of red brick and white stone, and 170 feet in length.

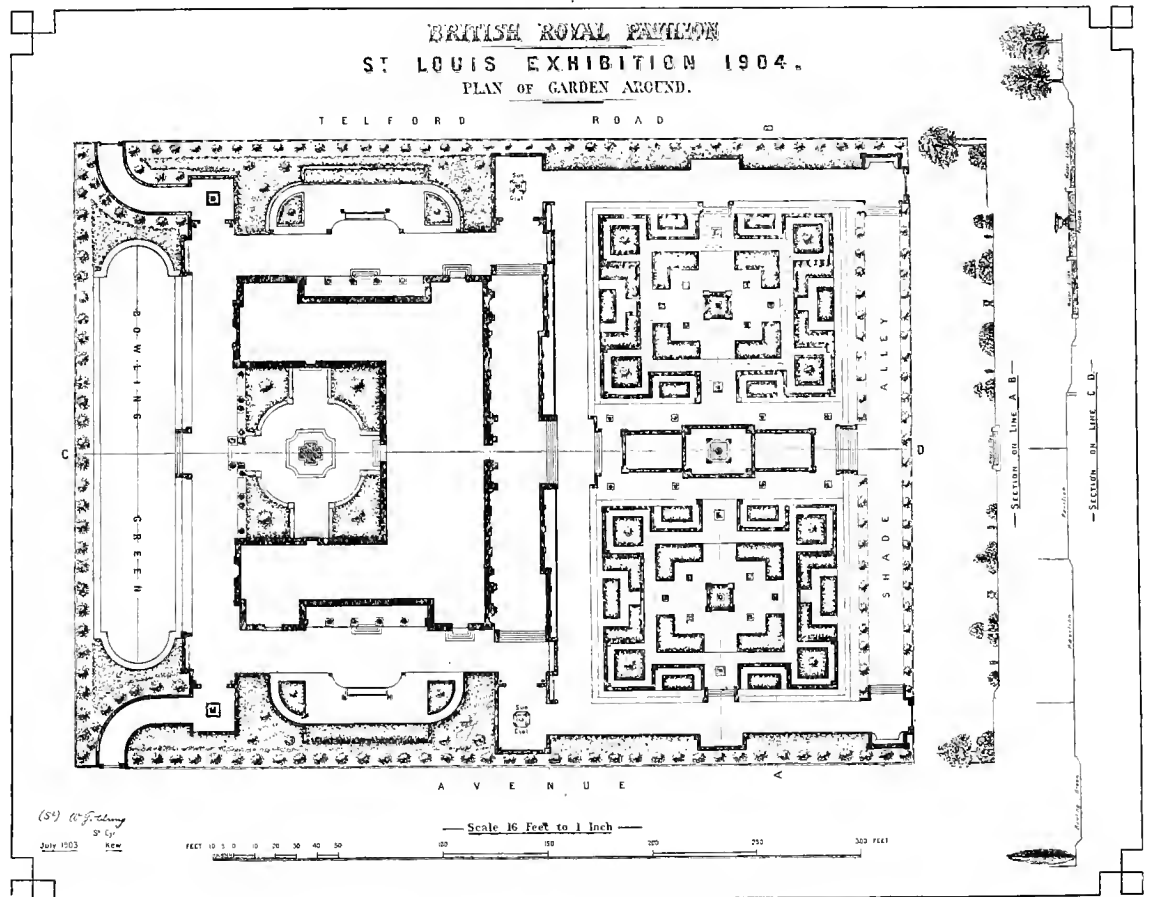

In the replica at St. Louis of Wren's building, the only departure from the original is the introduction of an enriched plaster ceiling such as would be found in a house of the period; the Orangery was left bare and white-washed. On the south side of the building is

a stone-paved terrace of corresponding size, and on this, no doubt, royal groups have gathered above the quaint parterres, clipped Yews, fountains, lead statues, and other departed glories of Queen Anne's favourite garden. The work of building the pavilion was carried out by Messrs. Trollope and Sons of London.

Mr. W. Goldring of Kew was appointed by the Royal Commission to design a garden to harmonise in character with the building, and he adopted in his plans a modified form of a garden of the period at which the Banqueting Hall was built. In the garden surrounding the pavilion an attempt has been made to reproduce on a small scale the style of garden that was generally attached to the mansion residences in England during the reigns of William III. and Mary, about the latter part of the seventeenth century, and at the time of

fashion became established and general throughout the country. The Dutch landscape gardeners whom William engaged to carry out his ideas were soon followed by numerous noteworthy English practitioners in the art, so that during Queen Anne's reign a great impetus was given to this Dutch style throughout the country, to be followed later by a school of landscape gardeners opposed to the Dutch ideas of design, and in consequence many of the finest examples of the Dutch style of gardens were destroyed, to give place to what was termed the "natural" style, in which formality and straight lines were substituted by irregularity.

The Queen Anne gardens were a pleasing combination of the Tudor, Jacobean, and Dutch styles. Their characteristic features were stately terraces, shady avenues (or "pleached alleys," as they were called), formal parterres

PLAN OF GARDEN. (Reduced from original.)

Scale of plan above about 100 feet to 1 inch. Description on line from C to D: Bowling green (sunk 1 foot 6 inches), shade trees behind; terrace (20 feet wide), with statues at end, surrounded by Yew hedges; pavilion; inner court, with fountain and Palms; terrace (24 feet wide by 100 yards long), with sundials at ends; fountain (90 feet long by 25 feet wide), centre basin 1 foot 6 inches above side basins; pleached alley of shade trees, raised 3 feet above general surface; flower garden panels on each side of fountain (120 feet by 100 feet), sunk 1 foot 6 inches below general surface, and 3 feet below south terrace. Design of panels outlined by clipped dwarf evergreen hedges; centre of panels of turf, paths around beds of paving stones.

Queen Anne in the early part of the eighteenth century. Previous to this period the large English mansion gardens were mostly in the Tudor style, and continued so during the troublous times of the Stuarts; and many a fine garden as well as house suffered at the ruthless hands of the Commonwealth leaders.

William Prince of Orange brought over Dutch ideas of gardening, and it was he who introduced what was then, and has since been termed, "Dutch gardening." He introduced this style of gardening about the Royal residences, and it was not long before the

enclosed by hedges clipped into shapes and embellished with topiary work, the forms of animals and birds cut out of Yews and Box. This topiary work was distinctly the special introduction from Holland, and was at the time considered to be the highest form of art in the garden. The fashion became a craze, and was carried out to such an extent that it came under the scathing ridicule of Pope, and after that declined. There are, fortunately, still some of the most noteworthy examples of these Queen Anne gardens preserved in England, and the tendency at the present time

is to continue the style, and a decided reaction has set in against the style of "imitation" of Nature.

There is a charm about a genuine old formal garden that appeals to most people, and the idea of such a garden is shown in the British Royal Pavilion Garden, formed in six months, though the matured example would require six generations to perfect. A water-basin and fountain were always associated with an old garden, and generally the bowling-green and pleached alley were as inseparable from it as were stone and lead statnes (often bad), and lead urns and vases, which were generally admirable, though the making of these seems to be a lost art nowadays. The long borders of old-fashioned flowers appeal to everyone in England, and the large beds of simple outlines are more in vogue than the embroidered parterres in the Italian style, that do not accord with the present prevalent practice of massing harmonising groups of colour.

The work of carrying out Mr. Goldring's plans was entrusted to Mr. T. W. Brown, formerly of the Royal Gardens, Kew, and subsequently superintendent of the gardens of the Emperor of Morocco at Fez, and he has carried out the work well under the disadvantages of restricted time and a severe winter climate.

The material for planting the garden beyond the trees and hedges has been contributed by the various firms in England, the chief exhibitors being the following: Messrs. Cannell and Sons, Swanley, hardy herbaceous plants and seeds; Messrs. J. Carter and Sons, High Holborn, bulbs and seeds; Messrs. J. Cheal and Sons, Crawley, Dahlias; Messrs. Cutbush and Sons, Highgate, specimens of topiary work, clipped Yews, Box, &c.; Mr. J. Forbes, Hawick, Phloxes; Messrs. Hobbies, Limited, Dahlias; Messrs. Kelway and Sons, Langport, Gladioli, Delphiniums, and other plants and seeds; Mr. Amos Perry, Winchmore Hill, hardy herbaceous plants; Messrs. Sutton and Sons, Reading, Gladioli, Lilies, Narcissi, and other bulbs.

## KEW NOTES.

### INTERESTING PLANTS IN FLOWER.

#### Temperate House.

ACACIAS in variety, *Beschorneria tubiflora*, *Calpurnia aurea*, *Clematis indivisa*, *Corylopsis pauciflora*, *Eriostemon affinis*, *Illicium floridanum*, *Kniphofia longicollis*, *Rhododendron grande* and *Strelitzia Reginae* and variety *citrina*.

#### Palm House.

*Talacima Candollei*.

#### † Range.

*Asarum macranthum*, *Carazuata cardinalis*, *Centradenia floribunda*, *Dimorphotheca cuneata*, *Eranthemum graciliflorum*, *Feijoa sellowiana*, *Freesia Armstrongii* and *F. kewensis*, *Hypolytrum bananum*, *Jatropha podagrica*, and *Lachenalia convallarioides*.

#### Orchid Houses.

*Amblostoma cernuum*, *Cattleya Trianae*, *Cypripedium argo-spicerianum*, *C. Dauthieri albino* var., *C. rothschildianum*, *Dendrobium aureum*, *D. crassinode*, *D. findlayianum*, *D. Juno*, *D. luteiflorum*, *D. luteolum*, *D. Madonna*, *D. nobile*, *D. n. var. cooksonianum*, *D. n. var. pulcherrima*, *D. n. var. sanderianum*, *D. primuminum*, *D. Rolfe*, *D. splendissimum*, *D. wardiano-japonicum*, *D. wardianum*, *Eria stricta*, *Goodyera procera*, *Laelia lindleyana*, *Masdevallia triangularis*, *Maxillaria picta*, *M. sanguinea*, *Platclinis latifolia*, *Phaius Blumei*, *P.*

*grandifolius*, *P. Wallichii*, *Saccolabium violaceum* var. *harrisonianum*, *Selenipedium Titanum*, *Spiranthes tortilis*, and *Stelis tristyla*.

#### Greenhouse.

*Arum palestinum*, *Clianthus puniceus*, *Clivia miniata*, *Eupatorium petiolare*, *Hippeastrums* in variety, *Kennedyia prostrata*, *Pentapterygium serpens*, *Senecio Petasites*, forced bulbs and shrubs, and many other things.

#### Alpine House.

*Anemone blanda*, *Coptis orientalis*, *Corydalis bulbosa*, *C. kolpakowskyana*, *Crocus candidus*, *C. biflorus* var. *Pestalozzæ*, *C. Sieberi*, *C. versicolor*, *Hyacinthus azureus* var. *robustus*, *Iris reticulata*, *Primula denticulata* alba, *Saxifraga Albertii*, *S. burseriana*, and *S. burseriana major*.

## NOTES FROM THE MARKETS.

**H**EATHS.—*Erica persoluta* alba is on sale; *E. wilmoreana* is much better flowered than those seen earlier; *E. fastigiata*, which is not so well known, is a useful Heath; and *E. hyemalis* is holding out. On Saturday, the 5th inst., there were some small plants, well flowered, on one stand. The trade for Heaths through the season has not been very encouraging to growers, and Acacias, Boronias, and other hard-wooded plants also find less favour than formerly. In conversation with a grower we were told that if he had to depend on Covent Garden he would have to give up growing all hard-wooded plants. There is still some good nursery trade for them, but for London florists' work they find very little favour.

*Hardy deciduous flowering shrubs* are general favourites, but we do not see many that are really well done in the market. A few good Lilacs are seen, also *Pyrus* and double *Prunus*. *Azalea mollis* is not over plentiful, but some well-flowered plants are seen. *Rhododendrons* are also coming in, but with the early forced plants the flowers are rather small. *Genistas* are very plentiful, and on some stands some beautifully flowered plants are seen, but they do not sell so well as might be expected. Splendid Persian *Cyclamens* are plentiful, and sell fairly well. *Azaleas* continue plentiful; the bright colours sell best.

*Hyacinths* are still numerous; growers can hardly make a profit on these after deducting the cost of the bulbs. Tulips are also abundant; the samples vary considerably, and the best sell well, but many have to be cleared out at very low prices. All cut bloom is plentiful, and there is a little improvement in trade. White *Azaleas* seem quite out of favour; the short stems are much against this. Anyone starting with young plants and growing them on vigorously might find it pay to cut with the longest stems possible. Frequently *Azaleas* do not get treated liberally enough when they are making growth. Liberal supplies of manure may be given with much advantage, but it is only while growing that it should be applied.

*Liliums* continue plentiful, the longiflorums being particularly good. Lily of the Valley, both in pots and cut, is very good, but prices are rather low. *Gardenias*, *Eucharis*, and *Pancratiums* are also below average prices. The supply of English *Roses* continues to increase. Of reds, *Liberty* and *General Jacqueminot* are good; the former makes the highest prices, but the older favourite sells well. *Catherine Mermet* and *The Bride* are good.

*Carnations*.—There is now a good supply, and several growers have the American varieties in good form. A great variety of *Daffodils* is now in, and some of the best sorts are now to be seen. The supply in the French market was much below that of the previous week, and prices went up fully 50 per cent. on good stuff.

## THE FERN GARDEN.

### HARDY FERNS.

**S**INCE hardy Ferns are only now commencing to think of the growing season, and it will be some weeks yet before definite activity will commence, it is as well to anticipate their waking up by profiting by their dormancy to repot, replant, and divide whenever it is necessary. Last season's fronds are still to the fore in the evergreen species, and whatever is green and alive should be left intact, while what is brown and obviously dead can be removed. Out of doors, however, it is as well to leave the old fronds alone until the end of March, as they act as great protectors should those drying winds set in which are sometimes characteristic of the month. Ferns in pots should now be examined, and if in any way out of condition it is well to shake them out, remove any soured soil which will possibly be the cause of their weakness, and also any accumulation of old dead roots, and repot them in fresh soil, a compost consisting of good yellow loam and brown fibrous peat or leaf-mould in equal proportions, lightened with a liberal sprinkling of coarse silver or road sand. Plants in good health but which have formed many crowns of the shuttlecock type, such as *Shield Ferns*, *Buckler Ferns*, and *Lady Ferns* should be divided, since they show to much greater advantage when single crowns are grown than when several are bunched up together, fighting for dear life with each other and with their fronds intermingled as well as their roots. The fronds of a single crown plant will grow about twice the size of those produced by one of a mob, and also if it be a choice variety, plumose or crested, which is the kind we have in view as we write, will display its character much more thoroughly. We may mention here that it is the fine varieties only that we advise to grow. The common British Ferns, which are hawked about the streets or bunched up in boxes outside nurserymen's shops, are absolute weeds in the eyes of the connoisseur of British Ferns, and if seen at all in his collection are only grown to complete it and as contrasts to those far more charming forms to which these weeds have given rise by sporting. To effect the division aforesaid, the plants are best lifted, when it is easily seen that the side shoots are practically independent plants, with roots as well as fronds of their own, and as a rule a blunt instrument inserted behind them will easily force them off when the roots can be disengaged from the general mass, and the Fern is ready for planting. Where as in some cases the main crown has divided, the separate centres, if a neck exists between them, can be forced or cut apart, taking care not to pinch them, and so form independent specimens. Ferns with travelling rootstocks like the *Polypodies* look best as established specimens, and should be grown in pans instead of pots, thus giving them an opportunity of spreading. If division be desired or propagation in quantity, every piece of the travelling rootstock with a growing tip, a frond or two, and some rootlets will form an independent plant. A number of the choicest varieties of *Shield Ferns* (*Polystichum*), especially the plumose ones, have a knack of forming little bulbil plants an inch or so up the frond stalk on the inside, and it is as well when removing the fronds to look for these and instal them with a bit of the stalk in little pans, when they will root and in time give new specimens. These kinds often are nearly barren of spores, so that this forms almost the only way to propagate them, and in any case much time is saved, and, moreover, it is fairly certain that the plants will come quite true. This is also a good time for the cleansing of pots and pans and generally putting the fernery in order, since the least possible damage now results to the future growth, and as the old fronds have run their course a little damage to them is immaterial. It is, however, not advisable to remove green fronds as it impoverishes the plant. In repotting a good look out should be kept for worms and grubs of all kinds.

CHAS. T. DRUERY, F.L.S., V.M.H.

## RIVIERA NOTES.

**IRIS PALÆSTINA** has improved so greatly this second season that it is worth mentioning as an admirable contrast and companion to *Iris reticulata*. The spreading green leaves and creamy flowers of *Iris palæstina* become most effective when in contrast to the spiky growth and deep rich colouring of *I. reticulata*. Being of the *alata* section it may not be hardy everywhere, but as it flowers so much later than *I. alata* it is well worth a trial in combination with *I. reticulata*. In this climate it needs no care when once planted, but it prefers a strong soil. The double *Sparmannia* is in great beauty this winter. Its heads of double white flowers are so soft and round they almost remind one of the Guelder Rose; its pale green leaves are often too large and too abundant, and in England it has a bad reputation for not flowering. No doubt the heat and drought of last autumn ripened the wood very fully, but the secret of success is, I think, to keep it to a single stem as much as possible, and if it does not flower the first year it will undoubtedly do so the second, when it makes a branching head. The common Lilac has often much the same fault; if you let the suckers grow there are plenty of leaves but not much flower, while if you keep the Lilac to a single stem it flowers abundantly after the first or second season. Certainly when in abundant flower the beauty of the double *Sparmannia* is a thing to remember, and is worth a little trouble.

**PRUNUS DIVARICATA** is out almost as soon as the Almonds, and it is decidedly hardier. The white of its small blossoms is so cold that it makes one think of "Blackthorn winter," which (in a measure) reaches us here when the *Acacia dealbata* is in full flower, some time or other during the month of February. Well known in England, it is not often seen here, and perhaps it is more valuable in the north than with us. How beautiful a double form of it, like the double Blackthorn, would be.

**ERICA MEDITERRANEA HYBRIDA**, which has a flower like *E. carnea* on the growth of *E. arborea*, is a plant for the north as well as the south. It is only now getting well known here, and in the future it should be as indispensable to the shrubbery as *E. carnea* is to the flower garden in winter. The very best and most useful things are often neglected at first, as in this case, but after a time, when once its beauty is developed, it should be as universally grown as the *Laurustinus*, and give an added charm to the early spring garden. It stands pruning remarkably well, and might even be employed as a hedge, where its cheerful lilac sprays of blossom would contrast well with *Forsythia* and other early spring bloomers behind it. The colder weather of the last week has suited the fine form of

**MEGASEA LIGULATA**, commonly grown here under trees, where nothing else can thrive, and I note with surprise that the forms I brought out from England, thinking them to be superior, are, on the contrary, not to be compared, either for size or colour, to that grown here for many years. It will be interesting to see if another season alters this state of things, for I find that plants are much affected at first by the change of soil and climate, some very favourably, and others quite the reverse.

The fragrant *Iris olbiensis* is now thrusting up its flowers among the bent grass and grey Rosemary on the bank. Its deep purple petals are a charming contrast to the cloud of pink Peach

blossom above; the yellow form is, curiously, quite a month later, as if it preferred to wait for the brown leaves of the young Cherries that expand at the same time. Undoubtedly there are natural affinities among plants, and I have often wondered what plant or tree is the natural companion of *Acacia dealbata* in its native country, Australia, for here its intense brilliancy of colour (yellow) sneers somehow with its surroundings; it is too garish and hard, in spite of its lightness and grace, yet I doubt not that in Nature all is harmonious where it flowers by the water-courses of its own home.

**CYCLAMEN LIBANOTICUM** has now proved itself to be one of the very prettiest of its race. In the wild garden a tuft or two of it among *Anemone blanda* (both the white and the blue forms of which bloom together with it) make as dainty a group as can well be imagined. I do not see any seedlings from it, which makes me fear there is something wrong, but it is so particularly neat and attractive in habit, form, and colour that I hope I never may be without some of it. Not even the giant Persian *Cyclamen* makes a more beautiful group, for *Cyclamen libanoticum* carpets the ground with its leaves and flowers in the neatest and most attractive fashion, while the massive *Cyclamen persicum* is rather apt to be lax and straggly when left to Nature.

Nice.

EDWARD H. WOODALL.

## THE KITCHEN GARDEN.

## THE SUTTON RHUBARB IN SPRING.

**A**T this time of year the early Rhubarb is much appreciated, and this variety is a great acquisition on account of its earliness, colour, and excellent flavour. This season, owing to the scarcity of Apples, there is a greater demand for this plant, and the variety named forces so readily that it is more useful for that reason. For many years I grew the Early Red or Royal Albert, but it does not equal the variety noted above; of late years more interest has been taken in this plant, as several really good additions have been placed before the fruit committee of the Royal Horticultural Society, and though some are not yet in commerce they will be most valuable for early supplies. Even the one named above is not very plentiful, and doubtless, like the Potato, it needs much time to work up a good stock, and when lifted for forcing there is a certain waste. This variety possesses other advantages. It is a beautiful colour when forced or grown in the open, a bright rich red, which remains even when cooked. The sticks are large, and it is not unlike the well-known *Victoria*, but more upright in growth, earlier, and seeds very little. It is well worth growing by the side of the old sorts, as then its better quality will soon be noted. It gives a heavy return in good soil.

S. H. B.

## FORCING SPINACH IN SPRING.

In many gardens, especially those in low-lying positions, it is difficult to get good supplies of Winter Spinach from December to May. I am aware that there is the Beet Spinach, but the quality is not equal to the round-leaved or prickly. It may be thought unnecessary to force Spinach, but I do not think so, as in some places the demand is great, and, if possible, it is well to meet it. By sowing seed now the spring crop may be hastened considerably, and at a small cost of labour. Few vegetables raised under glass plant out better than Spinach. Seed sown now in small pots in rich soil, and given cold frame shelter for a time, may be planted out in a few weeks, but it is necessary to thin the seedlings, three to five plants in a pot being ample. I have also sown broadcast in a movable frame, and got a much earlier supply.

All, however, cannot spare glass to finish the crop, but grown thus it is not long about, and some varieties grow much quicker than others. I prefer the Carter, a very large-leaved variety, the leaf being more solid, a dark green colour, and of quicker growth than the well-known *Victoria*, the last named being much superior to the old round-leaved variety.

G. W.

**Iris germanica in flower.**—In one of the greenhouses at Sir John Thornycroft's pleasant Thames-side garden at Chiswick this beautiful plant is in flower, three days earlier than last year. The successful system responsible for such a satisfactory condition has been already described in these columns.—*Quo.*

**Sales of Orchids.**—Those interested in Orchids should not fail to visit Messrs. Protheroe and Morris's rooms on Fridays. There are always some good things to be seen, and they may often be secured at very moderate prices. On Friday, the 4th inst., some beautifully flowered plants of *Dendrobium wardianum* were sold at from 2s. to 3s. 6d. each, which was not the value of the blooms. Smaller plants of the variety *Lowi* made from 5s. to 10s. each, a low price for such a fine variety. A fine piece of *Odontoglossum Loochii* made £5. Two good plants of *Cattleya trianae alba* were sold, one making £5, the other £3. A nice piece of *Dendrobium Hildebrandti* made £3 3s. Some beautiful pieces of *Odontoglossum crispum* in flower went very cheap; one extra good variety went up to £1. Some of the newly-imported Orchids sold fairly well.

**Begonia semperflorens gigantea.**

A group of this shown at a recent meeting of the Royal Horticultural Society, though not sufficiently developed to be seen at its best, was sufficient to show what a desirable *Begonia* it is for flowering at this season. It is by no means a novelty; indeed, it is less grown now that it was a few years ago, being perhaps somewhat eclipsed by the numerous *socotrana* hybrids; but most of them are over before the new year is far advanced. While *Begonia semperflorens* is in itself a very variable species, the variety at the head of this note, as well as two or three others, were obtained by the intercrossing of that species with the Mexican *B. lynchiana*, which was first distributed about twenty years ago under the name of *B. Roezlii*. It is a tall-growing species of sparsely-branched growth, but with clusters of bright-coloured blossoms. It was a happy thought of M. Lemoine, of Nancy, to cross it with *B. semperflorens*, the result being seen in the variety at the head of this note, which in general appearance greatly resembles a deep-coloured form of *B. semperflorens*, but is much larger in all its parts. It is in winter and early spring that the flowers are most valuable, and at that time a group forms a very ornamental feature in the greenhouse or conservatory. In growing this *Begonia* there must not be too much stopping, as the weighty clusters of blossoms are at their best on stout, vigorous shoots. This variety is often to be seen in good condition in No. 4 greenhouse at Kew.—*H. P.*

**The Hepatica at home.**

To see the *Hepatica* in its native beauty one should see it upon the southern slopes of the Alps, where it is one of the mountain plants that creep nearest the Mediterranean wherever the hills approach the sea. Its favourite haunt is in woods of Oak, in which it is sheltered from the summer glare and yet freely exposed until its season of flower is past, while in autumn the falling leaves drift thickly into the nooks and crannies loved of the plant, providing Nature's own shelter and also food. With the first genial days of spring their buds begin to expand, until in March and April, when the snow has gone and the sun is hot at noon, the tufts of colour spread as a vast sheet of blue in every tone and shade, forming a dense carpet throughout the belt of woodland, varied here and there by clumps of wild *Narcissus*, by pallid *Asphodel*, or quaint wild Orchids, and mingling with *Primroses* and the pale blue Italian *Scilla*. Without stirring more than a few yards it is possible to fill a sack with roots, if minded to enjoy their beauty nearer home. A great green lizard pops up over a stone to see

what the stir is about, and at long intervals a peasant goes by on his mule, whose spreading panniers brush the growth beside the narrow track, while in his wonder at your occupation the rustic almost forgets to give you his good-day. But for the rest one is in a world of blue: the bluest of blue skies overhead, a blue haze upon the further hillsides, in the distance the deep dark blue of the Mediterranean, and around and at one's feet that all-pervading azure tapestry.—*Flora and Sylva*.

**A Tree Savin.**—The Savin is variable in growth and habit, several forms being grown in gardens, such as the horizontal, prostrate, and Tamarisk-leaved varieties. There exists, however, another form, which of late years has caused discussion among botanists. This shrub has for many years been grown by M. Jordan under the name of *J. Sabina Villarsii*, and it is thus mentioned by Villars in his "Histoire des Plantes de Dauphine (1789)": "We have a tree-like form at Saint-Clement, near Embrun;" the plant still exists in the same neighbourhood. This Tree Savin is also found around Grenoble, at Mount Saint-Eynard, the Casque de Neron, and the rocks of Comboire. In the department of Hautes Alpes it occurs as stated at Saint-Clement, and probably elsewhere in the district. This tree should be of value to growers of pyramidal Junipers. It is rare in gardens, growing rather slowly, and bearing berries of deep bluish black.—VIVIAND MOREL, *Lyon Horticole*, in *Flora and Sylva*.

**Calliandra Tweedii.**—This, though the best-known member of a large family, is quite uncommon, yet for brilliancy few stove plants can compare with it at this season when the flowers are developed. It is a native of Brazil, and forms under cultivation a freely-branched bush, with slender shoots clothed with pretty bright green divided leaves, a good deal in the way of some of its relatives, the Acacias and Mimosas. The flowers, which are borne in crowded heads, are small, except for the clusters of long, prominent stamens, which stand out like tufts of crimson silk. This constitutes the showiest portion of the inflorescence, and at a little distance suggests some of the members of the Myrtle family, such as the Callistemons, Melaleucas, *Metrosideros*, &c., to all of which the term Bottle Brush trees have at one time or other been applied. This *Calliandra* will grow freely with the treatment given to the general run of stove plants, but in order to flower it well the wood must be thoroughly ripened during late summer and autumn, to ensure which the plants should at that period have all the sunshine possible. It was introduced from Brazil in 1840, and though so attractive just now and not at all difficult to strike from cuttings, I have sought for it in vain in the catalogues of several nurserymen.—T.

**Polygala dalmaisiana.**—This is one of the hard-wooded greenhouse plants that still retain a certain amount of popularity, no doubt owing to the fact that effective specimens may be grown in comparatively small pots. It is of rather loose growth, the shoots being clothed with ovate leaves about 1 inch in length and somewhat glaucous. The flowers, which are borne in clusters at the points of the shoots, are a bright rosy purple colour, with a curious brush-like cluster of stamens. This *Polygala* is a native of the Cape of Good Hope, and to succeed in its culture it needs a compost made up of two parts peat to one part loam and a liberal sprinkling of sand. The little hardy *Polygala Chamæbuxus*, a delightful rockwork plant, belongs to the same group.—H. P.

**Freesia Armstrongii.**—This *Freesia*, recently noted as being in flower at Kew, has been known some years, but even now it is very uncommon, and cannot be obtained from the usual trade sources. In growth and general appearance it resembles a vigorous form of the popular *Freesia refracta alba*, but it differs markedly in the colour of its blossoms, which are of a pleasing shade of deep pink, particularly towards the edges of the segments. Another feature is the total absence of the perfume which adds much to the popularity of *F. refracta alba*. *Freesia Armstrongii* is named in compliment to Mr. W. Armstrong of Port Elizabeth, who found it wild, and, I believe, first sent it to Kew. A second and very pretty species (which,

like *F. Armstrongii*, is scentless) is *F. aurea*, which, though not a new plant, has only been generally seen within the last two or three years. This, which is rather dwarfier than the others, bears rich golden-yellow flowers. Like the rest, it is a native of South Africa, and in some districts it occurs in great profusion.—H. P.

## SOCIETIES.

### ROYAL HORTICULTURAL SOCIETY.

#### DRILL HALL MEETING.

There was an excellent display of plants and flowers at the Drill Hall on Tuesday last. Orchids were very finely shown. The Orchid committee awarded one first-class certificate and three awards of merit to new Orchids. There were numerous groups of forced shrubs, hardy plants, Primulas and other greenhouse flowers, Ferns, &c., although no awards to new plants were made by the floral committee. The fruit committee is having no work at all this spring. There was only one dish of Apples put before them on Tuesday, at the previous meeting there was no fruit at all, and at the penultimate meeting one dish of Pears only. The Drill Hall was crowded both morning and evening.

#### ORCHID COMMITTEE.

Present: Harry J. Veitch, Esq. (chairman), Messrs. James O'Brien, J. Gurney Fowler, James Douglas, Walter Cobb, H. Ballantine, Norman C. Cookson, de B. Crawshaw, Jeremiah Colman, H. T. Pitt, J. Charlesworth, W. A. Bilney, Richard G. Thwaites, A. A. McBean, F. W. Ashton, E. Hill, F. J. Thorne, T. W. Bond, E. Sander, M. Gleeson, J. W. Odell, W. Boxall, H. H. Young, H. A. Tracy, W. H. White, Francis Wellesley, H. Little, and J. Wilson Potter. Baron Sir Henry Schröder, Bart., The Dell, Englefield Green (gardener, Mr. Ballantine), showed some choice and splendidly flowered Orchids, for instance, *Dendrobium leechianum*, *D. wardianum*, *D. heterocarpum album*, *D. hybridum*, *D. Dulce*, *Cypripedium lathamianum*, *C. Calypso* Oakwood var., *C. mastersianum*, *C. macrochilum*, *Calanthe Baron Schröder*, *Lycaste Skinneri* alba, *Odontoglossum crispum* Mrs. H. G. Moon, O. Coradinei, O. Adriane, and O. *Memorie Victoria Regina*. Silver-gilt Flora medal.

Jeremiah Colman, Esq., Gatton Park, Reigate (gardener, Mr. W. P. Bound), exhibited a group of choice Orchids, the plants finely grown. *Cymbidium Lowianum*, *Odontoglossum crispum roseum*, O. *ruckerianum*, O. *triumphantum*, *Platyclinis glumacea*, *Phaius Norman*, *Cattleya Schoderi*, *Acineta Colmanii*, all evidenced the best of culture. *Masdevallia courtauldiana*, *Cypripedium niveum*, *Dendrobium Othello* Gatton Park var., *Ceoloyne cristata leoniana*, *Brassavola nodosa grandiflora*, and others were well shown also. Silver Flora medal.

Messrs. James Cypher and Sons, Cheltenham, showed some excellent *Dendrobiums* in many varieties, as well as other Orchids. Among the *Dendrobiums* were *D. barbatulum*, *D. nobile nobilium*, *D. n. sanderianum*, *D. n. statterianum*, *D. Backhousei*, *D. jamesianum*, and *D. Apollo* album. *Cypripedium Maudici*, *C. villosum giganteum*, *C. lathamianum*, C. Charles Richmond (barbatum X bellatulum), *Miltonia vexillaria*, *Sophranitis grandiflora*, and *Laelia jozheana* were also shown by Messrs. Cypher. Silver Flora medal.

The group of Orchids from Messrs. Sander and Son, St. Albans, contained *Dendrobium nobile nobilium*, *Cymbidium hookerianum*, C. *eburneum-lowianum*, *Trichopilia suavis* var., *Holetia brucklehurstiana*, *Laelio-Cattleya blechleyensis*, *Maxillaria venusta grandiflora*, *Chysis Chelsoni*, *Zygopetalum crinitum*, *Laelio-Cattleya Edwardii* (*cinabarina* X *hardyana*), *Laelia harpophylla*, *Epidendrum decandolleana*, *Odontoglossum crispum Mariei*, *Zygopetalum crinitum*, and *Ceoloyne lactea*, all Orchids of exceptional attractiveness. Silver Flora medal.

Messrs. Charlesworth and Co., Heaton, Bradford, Yorks, exhibited a group of Orchids, in which hybrids of much beauty were conspicuous. The brilliant apricot-red of *Laelio-Cattleya Charlesworthii* made a bright patch in the centre, while *L.-C. Doris* (soft apricot sepals and petals), *Laelia Bristis* (lemon yellow with purple lip), *L.-C. Myra* (primrose, with purple lip), *L.-C. Myra Etoile d'Or* (rich yellow), and *Oncidium concolor* were all of striking colours. *Cattleya Enid magnifica*, *Laelio-Cattleya haroldiana*, *Lycaste Skinneri Fascinator*, *L. S. Exquisite*, and *L. S. Fairy* were also very handsome. Silver Flora medal.

R. G. Thwaites, Esq., Chessington, Streatham, exhibited a large display of Orchids, consisting largely of *Dendrobiums*. Some of the best were *D. nobile murhinianum*, *D. n. virginale* (raised from seed), *D. Wiganiae*, *D. Euryalus Apollo*, *D. Cybele elegans*, *D. wiganianum album*, *D. Isis*, some *Cattleyas*, and *Odontoglossums*. Silver Flora medal.

W. Thompson, Esq., Walton Grange, Stone, Staffs, showed some handsome seedling *Odontoglossums*, such as O. *Adriane* var. *Babette*, O. *Vuystekei*, O. *waltoniense* (*crispum* X *polyanthum*), and O. *crispum-harryanum*. Silver Banksian medal.

Messrs. Hugh Low and Co., Enfield, had a handsome group of *Dendrobiums*; for instance, *D. Boxalli*, *D. crassinode*, *D. rubicinctum*, *D. wardianum*, *D. nobile ballianum*, *D. roeblickianum*, as well as *Oncidium concolor*, *Ceoloyne cristata alba*, *Sophranitis grandiflora*, *Angraecum citratum*, *Cypripedium Helenii*, and *C. hirsutissimum*. Silver Banksian medal.

Captain Holford, C.I.E., Westnort, Tetbury, Gloucester (Orchid grower, Mr. Alexander), showed *Odontoglossum Adriane* var. *Lady Crawford*, *Dendrobium Clio Burford* var., *Ada antirrhata Westnort* var., and *Cypripedium Scipio*. Messrs. William Bull and Sons, Chelsea, showed *Laelio-Cattleya Myra*, *L.-C. Myra pallida* (a beautiful form, with pale primrose sepals and petals and crimson-purple lip), and *Cypripedium Boxalli* var.

*Laelia jozheana* var. and *Cypripedium villosum* X *Niobe* were shown by F. W. Wellesley, Esq., Westfield, Woking.

A cultural commendation was given to *Leptotes bicolor*, shown by Walter Cobb, Esq., Dulcote, Tunbridge Wells (gardener, Mr. J. Howes). Mr. Cobb also showed *Odontoglossum Adriane cobbianum* and a hybrid *Cypripedium*.

H. T. Pitt, Esq., Stamford Hill, N. (gardener, Mr. Thurgood), showed *Dendrobium aggregatum majus*, very finely flowered (cultural commendation), a very dark-flowered *Lycaste*, and *Liparis purpurea*.

De B. Crawshaw, Esq., Rosefield, Sevenoaks (gardener, Mr. W. J. Stables), showed *Odontoglossum crispum de Barri* and O. *X waltonense rosefieldense* (*crispum* X *polyanthum*).

A cultural commendation was given to Sir Trevor Lawrence, Bart., for *Dendrobium Luna*, very finely flowered. Messrs. James Veitch and Sons, Limited, Chelsea, showed *Cypripedium Harri-leaanum* (*harrisianum superbum* X *leeanum superbum*) and *Laelio-Cattleya Myra*.

Norman C. Cookson, Esq., Wylam-on-Tyne (gardener, Mr. H. J. Chapman), showed *Dendrobium nobile* X *Wiganie* and *D. X McJap* (*McArthie* X *japonicum*).

C. J. Lucas, Esq., Warnham Court, Horsham (gardener, Mr. G. Duncean), showed *Laelio-Cattleya warnhamensis*.

Lord Rothschild, Tring Park (gardener, Mr. E. Hill), showed *Phalenopsis intermedia* Postell.

#### NEW ORCHIDS.

*Laelio-Cattleya haroldiana magnifica*.—A very fine form of this hybrid *Cattleya*, whose parents are *Laelia tenebrosa* and *Cattleya hardyana*. The lip is large, handsome, and of rich velvety purple colouring, and the soft red-purple petals are unusually broad. Other forms of this hybrid have previously been certificated. From Messrs. Charlesworth and Co., Heaton, Bradford. First-class certificate.

*Odontoglossum crispum Rosendate* var.—A well-formed flower, the white sepals and petals and lip heavily marked with chocolate-red. The edges of the lower sepals are tinged with purple. From J. Wilson Potter, Esq., Park Hill Road, Croydon (gardener, Mr. W. H. Young). Award of merit.

*Odontoglossum crispum Kintesianum*.—Of unusual and somewhat curious appearance. The sepals are white, except for a tinge of lilac, while the petals, which point slightly upwards, are heavily marked with brick-red. From Norman C. Cookson, Esq., Wylam-on-Tyne (gardener, Mr. H. J. Chapman). Award of merit.

*Dendrobium Melanodiscus* var. *gloriosum*.—This is a handsome and improved variety of a good *Dendrobium*. The sepals and petals are tinged with deep rosy purple. The throat is maroon-coloured, margined at the mouth with a band of rich yellow, followed by a band of white, and finally the lip is tipped with purple. From Mrs. Haywood, Woodhatch Lodge, Reigate (gardener, Mr. C. J. Salter). Award of merit.

#### FRUIT COMMITTEE.

Present: George Bunyard, Esq. (chairman), Messrs. J. Cheal, T. W. Bates, S. Mortimer, W. Pope, Horace J. Wright, H. Markham, J. Willard, James H. Veitch, R. Lewis Castle, H. Parr, F. Q. Lane, J. Lyne, G. Norman, A. H. Pearson, W. Poupert, and Owen Thomas.

A dish of apples, shown by Messrs. Vokes, Kingsworthy, Winchester, was the only exhibit before this committee.

#### FLORAL COMMITTEE.

Present: W. Marshall, Esq. (chairman), Messrs. H. B. May, R. Deao, J. F. McLeod, R. W. Wilson-Ker, F.S.A., Charles T. Drury, John Green, James Hudson, J. Jennings, William Howe, Charles Dixon, W. Bam, J. A. Nix, C. J. Salter, Charles E. Pearson, Charles Jefferies, H. J. Cutbush, R. W. Wallace, William Cutbush, Charles E. Shea, W. P. Thomson, Harry Truett, George Paul, J. W. Barr, E. C. Notcutt, E. H. Jenkins, R. Froebel (visitor), Edward Mawley, R. Hooper Pearson, C. R. Fielder, E. T. Cook, George Nicholson, C. Bick, and George Gordon.

An excellent group of Ferns from Messrs. J. Hill and Son, Edmonton, included *Platycerium*, such as *P. Veitchii*, many *Davallias* and *Adiantums*, several fine *Eymnogrammas*, *Woodwardia orientalis*, *Adiantum asarifolium*, and the very distinct *Pteris internata*. The group included many good and useful things, all well grown and well arranged. *Adiantum Weigandii* is a very distinct form. Silver Flora medal.

The alpine and hardy plants from Messrs. Cutbush and Son, Hightate, included *Megaseas*, *Iris reticulata*, *I. Heldreichii*, *Saxifraga apiculata*, *Shortia galicifolia* and its variety *rosea*, *Epigaea repens* full of bloom, the pretty yellow *Lithospermum canescens*, the hybrid blue *Primroses*, the vernal *Gentian* in flower, some charming masses of *Hepatica*, &c. *Rhododendron chameacis* was very beautiful. Messrs. Cutbush also showed *Tree Carnations* and a fine lot of forced shrubs—*Prunus*, *Wistaria*, *Azalea mollis*, *Laburnums*, *Cytisus Adamii*, *Guelder Rose*, *Ribes*, and the like, with *Palms*, *Aralias*, and other things interspersed. Silver-gilt Banksian medal.

Messrs. B. S. Williams, Holloway, also set up a group of forced shrubs. *Lilacs* in plenty, *Azalea mollis*, *Palms*, *Viburnums*, *Guelder Rose*, and the like. Silver Banksian medal.

Messrs. Cheal and Sons, Crawley, had the blue *Primroses*, *Ericas*, *Soldanella alpina*, and various *Primulas* with rock shrubs in a rockery arrangement.

Mr. R. Anker, Addison Road, Kensington, had miniature examples of *Cacti*, *Aloes*, &c., together with pots of *Trifolium repens pentaphyllum*, &c.

Messrs. William Bull and Sons, Chelsea, showed *Azalea indica*, *variegata*, and others. All the plants were a mass of bloom.

An interesting exhibit of catkin-bearing plants from Lord Aldenham, Elstree, included *Garrya*, several species of *Alnus*, with *Corylus* in several forms, and the large *Populus alba canescens pendula*. A most interesting lot. Vote of thanks.

Ferns, with *Gardenias* and *Boronia*, were comprised in the exhibit from Mr. H. B. May, Edmonton. Of the former *Pteris Childsii* was notable, and with *Davallias* and *Adiantum farleyense* gave a freshening look to the whole. *Gardenia florida*, as pot plants, and *Boronia megastigma* were very attractive. Silver Banksian medal.

# THE GARDEN

No. 1687.—VOL. LXV.]

[MARCH 19, 1904.

## DESTRUCTION OF BRITISH FLOWERS.

IT was well that the Rev. Professor Henslow, at a recent meeting of the Horticultural Club, drew attention to the wholesale destruction of the British flora, and urged Parliamentary action to protect rare and even familiar flowers from extermination. A sort of protection exists over the fauna of Britain, though the Act is seldom enforced, in spite of the many misdeeds committed by the mercenary and thoughtless; but flowers may be dug up and destroyed with impunity. All who love their gardens, and therefore the flowers in them, must possess sufficient zeal in the interest of wild flower life to bring the law into force for its protection. It is always the thoughtless that are the most blameworthy, but the collector who is determined to stamp out a species for the sake of boasting that his herbarium contains the last of a flower that has gemmed many a wild corner with its beauty for generations is despicable. This selfish motive is revealed not by the plant collector alone, but also by those who collect butterflies and birds' eggs. It was mentioned that the pretty larger Butterwort (*Pinguicula grandiflora*) was almost extinct, one colony known to a speaker at the meeting having disappeared in a year through this idiotic and senseless desire to skin the English counties of their flower life.

The collector who is anxious for knowledge and specimens for his herbarium or garden takes sufficient for his purpose without reckless disturbance of the roots. Those who search hill and dale in this spirit acquire a keen love for Nature generally and quicken their powers of observation. It is a health-giving pursuit which we in nowise desire to frustrate, but to destroy for the sake of acquiring a collection no one else can accumulate is nothing short of criminal. A herbarium is well enough in its way. Under proper control it is invaluable for botanical reference, as at Kew; but the true botanist has no evil intent when he attempts to form a representative collection of British flowers; he knows the way to lift a plant or any portion of it, with no intention of blotting it from the British flora.

Many common Ferns are rapidly becoming extinct; they are grubbed up in cartloads from the lanes of Devonshire and other well-favoured counties and sold in the nearest markets or in Covent Garden. The plants are dragged out of the ground with or without roots, and few

survive. This is the fate of common things, and of the rare species it may be said that every year brings them nearer to total extermination.

Local guides are responsible for much mischief. The haunts of rarities are pointed out with a clearness that makes access to them as easy as to some neighbouring pleasure resort, and the result is destruction in a few summers. The visitors, filled with a desire to reproduce the local flora in their back yards, bring back handfuls for themselves and friends, and in doing so flatter themselves they are devoted to Nature in general and flowers in particular.

We hear and read much about studying Nature—a little more than we care about. The life-giving breezes of the moorlands and the restfulness of country lanes and woodlands bring ruddy cheeks to the tired workers in the towns; but all this may be enjoyed without destroying the things that give the countryside its enduring charm—the Primrose in the sheltered bank, the Cowslip in the mead, and the Dog Rose in the hedgerow. These gifts from the lap of Nature are for the pleasure of all, and not for the "Nature" societies to grasp at for the instruction of the hordes of so-called pupils, whose bent is destruction, and whose love of flowers is expressed by dissecting them to dab between bits of blotting-paper, never to see light again. If county councils wish to encourage half days in the country let the teachers first instil in the minds of their pupils that every wild flower has its message to the world. Under careful tuition the child reverences the wayside flowers, and acquires a knowledge of their names, and in time the places the botanist has allotted them in the great natural orders.

## EARLY CHRYSANTHEMUMS.

### FLOWERS FOR THE AUTUMN GARDEN.

MARKED progress has been made in recent years with the early-flowering Chrysanthemums, and the time has come when a greater variety should be introduced into English gardens. Only seventeen or eighteen years ago the Japanese varieties at that time catalogued were very few compared with what exist to-day. About a dozen good Japanese varieties were in existence, and of these not more than three or four are now in general cultivation. At that time the late M. Simon Delaux created a sensation by introductions of the Japanese type of flower. He had been working for fifteen years to achieve his purpose, and his efforts were rewarded with success. In succeeding years

new and interesting sorts were raised, and in 1890 the list had grown enormously. The greatest change, however, was effected in 1891, when M. Delaux distributed in one set 125 new varieties, the Japanese sorts being almost exclusively represented. It was impossible to deal satisfactorily with so large a number of novelties in one season, and in consequence many of the best among them were soon forgotten, though some of the original set which had been lost for years were met with in the trials at Tamworth in 1902 and 1903.

In the years immediately subsequent to M. Delaux's great achievement English raisers of seedling Japanese varieties were also at work. So successful have been their efforts that the French and other Continental raisers are left entirely behind. English raisers have been wise enough to select the better varieties for hybridising, and in consequence many beautiful sorts have been added. Mme. Marie Masse, a lilac-mauve Japanese variety, introduced in 1894, was the beginning of better things. From this variety have sprung many delightful novelties. To begin, it developed no less than four sports—cream, chestnut, cerise, and yellow—and there are already quite a number of beautiful seedlings in cultivation from the same sort. It is for the garden that these plants are so welcome. They are sometimes described as hardy outdoor Chrysanthemums, and though this description is not strictly accurate, when generally applied to the section it is perfectly correct respecting a large number of the plants, and especially so of Mme. Marie Masse and its sports. This group has a branching growth, and single plants will carry from 100 to 150 flowers. When left to grow naturally the plants are seen to better advantage. Pinching back or stopping the shoots is quite unnecessary with the early sorts, and far more satisfactory results are seen when the plants, except for staking and tying, are left to develop naturally. The constitution of this ideal family of plants is strong and robust, and no matter how severe the winter may be they come through the ordeal apparently unharmed. They are truly perennial, and should be in all lists of hardy plants. Flowering time begins in late August and continues throughout September and October, and in mild seasons, such as last autumn, the display continues well into November.

The early Chrysanthemums create brilliant effects. The smallest plants, if planted towards the end of May, will make handsome bushes by the flowering period. Many of our readers may remember the trial of early-flowering Chrysanthemums at Chiswick in 1897. "They made a magnificent display," the *Journal of the Royal Horticultural Society* states, but those sorts are completely eclipsed by those of to-day. The newer race shows great variety, both in the colour and form of the flowers. The warm colourings of the early Chrysanthemums succeed the summer's

display, thus prolonging the brightness of the garden for a month or two longer. They are essentially for the outdoor garden, as their vigorous root action, when once they get established, demands greater space than pot culture affords. Although we have referred almost exclusively to plants of Japanese origin, the pretty Pompons must not be forgotten. Progress has been slow in this section; still, there have been several decided gains of late years. The newer sorts are distinctly pretty, and deserve more extended culture.

There is a tendency to crowd the plants in the border. Allow plenty of room, as well-grown plants give a greater wealth of flowers than those crowded together.

## NOTES OF THE WEEK.

### FORTHCOMING EVENTS.

March 22.—Royal Horticultural Society's Drill Hall Meeting.

April 5.—Royal Horticultural Society's Drill Hall Meeting.

April 8.—Truro Daffodil Show (two days).

April 12.—Brighton Horticultural Show (two days).

**Royal Horticultural Society.**—The next fruit and flower show of this society will be held on Tuesday next in the Drill Hall, Buckingham Gate, Westminster, 1—5 p.m. A lecture on "Heredity of Acquired Characters" will be given by the Rev. Professor G. Henslow, V.M.H. At a general meeting of the society, held on Tuesday, the 8th inst., fifty new Fellows were elected, amongst them being Sir Henry Pottinger, Bart., Lady Lyall, and Lady Slacke, making a total of 351 elected since the beginning of the present year.

**Sale at the Royal Horticultural Society's Chiswick gardens.**—The auction sale held on Thursday, the 10th inst., indicates that these interesting gardens will soon disappear. Favoured by a bright sunny day there was a large attendance, but many were there simply to take a last look at the old place. One could not help thinking that much useful horticultural work might yet be done in such a large, open space, but the place already begins to bear a dilapidated appearance, the houses, which at one time were so well filled with collections of useful plants, being almost empty. The old Fig trees (occupying what was once the Palm house), with their gaunt and naked appearance, looked as if they belonged to past ages. Buyers for these were not numerous, and the prices realised did not come up to expectations. Other fruit trees found very few buyers, there being scarcely any competition in the bidding. Some things sold very well, the *Yucca recurvifolia*, of which there were a good many fine plants, bringing quite a lively competition, 95s. for ten plants being the highest price noted. Some of the Palms sold very well. The large Camellias in the entrance also found several buyers. The prices paid were not high, but the cost of moving will add considerably to the auction price. Some of the large specimens were bought for Kew.

**Chicory as a spring vegetable.**—This is not much grown as a forced or spring vegetable in this country, but on the Continent it is in great favour as a salad. I would advise a trial of the large variety, the Witloof, which should be boiled in the same way as Seakale, and served hot. The flavour may not be much relished at first, but it soon becomes palatable; indeed, to many who have lived abroad it is much esteemed. On the other hand, when grown for use in this way I do not mean the loose, long leaves one often sees when used as a salad, but the close, compact growth from 4 inches to 6 inches long, with a rather thick base; indeed, very much like Seakale cut in a young state. When Chicory is used in this way it requires simple culture, and may be started into growth in any dark place with a temperature of

50°. Of course, the growths vary according to the roots, but if seed is sown in the spring and ample space given to the plants they will make excellent forcing material for next season. The roots are not unlike a large Parsnip, and they are very hardy, but in exposed situations they are lifted and stored. This is not necessary in well-drained soil, and a few roots placed indoors every fortnight from November till April will give a supply. I have noticed that large quantities of this plant are sent from abroad in the condition I have referred to for using as a vegetable, the variety being the Witloof or Large Brussels, but as its culture is so simple it is well worth growing as a spring vegetable.—G. WYTHES.

**Bulb-growing at Nairn, N.B.**—Although on a comparatively small scale, the show of bulbs held in connexion with the spring flower show and industrial exhibition of the Nairn Seamen's Society on the 9th inst. deserves some notice. A feature is made of Hyacinths, and, although the number on exhibition was smaller than last year, it was stated that a much greater number than formerly had been cultivated in the dwellings of the fishermen. The bad weather had been against them coming forward. Those shown were of excellent quality. The leading awards were: Silver cup, for best Hyacinth in the show, Miss Ellen, Union Street; best blue Hyacinth, Mrs. Cope, Park Street; white Hyacinth, Mrs. M'Pherson, Harbour Street; red, J. Cameron, Wellington Square.

**The National Sweet Pea Society—Provincial prizes.**—The committee has arranged with the Wiltshire Horticultural Society, whose exhibition will be held on August 10, to include in the schedule a special class for Sweet Peas, for which the National Society will provide the prizes. The class is identical with the audit class on page 19 of the National Sweet Pea Society's schedule, and all members of this society may compete free, others on paying the usual fees of the Wiltshire Society, of which Mr. Leonard Sly, Salisbury, is the secretary. The total prize money offered by the National Sweet Pea Society is £3 2s. 6d. and a silver medal to the winner of the premier place. Mr. Sly will send full particulars. The society has also been able to arrange with the Galashiels Horticultural Association for a class on behalf of northern growers, the prizes being identical with those offered in the previous case. The class here is similar to the classification class on page 19 of the National Sweet Pea Society's schedule, and it will be contested on September 10. Members of the National Sweet Pea Society are entitled to exhibit free of special entry fee. The secretary of the Galashiels Horticultural Association is Mr. James Mallen, Galashiels, who will be pleased to send complete details of the class.—HORACE J. WRIGHT.

**Tree Ferns in Glasgow Botanic Gardens.**—Within recent years much has been done to make the Glasgow Botanic Gardens more worthy of the great city to which they belong, and, without sacrificing their usefulness to the students who frequent them, to render them more attractive to the public at large. The establishment is a fine one, handicapped although it is by the atmosphere of the city, and the recent changes have done much to improve it in every way. One of its features is the Kibble Palace, a noble glass structure, which is being improved by the substitution of better plants for the more common ones it formerly contained. A wonderful improvement has been effected by an alteration in the roof of the central portion, so as to admit more light, and by planting under it a group of Tree Ferns, arranged in a strikingly natural manner among rocks. This has been skilfully done. Those who have visited these splendid plants in their own habitats are among those who praise the Kibble Palace group the most. There are among them some noble Dicksonias and others, but it is in the skill of the grouping that the main charm consists. Certainly this is one of the many successes Mr. Whitton has had in the course of his work in the Glasgow parks.

**The Departmental Committee** appointed by Lord Onslow to enquire into and report upon the fruit industry of Great Britain held

sittings on the 9th, 10th, and 11th inst. The following members were present: Mr. A. S. T. Griffith-Boscawen, M.P. (chairman), Colonel Long, M.P., Mr. C. W. Radcliffe-Cooke, Mr. Hodge, Mr. Mouro, Mr. Vinson, Dr. Somerville, Mr. P. Spencer Pickering, the Rev. W. Wilks, and Mr. Ernest Garnsey (secretary). On the 9th inst. Mr. W. W. Berry, Mr. Edward Pink, Mr. John Wood, and Mr. George Smith, as four Kent growers; on the 10th inst. Mr. John Riley, Mr. John Watkins, and Mr. J. H. Wootton, as three Hereford growers; and on the 11th inst. Mr. W. J. Lobjoit and Mr. W. Poupert, as two Middlesex growers, gave evidence. In addition, on the 11th inst. Mr. J. Struthers, C.B., of the Scotch Education Department, and Mr. Buckmaster, of the Board of Education, gave evidence.

**Persian Cyclamens at Farnham Royal.**—A house of Persian Cyclamens in the nursery of Messrs. W. James and Son, Farnham Royal, Slough, is bright with colour. The varieties are set out in groups to give effect to the various colourings, which pass from white to deepest blood-red, and we have never seen finer individual blooms, the petals having a look of strength without any tendency to coarseness. Many plants were so burdened with flowers that the leaves were almost hidden. There is beauty, too, in the foliage, which is sometimes a pale green, but frequently finely mottled and marbled and variegated, quite as much so as in many plants sold for their leaf colouring alone. The varieties are numerous, and all selected for the freshness and clearness of their colouring, shape of the flowers, and freedom. The cherry-red is a brilliant shade without trace of magenta, a cheery colour that is pleasurable in the sunlight and when in the house for decoration; the white is as pure as driven snow, the deep crimson of quite a glowing tone, and the salmon-pink pure and distinct. It is an object-lesson in bright and beautiful colours, and an indication that only by rigid selection and careful hybridising is it possible to achieve such results. The famous Cinerarias are opening their first flowers. We shall have something to write about these in due course.

**Spring flowers at Reading.**—I had the pleasure recently of attending one of the fortnightly meetings of the Reading Gardeners' Society early in March, when the subject under discussion was "Spring Flowers." Some time before the meeting began many members were engaged setting up cut flowers and plants. When the meeting opened there was a large display of the best kinds of spring flowers, forced shrubs, Orchids, &c. It was the finest exhibit I ever saw at a meeting of a gardeners' society, and this is an excellent way to keep up interest in the meetings. I was impressed with the many side issues this society has apart from the lectures and discussions. It does a good work in connexion with the Gardeners' Benevolent Institution. One evening a year the plants and flowers exhibited are sent to the hospital. It also assists members to find fresh situations when making changes, and does other useful work. The members number nearly 300; they are to be congratulated on their thriving society.—J. CROOK.

**Edinburgh and East of Scotland Agricultural College and horticultural teaching.**—Among the subjects before a meeting of the governors of the Edinburgh and East of Scotland Agricultural College, held on the 9th inst., was the question of the horticultural class at the college. The matter arose on the minutes of the Central Studies Committee, in which it was mentioned that the subject of altering the horticultural class arrangements and restarting the agricultural bookkeeping class had been remitted to a sub-committee for consideration. It appears from the statement of the chairman, Colonel Wardlaw Ramsay, that the horticultural class was not appreciated, but it was worthy of consideration whether a permanent lecturer on horticulture should not be arranged for. This might be done for almost the same cost as the present arrangement. Ultimately the whole matter was remitted to the committee dealing with the horticultural class. As a contrast it was reported that the forestry classes had proved very successful.

**Grape competition at the great Shrewsbury show.**—It is interesting to know that the Shropshire Horticultural Society, in the great champion Grape class competition in August next, will adopt the Royal Horticultural Society's "Rules for Judging." Scale of pointing as heretofore—Muscat Grapes, black or white, eleven points maximum, and for all others, black or white, ten points.

**Eranthemum pulchellum.**—It is seldom that one meets with this lovely old plant, but where large show houses have to be kept gay during winter it is a worthy plant to grow. The colour of the flowers is an intense blue. It is not handsome, there being a stiffness about its habit which is not pleasing; but when judiciously mixed with other plants its colouring proves very effective. It is easily propagated by cuttings, which can be had abundantly from the old plants when they are cut down and placed in heat. It will be found to thrive well in the warm greenhouse. During the growing season the syringe should be generously used to keep off red spider, a pest to which it is very subject.—E. HARRISS.

**Anopteris glandulosa.**—This, the Tasmanian Laurel, is a very ornamental greenhouse shrub, which, especially when in flower, would be taken rather as a near relative of *Clethra arborea* or one of the *Arbutus* family than a member of *Saxifragæ*. It is a freely branched, somewhat upright-habited shrub, plentifully furnished with deep glossy green leaves. They are about 6 inches long, ovate, and with the edges regularly serrated. The flowers, which are borne in erect terminal racemes, are white, saucer-shaped, about  $\frac{1}{2}$  inch in diameter, and are usually at their best in March or April. It is by no means a common subject, though it can be obtained from those nurseries (now few in number) where general collections of greenhouse plants are grown, and in the favoured districts of the south-west it will succeed out of doors. In any case it well repays greenhouse protection. This *Anopteris* was first introduced from Tasmania in 1823.—T.

**Clivia miniata.**—As a foliage plant alone this is decidedly handsome, but when in addition the cluster of handsome leafage is crowned by a massive head or heads of showy blossoms it stands forth in its way without a rival. These flowers are in their turn succeeded by large Cherry-like fruits, which when ripe are of a bright red colour. By a process of selection a great improvement has taken place in the *Clivia* within the last decade or two, as the best forms now have round, well-shaped blossoms, very different from the narrow-petalled ones at one time so generally met with, while the flower clusters are also larger, and in many cases far brighter in colour. There is, however, too long a list of varietal names, as many of these garden forms approach each other very closely, even if they are not actually identical. This cannot in any way, however, be urged against the variety *citrina*. The flowers of this are of a citron yellow or straw colour. To the amateur with but a single greenhouse, as well as in gardens of great pretensions, *Clivia miniata* has much to commend it, for, given the ordinary treatment of the general run of greenhouse plants, it will do well. It is the showiest member of the genus, but *C. cyrtanthiflora* is valuable from the fact that it flowers considerably earlier.—H. P.

**Begonia gigantea carminata.**—This was well shown at a recent meeting of the Royal Horticultural Society by Messrs. J. Laing and Sons of Forest Hill, and on a recent visit to the nursery I found the plants in even better condition. It is one of those of which the male flowers do not open freely, but in a bud state the large trusses of brilliant colour are most effective. The flower stems are also of the same bright colour, and stand up well above the bright green foliage. It may be compared with the variety *semperflorens gigantea rosea*, but is deeper in colour and also of better habit. There are not too many good bright-coloured flowers just at this season of the year, and the above should prove a very useful addition. It belongs to the vigorous-growing section, which should be propagated late in the season, or any time during June or July. Three plants may be

grown in each pot, or single plants started earlier and stopped will branch out and make good bushy plants.—A. HEMSLEY.

**Fuchsia splendens.**—Introduced from Mexico in 1841, this pretty *Fuchsia* has never attained any great amount of popularity, and as far as I know it has not been used by the hybridist in the production of any of the numerous garden forms. In common with several of the original species, it well merits extended cultivation, and if required may be had in bloom thus early in the year. It is naturally of free growth, and if allowed space for its development will form a good-sized bush, though effective specimens may be grown in 8-inch pots. In this species the leaves are heart-shaped, hairy, and pale green, while the drooping flowers, which in shape more nearly resemble a *Correa* than a *Fuchsia*, are bright crimson in colour, tipped with green. In growing this *Fuchsia* it should be well exposed to the sun during the latter part of the summer in order that the wood may be thoroughly ripened. When in a temperature above that of an ordinary greenhouse it will flower early in the year, but is perhaps most effective when allowed to develop naturally in the spring. The many garden forms have to a great extent eclipsed these original species, yet some, such as *F. fulgens*, occasionally bedded out during the summer; *F. corymbiflora* and its white variety, which last was distributed many years ago by the *Chrysanthemum* pioneer, Mr. Salter, of Versailles Nursery, Hammersmith; *F. serratifolia*, *F. triphylla*, with the tiny-flowered *F. thymifolia*, and *F. microphylla*, and the distinct *F. procumbens*, are all well worth growing.—T.

## THE GARDEN TULIP.

IT is very interesting—and, perhaps, instructive—to note the craze for a certain flower, florist's or otherwise, at one period and its stolid neglect at another. The Tulipomania which raged chiefly in Holland and the Netherlands rather more than 200 years ago is well known, and even in our own time exorbitant prices have been charged for Tulips. The last catalogue I remember with the high prices attached was issued by Mr. Groom of Walworth; the highest price was £105 per bulb, and there were several at fifty and twenty-five guineas. This was in 1854, but in a year or two later all Mr. Groom's Tulips were sold by auction by Messrs. Protheroe and Morris at very low prices, and that was the last of the high prices. The Daffodil has had its turn, and now the Potato. I had sent to me recently a copy of a cheque, drawn for £300, the price of 2lb. weight of Potatoes. The dealer who bought at this price seems to have gauged pretty fairly the character of his fellow men, for he sold 1lb. of them for £160, enough to purchase a sixteen-acre field in some parts of Essex. This is not a healthy state of affairs either for Tulips, Daffodils, Potatoes, or spotted *Odontoglossums*.

At the present time the Tulip is cheap, but, although they are cheap, they are quite as beautiful, and within the means of the gardener who can afford half-a-crown for a dozen bulbs. The cottager can now have as beautiful a Tulip bed as the prince could in the years of long ago, when *Semper Augustus* sold for 5,500 florins, *Admiral Leiften* for 4,400 florins, &c. But the most curious sale was a root of *The Viceroy*; this cost two lasts of Wheat, four lasts of Rye, four fat oxen, three fat pigs, twelve fat sheep, two hogsheds of wine, four tuns of beer, two tons of butter, one thousand pounds of cheese, one complete bed, one suit of clothes, and one silver beaker. As a matter of fact, none of these varieties would stand the test of competition against any of the bizarres, byblomens, or roses of the present day. The

Tulip, like the *Carnation*, is divided into classes or sections. The bizarres are generally placed first. These have a clear yellow ground, feathered or flamed. What the fanciers term a feathered flower has the colour pencilled round the margin of the petals only. Some varieties, such as *Masterpiece*, are almost black; *Dr. Hardy* has a reddish tint. Some of them have chestnut-red and reddish maroon colours, but all of them have different shades of yellow. The flamed flowers are also marked round the margins, but the centre of the petals are pencilled or "flamed" of the same colour.

The same remarks apply to the byblomens. These have a white ground, and the colours are of different shades of purple, lilac-purple, and a few varieties quite blackish, but the purple tints are there. Roses are quite charming in their purest white ground. Some may almost be described as scarlet, but the colours vary from rose to scarlet, and it is laid on in the same way as in the other classes. "Whence are these colours derived?" someone may ask who is not yet acquainted with Tulip transformations. The Tulip fancier crosses his different varieties of flamed flowers with other flamed varieties; the feather-edged varieties with others, selecting the best both as regards form and colour. The seedlings produced will nearly all be self colours. These are termed "breeders," because in the course of years the self colour will disappear and a white or yellow ground take its place, which will be flamed or feathered. These breeders are not kept unless the base is pure and without stain. The same remark applies to the stamens. When a Tulip takes on its flamed or feathered state it is said to be rectified or broken. The colour of the breeder form will come out in the flame or feather. For instance, a bizarre breeder will have its base yellow, and the colour chestnut, red, or even dark chocolate. The byblomen breeders will have a white base, with various shades of purple, lavender, or even deep rich black-purple. The roses, as they are termed, have a white base, the petals coloured with various shades of rose and rosy scarlet. The Tulip fancier who is also a seedling raiser has the interest kept up in his flowers year by year watching and waiting for their change from the breeder to the rectified form. "How are strains produced?" is another question that may be asked.

It comes about in this wise. The self-coloured or breeder Tulips pass into various hands, and after several years of cultivation they appear in the flamed or feathered state in several collections, but not all of them are of the same standard of excellence, and the rectified flowers take the name of the garden or the individual who produced them, and become Groom's strain or the Stapelford strain accordingly.

The Tulip is sufficiently hardy to grow and thrive in the open garden anywhere in Britain, but to obtain clean blooms of the best quality some protection is needed. The leaves are brittle, and easily injured by hailstorms; the formation of the leaves is such as hold water at their base, and, if the water freezes, damage is done in that way. No flowers show to advantage if the leaves are damaged, and few suffer so much in this respect as the Tulip, for the broad, glaucous leaves are truly handsome. To save the plants in the early stages of their growth from injury, the Tulip fanciers bend iron hoops over the beds, the hoops raised about a foot or 18 inches above the beds, mats or some protecting material being thrown over them on frosty nights or to protect them from hailstorms. The shifts made in some gardens to protect the plants causes much litter from

the protecting material left lying about. It is much better and almost as cheap to use glass lights, and these can be kept on through all the rough spring weather, and are useful to throw off superfluous rain-water as well as protection from severe frosts. Mats or canvas kept over the beds too much have a tendency to weaken the plants.

I have had Tulips planted where they were sheltered from east and north winds, and had not been removed for fifteen years; they were common varieties in clumps, and they never failed to flower freely. Of course, no one would recommend this culture for choice varieties. On the other hand, it is certainly quite unnecessary to make a border as if it were intended to grow prize Grapes. Splendid Tulips can be grown in ordinary garden soil merely by working the ground well to the depth of 18 inches, and it is very desirable that the soil should be exposed to the action of the atmosphere for two or three months before planting.

The best time to plant out Tulip bulbs is about the middle of November or a week or two earlier, time and weather permitting. Some decayed manure should be mixed with the soil at the time of trenching, and at the time of planting decayed fibrous loam should be placed on the surface of the beds to the depth of 4 inches. This will raise them above

the ground level. A good width for the beds is 4 feet, and if there are several beds the alleys between should be 18 inches wide. The outside rows are 3 inches from the edge of the beds, and five more rows are 7 inches asunder. There are seven rows in each bed, and the fanciers plant the bulbs so that the tallest-growing varieties are in the centre of the beds. They are termed first, second, third, and fourth-row flowers. In planting, too, the colours are mixed, a rose, a bybloemen, and bizarre being planted alternately. In planting make a hole to the depth of about 4 inches, place a little river-sand in the bottom of the hole, press in the bulb, and drop a little sand over it. Most of my experience in growing Tulips has been gained in the London district, but I remember discussing this matter some twenty years ago with the late Mr. Barlow of Stakehill House, and he said it was better not to plant out the bulbs until December. He stated that if the bulbs were planted late they started to push out their rootlets at once, and were not so likely to be injured by the cold, wet soil. The root-action in November is sluggish, and as regards the northern districts I would trust to the information one may be enabled to glean from their practical experience. It would be well if some means could be adopted to keep the ground dry by placing over it some material to throw off the rain-

water from the beds previous to planting. The Tulip plant near London will appear above ground early in January in some seasons, and at the latest by the end of that month. If the weather is mild growth is rapid, and the plants certainly should be protected. Glass is far superior to any other form of protection.

When two beds run parallel to each other I drive a row of posts into the ground on each side of the alley. These stand 4 feet 6 inches out of the ground. A rail is nailed on the top. Along the outer sides of the beds there must be another row of posts 3 feet 6 inches out of the ground, and a rail on top. On these rails rest garden frame-lights 6 feet long. This carries the water beyond the beds and keeps the plants dry. Some light tiffany or canvas is nailed to the posts to keep the wind from blowing on the plants or to break the effects of drifting rain or snow. When the Tulip bloom is developing it is easy to shade the glass from hot sunshine; also, in order to get good blooms, I mulch the beds with decayed manure, and it may also be necessary to give water. This should be applied between the rows over the manure, but care should be taken not to wet the foliage. The beauty of a Tulip bed is sadly marred if the foliage is injured.

JAMES DOUGLAS.

#### TULIPA KAUFMANNIANA.

THIS pretty Tulip has buds about 2 inches long, tapering to a point, and externally flamed rather decidedly with carmine or scarlet. The inner segments are white, with an occasional faint line of scarlet on the reverse side. This, however, is only seen as the flowers day by day reach their full size of bud, thus creating an interest from quite an early stage. Presently, when the flowers expand, we see a finely proportioned, creamy white, very substantial-looking blossom, and, with its huge blotch at the base of richest orange, possessing all the beauty of one of the newer Water Lilies, a notion conveyed by the substance of the petals. It is amenable to cultivation, not merely existing, but succeeding and improving with years. The best position is a warm border in sandy loam, or a warm spot in the rock garden. This handsome plant is from Turkestan. No species is more full of promise for the future, and none more worthy of an extended cultivation.

J.

#### THE LAWN.

(Continued from page 183.)

**A**FTER sowing the surface of the land should be well raked with an iron rake, and then rolled several times over with a heavy roller. If the lighter seeds are not well pressed into the soil they are in danger of being blown away by the wind. In laying down a lawn many are under the impression that any ordinary grass seed will answer the purpose. This is a great mistake. Special lawn grass mixtures are prepared by our best seedsmen, and these only should be sown. One pound of this seed to the pole of ground is the recognised quantity to sow. This may appear to many to be too large a quantity for so small an area, but if a good thick growth is desired quickly it is none too much. If the conditions of soil and weather are favourable to the growth of the young grass, it is possible to have the lawn in condition for light use by the end of the summer; but the owner will be well advised not to use it for playing on until the second season. As soon as the young grass

TULIPA KAUFMANNIANA. (Natural size.)

appears above ground a light roller should be drawn over it, and when about 4 inches high it should be cut with the scythe, and not too closely. It is better to cut it the second time also with the scythe; afterwards the lawn mower may be used, but care must be taken during the summer not to cut the young grass too short.

#### MOSS ON LAWNS

is often troublesome. Its presence generally indicates poverty of soil or the absence of proper drainage. Should the latter be the cause it is hopeless to look for improvement other than from effective drainage. If poor condition of the soil is the cause the remedy is easier and less expensive, and consists in raking (or harrowing if the lawn is extensive) as much of the moss from the turf as can be extracted in this way, and dressing the lawn afterwards with the following soil mixture: To one cartload of ordinary rich garden soil add  $\frac{1}{2}$  cwt. of bone-meal, the same of quick-lime, a barrowload of ashes from the burnt refuse heap (or potash in small quantity in some other form), with a light sprinkling of nitrate of soda crushed small, all to be well mixed together a fortnight or three weeks before being used, and applied at the rate of nine cartloads to the acre. Choose a dry day for the work. As soon as the soil has been spread and is moderately dry lawn grass seed at the rate of  $\frac{3}{4}$  lb. to the pole should be sown broadcast over the soil dressing, well raking it in, and afterwards roll with a heavy roller. I have never known this treatment to fail in bringing about a great improvement in mossy and poor lawns, and if annual dressings of this nature are continued for a few years the lawn will be ultimately entirely cleared of moss. From the middle of March to the middle of April is a good time to carry out this work.

#### WEEDS.

Noxious weeds are sure to find their way from time to time into the best and most carefully laid down lawn. Dandelions, Daisies, and Plantains are the most troublesome. The best way of clearing these weeds I have found is to employ boys or women to cut the roots deep down with a strong-bladed knife, and to pull up the Daisies by the roots. It may appear a tedious business, but it is wonderful how soon a large area of land can be cleared of weeds in this way. There is no other method so effective. Various other methods are recommended, such as applying salt or carbolic acid to the cut stem of the Plantain, Dandelion, or Thistle, which are among the most difficult of lawn weeds to eradicate. With regard to Daisies, which are so common and give so much trouble on lawns, it is claimed for a "lawn sand" which is advertised that it will destroy them without injuring the grass. The objection I have to these remedies is that with the application of the former there is danger of burning some of the grass surrounding the stems of these strong weeds, leaving behind a number of brown, ugly spots, which disfigure the lawn for the remainder of the season. In a less degree the same danger applies to the application of lawn sand for the destruction of Daisies, in so far that if a too strong dose is applied, either through accident or ignorance, damage to the grass for a time will ensue; but if applied with care, strictly according to the instructions given, and before the growth is too advanced, this sand will undoubtedly thin out the Daisies, and cause only a temporary and harmless discolouration of the grass.

#### WATERING.

If the weather is exceptionally dry in early summer provision should be made occasionally

THE SUGAR MAPLE WOODS IN SPRING (AMERICA).

to water the young grass, or there is a danger that some of the lighter seeds may not germinate freely. It sometimes happens that the seeds were not so evenly distributed at sowing time as they ought to have been. This will at once be apparent when the seeds begin to grow, and on any vacant or thinly-covered spaces sow more seeds, and cover them lightly with a sprinkling of soil well pressed down.

#### MOWING THE LAWN.

The growth of the young grass is often hampered and weakened by the use of a machine not in proper condition. If the knives are not properly adjusted to the plate the young grass is not cut off, but torn off, leaving the grass bruised, and not infrequently pulling the young plants up by the roots. It is most painful to see the harm frequently done to the lawn because of workers not understanding how to manage the machine, thus leaving the surface rough and untidy as compared with that cut by a machine in good condition and in the hands of a competent man.

OWEN THOMAS.

## TREES AND SHRUBS.

### SOME LITTLE-KNOWN ORNAMENTAL WILLOWS.

**I**N addition to the common red and yellow-barked Willows, which are so much appreciated for the beauty of their brightly coloured stems in winter, there are others equally interesting if not so highly ornamental, and the undermentioned species and varieties are worthy of inclusion in any collection of hardy trees and shrubs. To produce the best effects with these Willows it is, of course, necessary to mass them in quantity, but where a want of sufficient space or other reason prevents this, excellent results may be obtained from single specimens or small groups, especially when these are planted at the edges of streams, lakes, &c., and, as is well known, Willows revel in a heavy, wet soil. To retain the pleasing colour of the bark it is necessary that the shoots receive an annual pruning, and this should be done about the end of March or beginning of April, cutting the plants clean to the base, and thereby inducing them to form a sturdy growth. If it is desired to increase the stock cuttings between 9 inches and

1 foot in length can be made of the prunings, and they will root readily if firmly inserted in a shady border.

*Salix daphnoides* (the Violet Willow).—The twigs or branches of this Willow are a very pleasing and distinct colour, being pale red overlaid with a glaucous bloom. The foliage is also glaucous, and if the stems are pruned annually, as advised above, this forms a neat shrub about 4 feet in height.

*S. grandiflora moschata*.—A striking variety when used in quantity, the bark being a very deep purple or almost black.

*S. babylonica annularis*.—A most interesting shrub, the foliage being peculiarly turned back so that each leaf forms a ring. This is a small-growing variety, and though of no value for winter colouring, it merits extended cultivation.

*S. purpurea* has reddish purple stems, which are very noticeable when massed.

*S. laurina* is a strong-growing Willow, with black stems reaching a height of fully 7 feet in a season.

*S. incana* (the Rosemary-leaved Willow, sometimes called *rosmarinifolia*).—This is undoubtedly one of the best Willows we have, and if only partially pruned soon forms a spreading, large bush. The leaves are green above and silvery on the under side, and when gently stirred by the wind in summer have a most pleasing effect. Though the bark is not very conspicuous, excellent results are obtained from the foliage by planting in groups on the water's edge, especially by large lakes. There are, no doubt, other equally interesting Willows, but the above are a few that can be recommended to planters of ornamental shrubs.

*Elstree*.

A. E. THATCHER.

### THE SUGAR MAPLE.

**I**N America we are proud of our aboriginal forests; we are proud of the large size of the trees and of their fine proportions; we are proud also of the numerous species, their wide range, and their thrifty growth. Yet Americans in general are not so proud of these things as they ought to be, I think. At least it seems to me they are often inordinately vain of much less notable matters. Amongst our noble species of native trees perhaps none ranks higher than the Sugar Maple. Through the North-Eastern States and Eastern Canada this is the most important and characteristic species. In many places it appears in large areas as almost pure woods, and in many places these Maple woods are preserved and encouraged for the annual yield of Maple sap. The sap is boiled down and made into syrup or sugar. The sugar has the advantage of shipping better to market, and plays a large

part therefore in commercial enterprises. The desirable product, however, is the syrup, which is much prized by all who know it in its purity. For many years the demand has greatly exceeded the supply, and it seems probable that such will be the case for many years to come. The illustration shows a "sugar bush" or "sugar orchard" in the spring, at the latter end of the sap-gathering season. The snow has just disappeared, the sap has nearly ceased to run, and the sap buckets will soon be put away for the summer.

## AN HOUR WITH THE HOLLYHOCK.

### PROPAGATION.

WE now proceed to offer a few remarks on propagation. We know of but four modes of propagating the Hollyhock: (1) By seed; (2) by cuttings; (3) by dividing the roots; and (4) by grafting. The first mode has been already discussed; it remains for us to consider the others. Propagation by cuttings is the best mode of obtaining good plants, and the practice may be carried on from March to October. Most of the old plants give an abundance of young shoots early in spring, and so soon as these become a little hard they may be cut off close to the stem, leaving about three of the best shoots for slower spikes. Place three or four cuttings around a 5-inch pot in a rather light sandy soil; plunge them in a close frame, where in a few weeks they will have formed new leaves and roots and may be potted off, each in a separate 4-inch pot. As fresh shoots form on the old plants they may be treated similarly up to midsummer, after which period we would prefer leaving the wood to become quite hard before making the cuttings. In the latter case a single eye is sufficient to make a plant; but the wood-shoots and not the flower-shoots should be chosen. It sometimes happens that the eyes developed at the base of a main spike produce wood-shoots, but they more usually produce flower-shoots; the latter take root and form plants, but are not of the best description. Cuttings made from the single eyes may be cut obliquely at the lower end and completely buried beneath the soil, leaving the foot-stalk only protruding above; they should then be placed in a closed frame and the eyes quickly push through the soil and form stout, healthy plants. These when rooted may also be transferred to single pots, there to await transplantation in autumn or spring, as before recommended.

Propagation by division is best carried out in autumn, immediately that the flowering is over. A large, well-ordered plant may sometimes be divided into several, but in general three or four is a more advantageous number. Nothing certainly is gained by breaking the old plants into too many pieces; every separate part should carry with it a good share of roots. Seedlings and others that may bloom late cannot be divided till the spring. March is perhaps the best time, and the fragments, if not broken too fine, will flower well during the first autumn.

Propagation by grafting may be performed to the greatest advantage in spring. Dig up any old plants not valued for blooming, and cut off the fleshy roots about the thickness of the little finger into 1 inch or 2 inch lengths. On these graft the young shoots, inserting the place of junction beneath the soil, giving to each a separate pot, and placing them in a

close cold frame. This mode of propagation we describe, but do not recommend. Plants raised from cuttings or seed are certainly preferable.

It is but the few who grow for exhibition, but they are often the most ardent cultivators, and we must say a few words on this subject ere we conclude.

There are two modes of exhibiting Hollyhocks, by single flowers and spikes. Some cultivators have advocated the withdrawal of prizes for single flowers, and depending on spikes alone. It is freely admitted that the exhibition of spikes creates a great display, and affords a truer idea of the nature and properties of the flower. On this ground, then, we admit the desirableness of encouraging this mode of exhibiting, but doubt whether the entire exclusion of single flowers will not prevent many amateurs from entering the list as competitors. To exhibit single flowers does little damage to the garden at home, and they are easily conveyed to the place of exhibition. To exhibit spikes requires too great a sacrifice where a few plants only are grown; and, moreover, they form, however, closely stowed away, a somewhat cumbersome package. We know that many amateurs derive as much pleasure from the gratification they afford others by their pursuit, as in marking the brilliancy of colour and symmetry of form, or inhaling the sweets of their favourite flowers. The most emulous of such would pause ere he cut seven spikes of his finest kinds from a limited collection. He could not reconcile himself to behold tarnished in a day what would have given pleasure for a lengthened period had the spikes been allowed to remain on the plants. We think, then, there should be two classes, one for spikes and one for single flowers. Make the former the more valuable prize, as it deserves to be, but do not exclude the latter.

The spikes exhibited usually vary in height from 2 feet to 4 feet. The flowers near the base of the stem are generally the finest (although this depends in some measure on the state of the weather in which they are formed and expanded), and consequently the aim should be to preserve such. To this end all lateral flower-spikes should be destroyed, and the top cut off the main about 4 feet from the lowest bud, at the time this expands that the flowers may close over the top, and the spike look complete. This, which is called "crowning" the spikes, is most essential when cultivating for exhibition. It is an operation of some nicety; not that it is difficult to crown the spikes but difficult so to manage them that they are in perfection on a given day. Practice is the best guide; indeed, the end can only be obtained with certainty by the best considered practice.

By shading, the greater part of the spike may be kept in a showable condition for ten days or a fortnight. In choosing for exhibition, whether spikes or single flowers, we should be guided by the standard previously laid down; the nearer the flowers approach to that the more perfect should we consider our stand. It may not be necessary for the mere cultivator for amusement to dive so deep into the science of floriculture; this, of course, is a matter of choice, but the exhibitor should certainly obtain a clear conception of what constitutes a good flower before he enters the field of competition.

The Hollyhock had, perhaps, scarcely been exhibited in its grandest state until recently, owing to the Dahlia shows at which it had usually figured falling behind the period of its greatest beauty. To those, however, who witnessed the exhibition at the Surrey

Zoological Gardens, on the 22nd of August last year, nothing need be said in its praise as a stage flower. The beautiful columns of brilliant and well-contrasted colours, relieved by the quite protrusion of numberless small green leaves, formed a picture which a Baptiste or a Lance might have rejoiced to look upon and longed to copy. And while listening to the opinions of various amateur and professional cultivators as to the result of this first attempt at a Hollyhock show, one pronouncing this flower to equal the Tulip in brilliancy and beauty, another extolling the richness, variety, and quantity of colour presented to the eye, all agreed that the attempt was decidedly successful, and that the Hollyhock would henceforth rank as a first-class exhibition plant.

W. PAUL, F.L.S.

(To be continued.)

## THE FLOWER GARDEN.

### A BED OF SALPIGLOSSIS.

SALPIGLOSSIS SINUATA, otherwise known as *S. variabilis*, from the variable colour of the flowers, is a member of the Solanum family, closely allied to the *Petunia*, and has similarly hairy and somewhat sticky stems. It will not grow quite of itself like Sunflowers and Geraniums, while the beautiful colours, some of them quite impossible to describe at all accurately, unless we include them under the modern term "art shades," are such as do not appeal to those whose taste in the colour of flowers has not been educated. Their large pencilled, funnel-shaped flowers are sometimes compared, not inaptly, to *Alströmérias*. The ordinary varieties of *Salpiglossis* grow about 2 feet high; but there is a dwarf bedding sort which grows from 1 foot to 1½ feet only, though it is not to be preferred even for bedding purposes. There is a distinct variety called *S. variabilis superbissima*, which forms only one leading stem, and that a stout one, 2 feet high and nearly as large at the base as one's finger, with the flowers thickly clustered round it, especially on the upper part. They are of varied colours, but all veined with gold. The older *S. variabilis* is of a much more branching habit and more slender. There are several named sorts of very beautiful colours, most of them veined with gold. The flowers have a rather long throat, and are funnel-shaped, as stated above, while in the flowers of the variety *superbissima* the throat is wide open and short. If this latter variety is grown, its stout unbranched central stems render them unsuitable for pegging down, as *Petunias* are often treated, while their compact growth necessitates planting them more closely together. Whereas 7 inches or 8 inches would be about the best distance for this variety, 9 inches or 10 inches, or even 1 foot, would be a better distance for the *S. variabilis* if grown upright, while 1½ feet would not be too much if they are going to be pegged down. In the latter case the bed can, with a little management, be nicely covered all over, especially if a few reserve plants are kept in pots for putting in any thin places. But with plants 2 feet high, if they are planted close enough together to hide the soil, many of the side shoots and lower blossoms will not have the opportunity to show to advantage. Hence, if grown upright, it is a good plan to arrange the bed after the manner of a bed of *Fuchsias* or other tall plants, 1½ feet to 2 feet apart, and cover the ground between with some dwarf or creeping plants. *Sanvitalia procumbens* is a creeping plant, with yellow Daisy-like flowers the size of a shilling and crimson-brown centres. It blooms profusely all the summer, and forms a good setting for the *Salpiglossis*, harmonising well with them, as so many of the varieties are golden veined, and sometimes entirely golden. It need hardly be added that sticks must be put to them if it is desired that the upright position should be maintained.

Whether the older or newer sort is grown, it is of much more interest to get a packet of mixed seed, as we never know then what we are going to get. If obtained from a nurseryman with a specially good strain, some very fine varieties will be obtained. It is a half-hardy annual, and should be sown in gentle heat in March, or in a cold frame in April. The seedlings should be pricked out when large enough to handle into some good sandy soil in pans or boxes, and kept under glass till the end of May, when they should be gradually hardened off, always remembering that plants, even out of a so-called cold frame—which often gets extremely hot in May—suffer very much if put straight out into the sunshine in the open. They should always be set in complete shade for a day or two, and if a wet or damp day comes conveniently for the purpose all the better.

The *Salpiglossis* is particular as to soil and situation. One year I had a bed of them in a shady position, and the soil was a wet one and of close texture. The plants seemed to grow very well for a time, but first one plant and then another withered away, and even those that survived long enough to bloom were not safe, for one after another suddenly became limp and

*Salpiglossis* this is especially necessary, as we can never be sure one or two will not die, even in the most favourable positions. ALGER PETTS.

## CARNATIONS IN THE TOWN GARDEN.

(Continued from page 180.)

CONSIDER March to be the best month for planting Carnations in the town garden. If the soil has been dug and manured in the autumn, and dug again in the spring, it will be in good condition by March. Choose dry weather for planting, for there is no danger of the soil being too dry so early in the year. It is a bad plan to plant when the soil is wet, for it is then impossible to work the latter well among the roots, and this is essential. Put the plants in the ground so deeply that they will not sway about from the base or "collar," as it is called. If they are planted too shallow they never take firm hold of the ground, and consequently do not grow as well as they

An exceptionally wet winter might cause the loss of nearly all the old plants, or at least so cripple them as to render them next to useless. In most town gardens there is not sufficient room to devote a whole border to Carnations, but where this can be done I should certainly advise it. Sussoping the borders to be devoted chiefly to herbaceous perennials, the Carnations should be planted in small clumps or groups at intervals; they ought not to be planted singly, dotted about, or in lines. Six plants make a pretty little clump, and if several clumps are arranged in an irregular fashion along the border they will be seen at their best. Restrict each clump to one variety; do not mix the colours indiscriminately—make one clump of a red variety, another of a white, and so on. If this is done the effect is much more pleasing than if differently-coloured varieties are planted in the same clump: then each loses its individuality and makes an inharmonious whole.

### SUMMER TREATMENT.

The first matter to be attended to will be the important one of weeding. Where everything is favourable to plant growth, *e.g.*, in well-tilled country gardens, Carnations often grow well

whether the weeds are destroyed or not, but in the town garden things are different; the plants must be under no disadvantages from which it is possible to free them easily, and among these may be included weeds. It is an easy matter to pull them up, especially if a day is chosen when the soil is moist; they come up much more easily then. The great thing is to begin weeding early, before the weeds come into flower; once they have flowered and seeds have ripened and fallen, the weeds have gained an advantage, and in a week or two dozens of tiny green plants will appear where only one or two grew before. Weeds rob the soil of nourishment, therefore they must be rigorously destroyed, and especially in the town garden, where the supply of plant food is so limited. Another point worth mentioning is the good that is done by keeping the surface of the ground loose; this is especially beneficial in dry weather, for it prevents the escape of moisture, and so directly benefits the plants. Perhaps most important of all is a mulch of manure when the buds are showing; it should be placed in and around the clumps of plants. It keeps the roots moist, stimulates growth, and improves the flowers. Staking will need attention also, but this is quite a simple operation now, since the introduction of improved stakes. These are made of twisted wire, and the Carnation stems should be intertwined; tying is hardly necessary. These stakes should be painted sage green, and should not project beyond the top of the plant, neither should they be too short to support it properly. They are of neat appearance, and a great improvement upon the old wooden stakes and raffia.

Watering is, of course, very important, and all who value their plants will attend to them carefully in this respect. If the summer is dry the borders in a town garden generally dry quickly; so care must be taken that the plants do not suffer from want of water. Evening is a good time to water them, for then the border becomes thoroughly moistened. If the watering is done during the day some of the moisture evaporates, instead of reaching and benefiting the roots. Never let the border become dry or the plants will certainly suffer; they will become stunted, and the flowers will be disappointing. The carrying out of these cultural details means much more to Carnations in an urban garden than to those in the country, for they must be aided and encouraged in every possible way.

### VARIETIES.

It would be useless to give a long list of varieties of Carnations for the town garden; the best

NEW WHITE CARNATION THE "BRIDE" IN SHALLOW BENCHES IN A NEW JERSEY NURSERY.

gradually dried up, until by the end of August not a dozen plants remained alive on the bed. A friend of mine had an experience with them almost as bad in a somewhat similar soil, though in a sunnier situation. The first necessity for their successful culture is a sunny position, and the second is a light, rich, sandy loam. Though they need a good soil, yet it must not be full of fresh manure, as that seems especially fatal to them. If some thoroughly rotted manure is not handy, some old Marrow or Cucumber bed should be well mixed with the soil, and if this is not to be obtained, it is better not to manure the bed at all. The bed should be well in bloom by the end of June, and in its full beauty before the end of July, and it will last throughout July and August, and in a favourable season through most of September. They are admirably adapted for cutting, but if wanted for this purpose it would be better to have a bed of them in the reserve, or cut flower, garden. It is well with all summer beds to have one or two plants of the same thing grown in pots to make good any casualties on the bed, and with

otherwise would; if the base is deeply buried the roots will be too far beneath the surface, and air will not reach them. It is not necessary to cover any of the leaves; if the basal ones are partially covered the plant will be deep enough. Make the soil fairly firm about the roots, either with the hand or with the handle of the trowel used in planting. Carnations root better in soil that is made comparatively firm. They do not require a very rich soil; in this they make a vigorous but soft growth, and are of little use the next year. If, however, the growth of the plants is harder, they may be kept for another season's flowering. In advising the admixture of manure, I had in mind the kind of border usually found in a town garden, and which certainly benefits by dressings of manure. I might mention here that one should never rely altogether upon plants that have bloomed once for the following season's display, as during the winter some of them are almost sure to die off. They do not do so to the same extent as young plants, but it is always advisable to propagate every year to prevent disappointing results.

plan is for the owner to try a number of different ones, and he will soon find out by experience which are the most suitable for the conditions of soil and surroundings that prevail in his garden. The following varieties have been selected because of their hardy constitution and free-flowering habit; they are all self-coloured. The reader can obtain a list of good fancy varieties from any Carnation grower if he wishes to grow these, and there is no reason why some of them, at any rate, should not be grown successfully in the town garden. It would be well, however, to begin with those mentioned.

*White*.—George Macquay, Gloire de Nancy, and White Star.

*Red*.—The Old Clove, Paul Engleheart (a dwarf variety of it), and Uriah Pike.

*Scarlet*.—Dundee Scarlet and Quentin Durward.

*Salmon-pink*.—Raby Castle.

*Dark rose*.—Francis Wellesley.

*Yellow*.—Miss Audrey Campbell.

#### PROPAGATION.

It is not necessary here to give full details as to the propagation of Carnations, for that has been dealt with on other occasions. The shoots should be layered early, say, in late July or early August. The earlier they are rooted the better plants will they make. In the month of October it is usual to remove the rooted layers from the old plants, and to transplant them to their permanent quarters, *i.e.*, in the border where they are to flower. But here again the method of procedure must be modified in the case of Carnations in the town garden. Instead of transplanting the layers to another border prepared for them, they must be potted up into small pots in a soil containing a fair amount of leaf-soil and placed in a garden frame, there to remain during the winter; in fact, until March, when they may be planted out. Instead of being put in small pots, the rooted layers may be planted in the frame in which a bed of light soil some 9 inches deep has been prepared. There the plantlets remain until planting out time in March. Personally, I much prefer potting up the runners, for the condition of the soil during winter can then be regulated more satisfactorily than when they are planted out. Once the bed of soil gets wet—as it is likely to do in the middle of winter—it is impossible to get it dry again before the weather improves, and meanwhile some of the plants might die. It is astonishing how little water Carnations in pots need during winter. I have had them in a cold frame throughout the winter months, and have given them no water at all for weeks, yet the soil still remained moist. There would seem to be no doubt about the wisdom of wintering the rooted layers in a cold frame so far as Carnation culture in the town garden is concerned. They are then safe from damp, which, together with the danger of their freezing while water is still in the axils of the leaves, is the chief difficulty in keeping them until the spring. A cold frame is very cheap, yet it is indispensable to those who wish to propagate their own Carnations instead of annually buying them. It is a pity that so many do the latter when layering is so simple. The initial cost of the frame is saved over and over again by not having to purchase plants.

Last year I tried another method of keeping the layers through the winter, but we had such an exceptionally wet season that the plan can hardly be said to have had a fair trial. Instead of removing the layers from the parent plants in October I left them alone, thinking that with the assistance they derived from the old plants they would be able

better to withstand the winter's cold and wet. A good many of them, however, lost their centres—their "hearts," as gardeners say—and are practically worthless, while the remainder look far from happy. When I contrast these with those that have wintered snugly in the cold frame, I can have no hesitation in saying that the latter is a *sine quâ non* to the successful culture of Carnation layers during the winter months.

#### PROPAGATION BY SEED.

Raising Carnations from seed is a method that appeals to many, and particularly to the town gardener. There is always a delightful uncertainty about the results to be obtained from a packet of seeds, and, providing one obtains seeds from a reliable source, a good percentage of double

generally practised is as already stated—*i.e.*, sow the seed in April and grow on the seedlings during summer, finally planting them out in September. If, however, the seed is sown in January in a warm house, and the seedlings are encouraged to grow fairly quickly in an intermediate temperature (not higher than 60°, or the tiny plants will be weakened), so as to make good plants for placing out of doors in May, then they will bloom the same year a little later than those propagated the previous year. This plan of flowering the plants the same year, treating them as annuals, has much to recommend it to the town gardener, for it does away with the necessity of keeping the plants through the winter. There is certainly more interest attached to the raising of Carnations from seed than from layers. One always knows what to expect from the latter, while seedlings are a continual source of interest and expectation, for one never knows what they will produce. It is important to buy good seed, however, otherwise the results will probably be disappointing. The only thing that may prevent the town gardener from adopting the plan of culture above described is the want of a heated greenhouse or frame. Without either it is impossible to get the seedlings along quickly enough. Still, most urban gardeners possess a small greenhouse, and I am sure a small portion of it could not be turned to better use than by raising seedling Carnations; in late summer and autumn they will be invaluable for cutting. In a garden within a very few miles of Charing Cross hundreds of plants are grown in this way, and the gardener is able to gather hundreds of blooms for house decoration. One of our best Carnation growers states that plants flowering from seed sown in March of the previous year will produce from 100 to 150 blooms each; one could hardly expect to gather so many from plants flowering the first year from seed; but they, too, give a very satisfactory harvest. Among seedlings there is always a certain percentage of single flowers; but supposing the Carnations to be required for home decoration only, the singles do as well as the doubles; in fact, when arranged with them, they improve rather than detract from the display. T. H. H.

(To be continued.)

#### NEW WHITE CARNATION —THE BRIDE.

I SEND you two photographs of a new white Carnation, showing results under glass in America. Mr. J. N. May of Summit, New Jersey, is the distributor of this variety. It has received a number of awards from the principal horticultural societies in the States. It is very free-blooming, and the white is quite pure. The individual flower is 3 inches to 3½ inches in diameter, and the stem 14 inches to 16 inches long. It has a vigorous habit, as will be noticed by the plants growing in the shallow benches. D.

#### AMARYLLIS BELLADONNA IN GUERNSEY.

WE are indebted to Mr. H. C. Smith, Caledonia Nursery, Guernsey, for the photograph reproduced in the accompanying illustration. Mr. Smith writes that "it represents part of a bed of *Amaryllis Belladonna purpurascens maxima* in the Caledonia Nursery last autumn. The bed measured 36 feet by 18 feet, and when the

FLOWERS OF THE BRIDE CARNATION. (Much reduced.)

flowers in a great variety of colours will be had. Seed should be sown in April in a greenhouse or cold frame, and preferably on a hot-bed. Carefully attend to the seedlings as they progress by repotting, watering, and gradually inuring them to the open air. By the month of September the plants will be ready either for planting in the border where they are to remain till flowering time, or they may be kept in pots throughout the winter and planted in their permanent quarters in March. If they have made good growth and are vigorous, and the garden soil is not exceptionally heavy and likely to become soddened, the plants may be put at once in the border; but if they are rather weakly and the soil is not congenial, keep them in the cold frame until March. Although it is not usual to grow border Carnations so that they flower the same year in which seed is sown, they can be made to do so by sowing early. The method

photograph was taken there were over 1,000 spikes in bloom and bud. This form is quite the best we have ever grown, and will give satisfactory results where the ordinary forms of the Belladonna Lily are a failure."

**NOTES ON HARDY PLANTS.**

**COLCHICUM HYDROPHILUM.**

**A** BEAUTIFUL little plant belonging to the spring-flowering section of the genus, in which the flowers and leaves appear at the same time. The latter, however, are not fully developed for some time after the flowers are over and eventually attain a length of 6 inches and a width of over 1 inch. The corms are about the size of a small Walnut, chestnut brown in colour, and produce from three to five flowers each. These are 3 inches to 4 inches high, longer than the leaves at the time of flowering, and of a bright rose colour. Corms of this plant were received from Asia Minor in 1898, and flowered in February, 1899. It is found on the Taurus Mountains on both the north and south sides, but not at a lower elevation than 3,250 feet above sea level, extending upwards to a height of 6,500 feet. It grows in places where it receives an abundance of water, produced by the melting snow, during the flowering and growing period. From July to October the same position is dry, and during this period the corms are thoroughly ripened off. A very useful plant for the alpine house and of easy culture in sandy loam, it is quite hardy in the border, but is more suitable for the former purpose, or for a corner in the rock garden.

W. IRVING.

**ERANTHIS CILICICUS.**

THIS is a much finer form than the old common Winter Aconite (*Erantthis hyemalis*), with larger

COLCHICUM HYDROPHILUM IN THE ALPINE HOUSE AT KEW.

finely cut leafage, purplish stem, and larger yellow flowers. This species generally flowers a little later than the common Winter Aconite.

**DIVERSITY IN SEEDLINGS OF CAMPANULA BARALLIERII.**

THOUGH this *Campanula* is supposed by some to be a synonym of *C. fragilis*, it is yet so distinct in foliage and in the colour of its flowers as to justify the bestowal of a distinctive name, and there is a remarkable diversity of character in some of its progeny obtained from seeds. Some favour the parent, some revert to *fragilis*, some partake of the downy character of growth of *Mayii*, some are much more characteristically pubescent, while a very few have the variegated character. The variety in the seedlings is delightful, and I am anticipating the blooming time with considerable interest. The one drawback is that there are so many seedlings that they are grown in my cold house to the discomfort of other things. I think that if anyone will undertake during the coming summer to cross-fertilise *C. Mayii* and *C. Barallierii* that a very interesting progeny might result. They are quite hardy plants, and, being

evergreen, have an interest during winter, and they are quite at home in a cold house. At the same time they well repay a generous treatment.

R. DEAN.

**IRIS UNGUICULARIS.**

(*IRIS STYLOSA*.)

AN evergreen Iris, with long linear leaves and showy flowers. If planted in a sunny spot against a south, east, or west wall and in well-drained soil it will produce large showy flowers from December till April. There are several forms, all of which are well worth growing. The type has rather long, broad foliage, and large, pale blue flowers, the falls slightly marked white. *I. unguicularis lilacinum* has paler flowers and white netted falls. *I. unguicularis speciosa* has shorter and more narrow foliage, with later deep blue flowers. *I. unguicularis angustifolia* has narrow, deep green foliage and pale blue flowers, and closely allied to this is *Iris cretensis*, with grassy-like, glaucous foliage, and large showy flowers only just now commencing to show. In colour they are similar to the form *speciosa*. *I. unguicularis alba* is a form, or rather there are two forms, the one with creamy white flowers, the other with just a tinge of lilac.

**GALANTHUS NIVALIS VAR. SCHARLOKI.**

THIS form of our common Snowdrop is at present in full flower, and is noticeable among others mainly by its divided spathes, although on closer observation a further distinction is observable in the greenish markings near the apices of the small flowers. It is one of the most singular of Snowdrops in respect to its large, leafy, and divided spathe, which often recurves, and then looks like a pair of horns raised above the flowers. Anyone can recognise it among other Snowdrops, and its interest is not lessened by the knowledge that it is a natural form and not one raised in a garden. Its history is well known. It was found in some copses in the valley of the Nahe, in Western Prussia, a tributary of the Rhine, by Herr Julius Scharlok, a careful botanist, and named in his honour in 1868 by Professor Caspary of Königsberg. It has mainly been distributed by Mr. James Allen,

THE BELLADONNA LILY (*AMARYLLIS BELLADONNA* VARIETY) IN JERSEY.

I believe, but it is not as yet plentiful even among the few connoisseurs of the Snowdrop. From the first appearance of the flower above the soil this is an interesting *Galanthus*. On account of the division of the leafy spathe the flowers are not protected on piercing through the soil in the same way as those of most other Snowdrops, and the blossom appears like a small white ball. It gradually develops until the green markings on the outside and the divided spathes become more apparent. It does not strike one as a well-formed *Galanthus* in its shape, but it is undoubtedly interesting as one of the few abnormalities among the plants of a favourite genus. I have a nice clump of it now, and one can find about it something to study in the Snowdrop season. Mr. James Allen has raised several seedlings from *G. n. Scharloki*, but none of these is so pretty as the original. They are remarkable, however, for the variation from the parent they show. Some have the divided spathe, and some the green markings on the exterior, but a few are malformed. They do not succeed with me so well as the typical *Scharloki*. S. ARNOTT.

## USES OF BRITISH PLANTS.

### SOLANACEÆ.

**H**ENBANE (*Hyoscyamus niger*).—This, with opium, &c., formed a drug called "Dwale" in the Middle Ages to induce sleep for operations. The seeds were heated on a hot tile and the vapour inhaled in order "to slay the worms in the teeth." The plant is in the pharmacopœia, being valuable for its narcotic properties. It is a plant with a heavy disagreeable odour, clammy to the touch, from its glandular hairs. It bears dull yellow and dark veined, bell-shaped corollas. The capsule bursts by a lid falling off. The roots have been eaten instead of Parsnips with serious results.

Bittersweet, or Woody Nightshade (*Solanum Dulcamara*).—This common shrub scrambling over hedges is well known by its clusters of purple flowers and scarlet berries. The name "Bittersweet" is given from the taste of the bark, which is bitter, but followed by a sweet flavour. The shoots dried are used in British medicine for certain cutaneous complaints. The berries have proved poisonous to a certain degree to children. It was called "Woody Nightshade" by the old herbalists to distinguish it from the "Deadly Nightshade."

Garden Nightshade (*Solanum nigrum*).—This is a small herb with white flowers and purple berries. Like the last it has been used for the same purpose. The berries are more or less injurious, especially to children, but are often eaten by adults with impunity, especially when quite ripe, as the poisonous principle is chiefly associated with all green parts.

Dwale, or Belladonna (*Atropa Belladonna*).—A shrub some 3 feet in height, bearing dingy purple, bell-like flowers and smooth black berries when ripe. These are intensely sweet, and have proved to be fatal to children and others who have eaten them. The dried leaves form the drug of our pharmacopœia. They are strongly narcotic. It is an anodyne, and used for allaying neuralgia. The name Belladonna has its origin in the use as a cosmetic by Italian ladies, or perhaps for enlarging the pupil of the eye, a property possessed by the juice.

The Mandrake, a foreign species of *Atropa* (*A. Mandragora*), was used in Pliny's day as an anæsthetic for operations. The sleeping potion of Juliet was a preparation from this plant, perhaps the same as the Mandrake wine of the Ancients.

### SCROPHULARINEÆ.

Mullein (*Verbascum Thapsus*).—This plant has a tall stem, with very woolly leaves, and a dense spike of yellow flowers. The leaves boiled in milk have been strongly recommended as an emollient for coughs. It was formerly called Candela, because it was a plant "whereof is made a manner of Lynke, if it be tallowed," as it is said in the "Great Herbal." The down upon the leaves consists of stellate hairs, which form a sort of felt and

makes a good tinder when dry. It was called Hag-taper, being supposed to be the witches' broom upon which they rode through the air, but the true derivation appears to be from *haga*, a "hedge," and not *packe*, a "witch," with *taper*, a "candle."

Foxglove (*Digitalis purpurea*).—This is dangerously poisonous, having a strong action upon the heart. It is used medicinally for that purpose, but ignorant people have been poisoned by making a tea of the leaves.

Figwort (*Scrophularia nodosa* and *S. aquatica*).—These plants were formerly used as a remedy for scrofula, hence is derived the name of the family. They are—as so many of this order—emetic and purgative. It should be regarded with suspicion.

Cow-wheat (*Melampyrum pratense*).—This is said to afford good fodder for cattle. According to Linnæus the butter of cows fed upon it is remarkably rich and of a deep yellow colour. The term "Wheat" is said to have been given to it because of its sudden appearance among Corn on land being cleared from a coppice where it had grown. Cows and sheep are very fond of it. The Latin name signifies "black wheat."

Ivy-leaved Toad-flax (*Linaria cymbalaria*).—This now common plant was introduced from the Continent. It is eaten as a salad, having a hot taste, like that of Cress, hence it has been thought to have anti-scorbutic properties.

Speedwell (*Veronica officinalis*) was formerly used as a tea, an old Danish botanist, Simon Paulli, contending that it was the true Tea of China!

### LENTIBULARINEÆ.

Butter-wort (*Pinquicula vulgaris*).—This plant is common in wet places, especially in the West of England. Its leaves form a rosette, are spoon-shaped, and covered with glands, which catch insects and consume the nitrogenous substances from them. The Latin name, Gerarde says, refers to the "fatnes or fulnes of the leafe." The juice, he adds, was rubbed on cracked udders of cows, as it is done in Sweden. Linnæus states that in northern regions the fresh leaves are put into the reindeer's milk and strained. After a day or two it acquires a consistence and tenacity; the whey and the cream do not separate. It thus forms a favourite food in the north of Sweden. It does not act in the same manner as cow's milk.

### VERBENACEÆ.

Vervain (*Verbena officinalis*).—This plant was considered to have many virtues of old, but it has now fallen into disuse, as having none. It was called Hierobotana, or the "sacred plant." Pliny tells us that the messenger sent to an enemy to demand the restoration of property was called *verbenarius*, for he carried a spray of Vervain, which rendered him inviolable. It was also used for cleansing the table of Jupiter on the occasion of the feasts of that god. Houses were purified with it. As a drug it was much valued in the fourteenth century, as, e.g., the powder for stanching blood and healing wounds. The following is a curious test: "If a man lie sick, to know whether he shall live or die. Take Vervain in thy right hand, and take his right hand in thine; and let the herb be between, so that he does not know it. Ask him how he fareth and how he hopeth of himself. If he say he shall live and fare well, for certain then he shall live and fare well. But if he say he hopeth of no life, know well for certain that he shall die of that evil."

### LABIATÆ.

No member of this easily recognised family is poisonous, but the majority are characterised by strong scents, due to the presence of essential oils located in glandular hairs upon the foliage, &c. This imparts the odours peculiar to different species, as Peppermint, Thyme, Sage, Lavender, Patchouli, &c.

Spear-mint (*Mentha viridis*).—This is the cultivated garden Mint, and only known as an escape, but is believed to be derived from the wild Horse Mint (*M. sylvestris*), only indigenous in the South of England. It was much cultivated by the Romans and other Mediterranean nations.

Peppermint (*M. Piperita*).—This is also regarded as a cultivated form of Water-mint (*M. aquatica*),

which smells strongly of Peppermint. The drug "Menthol" is derived from a Japanese species (*M. piperascens*).

Pennyroyal (*M. Pulegium*).—This species was formerly highly valued as a medicinal drug as well as for culinary preparations, hence it was called "Pudding Grass." It was known as Piliolerial in the fourteenth century, and employed for various purposes, as to sharpen the eyes. It entered into the composition of "save" for wounds.

Thyme (*Thymus Serpyllum*).—This familiar wild flower is especially abundant on dry, heathy soils. The essential oil is strongly aromatic, so that it has long been cultivated, especially a variety known as Lemon Thyme.

Marjoram (*Origanum vulgare*).—This plant is particularly abundant on calcareous soils, as in the south-east of England. Like others the oil is an aromatic stimulant, and used as a remedy for toothache.

Ground Ivy, or Ale-hoof (*Nepeta Glechoma*).—This early-flowering creeping plant is bitter and aromatic. It has been used for flavouring ale. Hence it acquired the name of "Gill" from the French *giller*, "to ferment" beer; but as "Gill" also meant a "girl," the plant came to be called "Hedgemaidens." The juice of this plant with that of Groundsell and Plantain was supposed to cure small ulcers in the eye, and to remove the white specks which sometimes appear in horses' eyes.

Horehound (*Marrubium vulgare*).—This has long been valued as a remedy for coughs and pectoral complaints. A tea is made from the woolly leaves.

Wood Sage (*Teucrium Scorodonia*).—This is a common plant in heathy districts. It has strong tonic as well as the usual aromatic properties of labiates. It was formerly used as a substitute for hops under the name of "Ambrosie" in Jersey.

Betony (*Betonica officinalis*).—It is remarkable that this plant, which has no special virtues, was long regarded as a panacea for all the ills that flesh is heir to. Moreover, recipes and many pages descriptive of the virtues of Betony are given in the fourteenth century medical books, including its use for driving away devils and despair!

G. HENSLAW.

## ALDERSEY HALL.

**A**LDERSEY HALL, the residence of Hugh Aldersey, Esq., J.P., stands in a well-wooded park, nine miles south of Chester, looking towards the Broxton Hills. Two sides of the hall are bounded by the park and on leaving the house by the western exit one comes to a small lawn, from which a path winding beneath old Yew trees leads to the beautiful and secluded gardens. This side of the hall is entirely covered by a single plant of Ivy (with a trunk 4 feet in circumference), through which the cable-like stems—some 9 inches to 15 inches in girth—of a Clematis *Vitalba* run up to the roof. The gardens and pleasure grounds are twelve acres in extent, and have existed in their present form since the early part of last century, though some alterations and improvements have been made from time to time, principally during the last few years. The garden proper is laid out more or less in a natural style, giving different aspects, the flowers and trees being grouped in picturesque ways. Here one is reminded of the well-known lines:

"He gains all points who pleasingly confounds,  
Surprises, varies, and conceals the bounds."

Fine effects are obtained by combining various forms which aid each other and give a succession of pictures. There is no set pattern to weary the eye, but quiet grace and verdure and feasts of colour through several months of the year. Groups of beds of sufficient size to allow of bold massing are quite a feature in Aldersey Hall gardens. It is impossible to say when the gardens were first laid out, but as the family has resided at Aldersey for many

generations it is probable that it dates from early times. That it existed more than 200 years ago appears certain from some entries in "An Almanack for the Year of Our Lord God, 1684, being Leap Year," by Thomas Aldersey, barrister, who lived from 1634 to 1715, and whose portrait is at Aldersey Hall. He gives a list of about 150 Apples grafted during April of that year in "orchard," "graftyard," and "hedgerows," on "Crab stocks," "ye stand stocks in higher orchard," "ye great Crab tree," &c. The names given are Redstreak, Golden Redstreak, Red Redstreak, Brombro Crab, Bodnam Crab, Golden Rennet, Marygold, Harvey Tarpley, Golden Pippin, and Ginnet Moyl. Another entry towards the end of the book appears at first sight to relate to the garden "Aristolochia, Turmerick," but a closer inspection proves it to be a recipe for a "purge for mare." This Almanack, "Printed by Mary Clark for the Company of Stationers," is a thin leather-bound book, 4 inches by 2 inches, fastened by metal clasps, and the writing being in a small, cramped hand is not easy to decipher.

The long range of glass comprises greenhouse, early and late vineries, and stove, this latter containing, among other things, a fine plant of *Crinum erubescens*, which flowers nearly the whole year through. In the late vinery Peaches and Nectarines are grown on a trellis below the Vines, and very fair crops of each are obtained, as well as of late Grapes, the lateral growths of the Vines being trained to the main stems in order to give light to the trees beneath. The propagation of hardy plants is extensively carried out, recourse being had to the nurseryman only for new plants and varieties. In this work the gardener, Mr. J. Chisholm, is very successful, and is well supplied for the purpose with pits and frames in a convenient and sheltered frame-yard.

The kitchen garden has very substantial brick walls 14 feet high, that on the south side being 2 feet thick, with three sections of parallel flues throughout its length of more than 90 yards, formerly heated by furnaces. Adjoining this wall and running parallel to it for half its length, is the herbaceous garden, separated by an archway of Hops from the Rose garden, through which runs a long path leading up to the Cedar tree. On the further side of the Rose garden is a long rockery which, in the spring and early summer, is a sheet of colour with creeping plants and choice alpine, and has a background of Penzance Briars and Pillar Roses.

There are many fine trees in the garden, some of the most noticeable being a Cedar of about 80 feet in height, with girth of 15 feet, and diameter of branch-spread 83 feet. This is a well-proportioned tree on all sides, and in spite of its great spread of branches has never been damaged by wind or snowstorms. At 4 feet from the ground the trunk divides into four main stems, and the girth given is the minimum below this point. A handsome Wellingtonia more than 70 feet high with a girth at 5 feet from the ground of 8 feet 3 inches, and 24 feet diameter of spread of branches. A *Taxodium distichum* has a trunk 4 feet 5 inches in circumference at 5 feet up.

The chief features of the garden are the rockeries and borders and beds of hardy plants, among which may be mentioned

Daffodils.—A collection of more than sixty varieties is grown in beds on a long border under a west wall on one side of a path, while on the other side many kinds are grown in a natural way in the grass. Mr. Burbidge's advice to raise seedlings is taken, and seed is sown every year.

Sweet Peas.—The leading varieties have been grown for a number of years, and many others raised by cross-fertilisation. Whether autumn or spring-sown all plants are raised in pots. Prizes have been taken for Sweet Peas whenever exhibited at the principal flower shows, including nine prizes at Earl's Court and Eckford's Challenge Cup, and two first prizes at Shrewsbury last year.

Roses are grown in quantity, principally decorative kinds of the Hybrid Tea, Tea, China, and climbing classes. In addition to those budded on Briar stocks, a large number are raised from cuttings.

Delphiniums are raised from seed saved from the best flowers every year, and are grown in masses in separate beds.

to know the habits of different plants, so that each plant may be put in that position in the garden which is best suited to it, but this needs some years of experience, and even then one needs to know the differences of soil in one's own garden. I have seen sun-loving plants like *Nasturtiums*, *Rock Roses*, and *Eschscholtzias* growing in a damp, shady position, where they did little but produce leaves, and in the same garden I have seen Japanese Plantain Lilies, Lenten Roses, double Meadowsweet, and Lilies of the Valley being literally burnt to death in a hot, dry position. All these things would not only have done infinitely better, but would have succeeded instead of failed if one set had changed places with the other set. There are probably few gardens where there are not some anomalies of this sort, so much labour being wasted in trying to make things grow in soils and positions to which they are not suited. The extreme dryness of a given piece of ground is generally owing to the absorption of its moisture by the roots of large trees, though the latter may be so far from it or so situated that the ground is baked by the sun at the same time. Such a piece of ground should be turned out to a depth of 2 feet, and the

IN THE FLOWER GARDEN AT ALDERSEY HALL, CHESTER, THE RESIDENCE OF MR. HUGH ALDERSEY.

Autumn Phloxes are also raised from seed, though many of the best named varieties are grown. Some plants of *Romneya Coulteri* form large bushes under a south wall on a sheltered border, and, together with *Choisya ternata*, flower profusely.

The soil of the garden is heavy loam on clay subsoil, and requires thorough drainage in order to grow anything to perfection.

## PLANTS FOR DRY PLACES

IT is a common thing to hear it said of some particular part of the garden that it is so dry that nothing will grow there. This is never the sole cause of the bareness of any part of a garden in England. Some parts may be too rocky, sandy, or chalky, but where there is actual soil anywhere in this country there are many things that may be grown. It is a great secret of successful gardening

bottom well broken up with a pickaxe, a few barrow-loads of exhausted light-coloured soil being taken out, and a quantity of good rotted manure well mixed with the soil which is put back into the hole.

There is nothing like deep cultivation for overcoming drought, and in such a case as this it will also get rid of a great many of the roots which cause the dryness. This is assuming that the roots are of no consequence, such as those of Horse Chestnut trees—surely the most absorbent of all with their masses of fine fibrous roots penetrating every inch of the surface-soil within reach—Yews, Hollies, and the like. After such treatment the border will do well for a couple of years if the right things are put into it, and fairly well the third year, after which it will begin to languish again. But if the border is on the sunny side of some choice shrubs, and perhaps within reach of some hungry tree-roots as well, we can only make the best of it.

But there are positions worse than this, namely, under the shade of evergreen trees, Cedars, and coniferae of any sort, Portugal Laurels, Hollies,

&c. In such situations it is quite out of the question to think of growing flowers in the summer time. We may grow the Winter Aconite (*Eranthis hyemalis*), Snowdrops, and old-fashioned Daffodils for a year or two, and perhaps Primroses and Polyanthes if it is a retentive soil and we plant them afresh every autumn. But these all die down and leave the place bare in the summer, perhaps all the more untidy for having the dying leaves of the plants that try to survive. As a rule the bulbs will not bloom more than two years, though they may often have their duration prolonged by a dressing of basic slag in the autumn or superphosphate in the spring, as the soil in such positions is almost destitute of phosphate, and this is absolutely necessary for bulbs if they are to produce anything but leaves. The best thing in such cases is to be content with covering up the ground without hoping for anything more than a few bulbs in the early spring. There is nothing to beat some of the Ivies for this purpose, of which there are now a score or two of varieties to choose from, some of which are really beautiful foliage plants. The covering of the ground with Ivy need not prevent the planting of some bulbs underneath it every autumn, especially some of the Scillas, notably *S. campanulata*. Another thing almost equally good for such positions is the *Berberis Aquifolium*, with its brown-tinted foliage, so beautiful for cutting in the winter to mix with late *Chrysanthemums*, early *Narcissus*, &c. Both of these take a couple of years to get established in dry places, but, once established, they may be relied upon to keep the ground covered without any further attention, while the leaves from the trees above will afford them nourishment, though this may be supplemented by an occasional dressing of manure or basic slag, preferably both. The recommendation of both these plants is based upon the assumption that the position is not dark, but gets plenty of light, if not direct sunlight. The Rose of Sharon (*Hypericum calycinum*) will carpet the ground under most trees, but under the shade of conifers it is a veritable struggle for existence, and it may or may not succeed. The same may be said of the various sorts of Periwinkles, and also of the little Woodruff.
